brench has been enlarged. Eighty mon were employed in the work. The ditch has never before been in eo good a condition aa now and its carrying oapacity is somewhat increased. It cannot be long before water will be abnndant, and miners should have their claims in readiness to use it as soon as a enpply can be obtained.

EL DORADO.

A Bright Futuar.—El Dorado Cnnnty *Republican*, Oct. 7; The mining intereat in this conuty looks bright for the fnture. Never, we believe, were nur minee in ae good condition for being thoronghly and economically worked, and will add no emall amonnt to the millions to be added to the world's wealth dnring the next year.

New Mines.—Folsom *Telegraph*, Oct. 9: We nnderstand thet a new qnartz ledge has been disenvered near Pilot hill, in El Dorado cnnnty; the qnartz prospecte abnnt $100 per ton. Parties have offered a good prica for the mine, but tho owners, one of which is a resident of this town, prefer putting np a mill and working the mine themselves.

FRESNO.

The Confidence.—Fresno *Expositor*, Oct. 13: The Confidence mine, nn the Fresnn rlver, located by Dodds and nthers, has passed into the hande nf Mark Howell and J. B. Coonanonr. The shaft on the mine haa been snnk to a depth nf 75 ft. At that point the ledge ehows a width nf more than 7 ft, and haa well defined slate walls. The nre looks as rich na avar, and all appearances indicate the mine to be a permanent one.

MARIPOSA.

Canal and Tunnel Work.—Mariposa *Gazette*, Oct. 9: We have not been advised this week of the progress made in the great undertaktng known ae the river tnnnel; bnt learn that the hardness of the rock is undiminished, and the dietance gained abont the same as the week previons. Thls is certainly a great nndertaking, and when oompleted will certainly pay the Mariposa land and mining company handsome dividends, for the richness of the Pine Tree and Josephine veins which the tunnel will strike, has been tested and proven for many years. Thie fact is what encourages the company to prosecnte the work with so much energy. Several other veins, amongst them tha celebrated "specimeo ledge," will undoubtedly be opened before long. The company has now a large force of men at work constructing a road along the line of their proposed canal. It haa for many years been a wnnder to ordinary minors why the *scientific* engineers whn in years past controlled the working nf the grant, did not construct this canal, as, by that means, they wonld have a natnral bulkhead, and nne there would be no daoger of a flood waehing away. Work will ba in full blast on the canal in a few days.

NEVADA.

Prospect Company.—*Foothill Tidings*, Oct. 9: The Prospect company recently began work on the old Perseverance mine, situated between Allison ranch and Forest springs, and have thia week reached the ledge in the old tnnnel, where the rock is believed to be of milling qnality and will be taken out for that purpose. The Perseverance was at one time a mine of worth and etanding among mining men here, and shares therein commanded good rennd aume. Lack of even an elementary knowladge nf mining on the part of those in charge at the time, cansed a smash-up and collepse, firet of the underground timbers and works, and as a conseqnence, of the company. The Prospect oompany recently obtained title to the mine and are going to work the right way to develop it. The Prospect boys are certeinly deeerving of a good mine, if grit and backbone ever merit reward, and from all we can learn of their present venture they are hound to have one soon.

The Blne Banka mine, nne nf the deepest gravel deposits at Moore's flat, has a channel 300 ft long and about 70 ft deep in the center. The ownera, Meesrs. Wm. Rankin, Wm. Pryde, E. Mills and Jamee Reid, have recently completed a new tnnnel, 1,000 ft in length, throngh which they will be able to work their olaim to the bottom, and the claims adjoining if need be.

A tunnel ie being run in at Moore'a Flat to open np aome old gravel mines which have been idla for eome time for want of grade to waeh up their bottom dirt. The Ohio, a once paying and still rich and extensive olaim, owned by Atwater & Knotwell, will thus be enabled to send out the remainder of its great wealth.

PLACER.

The Julian Mine.—Placer *Herald*, October 9: Owing to the break in the Bear river ditch, which ont off the water enpply in this section for the time being, the Julian mill hae been compelled to lie idle more or less, lately, up to the early part of this week. In the meantime, eome 450 toos of ore have accumulated on the dump, which, in addition to the regular daily yield, will keep the mill running at its best licke for a long time. This mine, down to the 230-ft level, aa deep as developed until very recently, shows the largest ledge and the most uniform in size and yield of any in this part of the country. The vein, posseseing neither rich nor barren streaks, can alwaya ba relied on for from $7 to $10 per ton. This, considing the size of the ledge, whioh ia never less than two, and in most places three feet, ie a profitable yield. Mr. Schnable, the owner, hae recently commenced to sink the sheft 110 feet deeper, and, notwithstanding the fine character of the mine above the 230-ft level, the prnspects brighten ae they go down. At the bottom of tha shaft, at present, the ledge is nver three feet thick, and the rock prnspecte fnlly as rich as the best yet taken frnm the mine.

In Full Blast.—The Anburn gravel mining company commenced washing on Tunnel hill last Tuesday, and may now be said to be running in full blaet. What they did on Grizzly hill can be conoidered no more than preliminery to the great work before them. That hill was small and shallow, bnt it answered the purpose of teating the natnra and richness nf the gravel beds they propose to develop. Tnnnel hill, on which they are now nperating, contains, we shonld judge, nearly 100 acres of gravel, averaging nearly 100 feet in depth. Being satisfied of tha richneee of the depoeit, the company have apared neither pains nor expense in fitting np, and have, though not quite the largeet, without donbt, the best hydraulic works in the Stato of California to-day. On turning on the water, lest Monday, everything worked like a charm. Tha gravel in this hill is small, a bnulder larger than a man's head being a rarity, and "cuts," ae miners call it, rather easily. With the two giants they will move dirt very fast.

TRINITY.

Rich Cinnabau Deposit.—Trinity *Journal*, Oct. 9: The Trinity quicksilver company have strnck a rich and probably extensive deposit of oinnabar in their mine. Experts say it equals anything yet found in the Altooca mine. One thnusand dollars has been offered and refoeed for one-tenth of the Trinity mine. We are pleased to chronicle the snccess of thie company, as the stnck is all owned at home.

Nevada.

WASHOE DISTRICT.

California.—Gold Hill *News*, Oct. 7: The main north drift on the 1550-ft level is again advaocing toward the Ophir line, the face in rich ore. Tha botinm of the winze below oroscent No. 3, nn the 1550-ft level, ie down 90 ft, the bottom still in rich ore. There is considerable flow nf water at the bottom of this winze, which makes the sinking quite slow and trnnblesome. Prospecting the 1500-ft level is almost completed, if we except the timbering and enlarging nf snme of the drifts. The main north drift on the 1400-ft level is steadily advancing, and is oow within 110 ft nf the Ophir line, the face in low grade ore and qnartz. Raiees are being made on the nre body above the 1300-ft level for the nnrpose of nscerteining the character and lay ledge in that portion of the mine. Sinking the C. & C. shaft is making good progress. The new pump worke to the utmost perfeotion, and ie an immense and nndoubted improvement over the old style of pump. The battery mill is fast approaching completion, the boilers all being in place and the smoke stacks now being raised. The amalgamating mill ie also nearly ready to start up.

Con. Virginia.—Daily yield 600 tons of ore. The ore breasts are looking splendid, and there seems no let-up in either the richness or the immenee quantity of the yield. The yield for the past month will foot up about $1,812,000—a pretty good showing for one mine, which ie mede eo much better by the well known fact that the yi ld oonld have been easily increased to $2,000,000 if the management so desired. There is no proepecling done in the mine at present but there have already been winzes sufficient eunk below the 1550-ft level to prove the continuance of tha bonanza, 100 ft below the 1550-ft level, and how much farther none oan yet determine. Two new mills, the Morgan and the Brnnswick, have been nurchaeed and added to the orneliing capacity of the Pacific mill company, which, as soon ae tha weather cools and the water rises in the river, will add greatly to the yield of the mine, or if the company do not wish to increase the already magnificent yield of their mine, can then be used to reduce the rich ores of the California.

Sullivan.—The sbaft ie now a little nver 50 ft deep. Last Sonday it very unexpectedly ran ont of the conntry rock into a heavy body of quartz, clay and other vein matter the width of which is not yet ascertained. It contaioe very promising feeders of qnartz from 2 to 6 inches wide, which assay well in gold with a proportion of silver. The whole bottom of the shaft is in it. Superintendent Keleey did not expect to strike this Sullivan ledge under 200 ft from the snrface, therefore jnetly conoiders this promising strike of vein metter as a very encouraging and aignificant circumetanoe. The grading at the surface for the hoisting works buildinge, ato., progresses well aod an excellent road bae been made to the mine from the railroad, for hauling timbers, lumber, etc.

Overman.—The new spur wheel to supply the place of that broken a week or two since was recoived at the mine yesterday, and will be in its place and everything in complete ronning order by to-morrow. The water haa been rising slowly in the shaft, so that it will take but a very short time to free the shaft from water when once the pumps are again in full operation. The south drift on the 900-ft level has been steadily advanoing, the face in hard blasting ground. The south drift from the bottom of the winze on the 1100-ft level hae been advanced 27 ft during the week. No developments of interest to report.

Amazon and Glasgow.—The main shaft has reached a depth of 100 ft below the first station level, and preparations are being made to open another statioo and start a drift to cross-cut and prospect the ore vein at that point. This will give a depth of 309 ft from the surface and will open the mine 100 ft deeper then it hae yet been prospected. Taking intn consideratioo the excellent ore prospects found on the first statinn level, it ie confidently expected that when the new station is npened good paying ore will be devaloped. The machinery is all in good order and everything in and about the mine working well.

Julia.—Sinking the shaft ie making splendid progress, a considerable portion nf the bottom being in a very favorabla character of qnartz and ledge matter. The indications are strong that the shaft will soon cnt the main ore vein. The main sonthweet drift on the 1400-ft level ie steadily advancing, with better prnspects of a good ore development than at any time in the past. The main sonth drift on the 1000-ft level is also making good progress, the face in a mixture of qnartz, cley and porphyry of a very encouraging natnre.

Utah.—The work io thie mins is principally confined to sinking the shaft at present. The rock in the bottom etill blasts out well and good progress is being made with the sinking notwithetanding a strong flow nf water. The pump continnes to handle the water with eaee, and the sinking is being prosecnted with all the vigor possible to reach a point at which to start a new level nt the earliest moment that it can be accomplished.

Ophir.—Daily yield, 350 tons of ore. This ore is being mostly extracted from above the 1465-ft level, and is of a fine character. The ore breasts are looking splendidly, and promise a good yield for a long time to come. An upraise has been made on the nre body above the 1300-ft level. This raiee is now np 90 ft, io splendid ore, with no apparent indication whalever of its giving nut. The raise is on the west sida of the ore, and the inclination proves the ore to lie at least 200 ft frnrther to the eastward than any prospecting that has ever been done on the 1100-ft level, and donble that dietence eeet of all the old proepecting work done on the 700-ft level. This bit of prospecting is bidding fair to open up a new era in Ophir affairs, ae the determinstion of the ore vein eo far tn the eaetward is giving 700 ft perpendicnlar of virgin untouched ground for prospecting, with every apparent indication of catching a portion of the top of the great California and Consolidated Virginia bonanza. The old 1100-ft station has been reopened and a new drift started sonth with six-hour shifts of men, to strike this new ore body. Should the body of ore prove to hold its width and richnees at that point, the old 700-ft station will probably be opened up and new works commenced to the eaetward there. On the 1700-ft level only one drift is being rno to the eastward at the present, but in a few days more it is the intention to commence work agaiu on all the levels in good earneet, and drive the prospecting of the mine to completion at all points with all the energy possible. The new and powerful pnmping and incline machinery are nearly completed, eo that in a few days more the dead work expensea on the surface will be greatly lessened, which will give a better chance to work more men in the mine without an additional increase of expenses. The mills are all steadily running and are crushing abont 310 tons of ore per day. The returns of bullion will double this month that of any previous month's work for the paet two years, and the prospects of Ophir are once more brightly in the ascendent.

Justice.—Face nf drift at 800-ft level is in low grade ore, which improves with advancement, and bids fair to fornish ore for milling very shortly, assays averaging from $25 to $30 to the ton. Water does not interfere. In all probability this drift will soon run intn the ore body developed above in the old mine. At the 600-ft level, this ore bndy is estimated to be at least 50 ft wide, bnt its real dimensions are not yet ascertained. At the 400 ft level it is 40 ft wida, and at the 200-ft level, 10 ft wide. At the 400-ft level it is 130 ft long, whioh is ite greateet defined length as yet, with the face of the drift still in rich ore.

New York Consolidated.—The powerful new machinery is now about all in position, ready for working, and will start up for the first time next Satnrday. It will take about two weeks to free the shaft of water, when sinking will be resnmed. The extensive ore developments found at the 600-ft level of the Justice mine, as well as in the two levels above, is considered of great importance to the New York, as the indications are that it extends into this mine, and that a portion of it had already been struck in the shaft befora einking was snspended.

Sierra Nevada.—The Ingereoll drille are now being used in both the west drift on the 1000-ft level and the bottom of the new shaft, and are giving the most perfect satisfaction. Good progrese is being made both in running the drift on that level and in sinking. The north and south drifts on the 700-ft level of the old shaft are both steedily advanoing, without change of value to record. Everything in and about the mine looking proeperous.

Chollar-Potosi.—Daily yield, 50 tone of ore the aesay valne of whioh ia $30 per ton. This ore is mostly extracted from the old upper workinge. The three sonth drifts on the 1150, 1250 and 1350-ft levels are steadily advanoing without change of interest to report. Sinking the combination shaft is making rapid progrees, the rock in the bottom workiog qnite soft. The hoisting works building and other surface worke are fast approaching completion.

Savage.—Sinking the main incline has been stopped during the greater part of the week by the tapping of a etrong pocket of water at the bottom, the flow from whioh keeps the pump steadily at work. The indioations are, however, that the pocket will soon be drained and the sinking resumed. The two north drifts on the 2100 and 2200 ft levels are steadily advancing without any material change of value to speak nf.

Caledonia.—Sinking the main shaft is making good progress, it has been sunk dering the past week 31 ft. The rock io the bottom is qnite tongh and herd. Good headway is being made in cntting out for the pump and water tank at the 500 ft station. It will not now be but a very ehort time before the new pumping machinery will all be in complete rnnning order. The new hoieting engine ie working with the ntmost perfection.

Belcher.—Work was resumed at all points in the mine day before yeeterday, everything working with as great a perfectiou ae it was possible. Only about 140 tone of ore per day is being extracted, as only that amount is required to keep the mille running. Prospecting the 1600-ft level hae been again commenced in good earnest. The machinery is now all in excellent order, and everything else in fine working condition.

Florida.—The main west drift is being pushed directly ahead into the regular ledge matter. It shows great improvement with every foot of advancement, and high aesays are obtained from the feeders nf quartz passed through. The main nra vein is ovidently close at hand, and Superintendent Nagle is very confident of finding a bonanza before long. He certainly has good reesone for soch expectations.

Gould & Curry.—The repairs which it was believed were almost completed a week ago still hang on, meny of the timbers having been steamed and rotted by the vapor and heat of the mine to such an extent that they will have to be removed end new onee substituted, all of which takes time. But little prospecting or cross-cutting can be done nntil the repairing, which is extremely slow work, is completed.

Bullion.—Sinking the main inoine goes steadily forward at the same favorable rate of progress as heretofore. The face ol the main north drift is steadily advancing along the west wall of the ledge, in qnartz and ore of a very favoreble character. The Alpha combioation drift on the 2000-ft level of the Imperial is again steadily advancing.

Imperial-Empire.—Daily yield, 40 tons of ore, the aseay valne of which is from $60 to 85 per ton. The ore breasts are all looking well. A raise has been completed from the 1900-ft level to connect with the ore etopes, which greatly assists the ventilation of that portion of the mine, and aids the extraction of ore. Nothing new to report of any of the other proepecting operations.

Dayton.—The pumping machinery started into full operation and sinking the shaft was resumed last Satnrday, since which time everything hae been running with all the smoothness and precision of clockwork. The sinking is going forword at the rate of 2½ ft per day, and no more tronble from an overflow of water is now apprehended.

Silver Central Cons.—Drifting west at the 175-ft level ie actively commenced and progressing finely, with flatteriog prospects, stringers of fine looking quartz already making their appearance. The indications are favorable for striking the ledge at an early day. Work is vigorously pnshed ahead, and the machinery operates smoothly and eatisfactorily.

Hale & Norcaoss.—Prospecting and crosscutting the 2100 and 2200 ft levels is still progressing as rapidly as it is possible to accomplish such work. The ledge nn the 2200-ft level is wide, and of a good character of quartz, affording low assaye of both gold and silver, bnt as yet developing no ore that will pay for extraction and milling.

Buckeye.—Sinking the sbaft is making good progrese, meny seams of qoartz rich in gold being enconntered in the bottom while sinking. The chancee for finding large bodies of pay ore at a greater depth are evidently on the increaee. The flow of water is steedy and strong, but it is drained by the pump with great eaee.

Crown Point.—The usual amonut of ore is being extracted and milled. Little or no change to report of any of the ore breasts or old upper workings. Prospecting the 1600 and 1700-ft levels affords no new or valueble developments to report for the week. The work is being energetically advanced at all points.

Yellow Jacket.—Sinking the north and south winzes on the 1740-ft level is progressing as usual, without any material change of value to report. Neither is there any new developments in report of any of the croee-cute on that level. The water in the incline remaine about the eame.

Sutro Tunnel.—Total length to-day, 11,091 ft. The face of the header continues in the same soft and treacherous ground, slipping and caving very easily. Very little blasting has to be done, and great care is exercieed to keep it well secured and prevent accidents. No increese of water.

Peat has been successfully used in a locomotive of the Southern Pacific railroad company between Oakland and San Jose. Three hundred pounds of peat sufficed to make the trip, keeping up a hot fire all the way, and running at the rate of forty miles per hour.

The surveyors began last week, at Guerneville, the work of locating the narrow gange railway for the extension of the Tomales line, from Austin creek.

The Southern Pacific railroad company are sinking an artesian well at Colton, San Bernardino county.

The Cryptograph.

The srt of secret writing, or, in other words, of corresponding in ciphsr, has long been practiced, and considerable perfection has been attained in it. There are various methods of conducting it, each being more or less meritorious, and, to a certain extent, impenetrable; bnt the best among them carries with it the objection of being more or less complex, and thereby lisble to error either in composition or translation. Moreover, tbere are very few systems upnn which perfect reliance can he placed for secrecy, inasmuch as the modes of their construction and the nature of the principles upon which they are based render their solution possible by others than those by whom they are being used. Again, in cases where assistance is reqnired in conducting secret correspondence, shonld an official be dischsrged and be disposed to act dishonorably, he might render himself invaluable to others than his late employers by so doing. In a word, we have not down to the present time succeeded in producing a system of secret correspondence which cannot in time be nnravelled by others than these in possession of the key.

Such a system, however, it would seem is now being introduced by its inventor, Mr. A. L. Flamm, at whose rooms at 123, Pall-mall, was recently shown its working. The principles of this system may be best described as a simple mechanical manipnlation, and the variation and extension of which it is capable are comparatively unlimited.

The mecbanical portion of the system consists of a rectangular tablet divided by lines into a certain nnmber of squares. Around its edges is a raised rim, on which are marked figures corresponding horizontally and vertically with the squares. A metallic plate of the same size as the tablet, and capable of exactly fitting within the raised rim, is divided up into squares corresponding with those on the tablet. In some of these squares holes are pnnched in the most irregular and inconsecutive manner, their arrangement being purely arbitrary. Tbese holes are round and are of sufficient size to enable a good sized letter or figure to be clearly formed through each opening. The plate has the figures 1, 2, 3, 4, placed, one at each corner, which have reference to its manipulation. This apparatus is of various sizes, from that of twelve centimetres square, which is hinged and fitted as a small pocket book, to that of thirty centimetres square, or of any larger size that may he desired, arranged in the form of a portfolio. In uso a sheet of paper of any size is placed upon the tablet, and the metallic plate is laid upon it—in the first position, or with tbe figure 1 in the left hand corner. A message or communication is then written letter by letter on the paper, each letter being traced in each successive hole. As soon as tbe last hole has been nsed the plate is tnrned aronnd, so that the figure 2 comes in the left hand top corner. The paper now shows a number of letters at irregular intervals whicb form consecutive words. After the holes have been again filled the plate ie shifted round to the third position; the paper will now show double the nnmber of letters, which will appear a little less irregular; bnt consecutive words cannot now be made ont, other letters having been interspersed with them. The plate is now shifted successively to the third and fourth positions, and after the fourtb operation of the pen or pencil the paper will be fonnd to be covered with a heterogeneous assemblage of letters and figures, but all placed in true horizontal and vertical line. If tbe message is not completed, any additional number of sheets of paper can be nsed. These can then be dispatched in the usnal way, and when tbey arrive at their destination, the recipient, being in possession of an apparatus identical with that in which they were written, places them one by one on the tablet, uses the perforated plate in exactly the same way as the writer did, and quickly spells out the communication.

In transmitting a telegraphic dispatch by this system, the sender first writes tbe message, letter by letter, on a small piece of paper divided into sqnares of the same size as those on the tablet. The perforated plate is then laid over it in position No 1, and such letters as appear through the perforations are written down by groups of five on a telegram form; five letters counting as one word in cipher telegraphic dispatcbes. The plate is then placed in successive positions until the message nas been written down in this way. Upon the message reaching its destination, its recipient takes a piece of equared paper of the same size as that upon which the message was originally written—the size having been previously agreed upon between the parties. Upon this he places his perforated plate, and through the perforations he successively writes down the letters as they appear in the telegram before him until the four changes have been made, when, assuming the telegram not to require a second piece of paper, the message in perfectly consecutive order is revealed on the paper before him as originally written. There are various other ways of using the system; modifications, in fact, of what we have already described—such as using a special shape of paper or having an arbitrary design upon the paper within which the message shall fall. Of these, however, it is not necessary here to say more than that they are very ingenious, and serve as an additional means of baffling the onrious and unauthorized investigator.

The figures round the tablet refer to a modification of the use of the apparatus. For instance, if two correspondents wish to go a step further in secrecy, they could arrange the work within the range of a limited nnmber of squares, say from three to ten, and they could previously give them the arbitrary designations of B to P, or define them in any other way. The holes in the plate are, we have said, purely arbitrary; they are, however, referable to and governed by what Mr. Flamm terms the graphic table. This table is really the basis and starting point of the whole system, it ie the fundamental principle of it, and the sole key to it, and its possessor can construct any nnmber of varieties of plates each having a different arrangement and being of a different size from the o hers. This graphic table is a sheet of cardboard of the same size as the plate which is to be perforated from it, and is divided up into a number of squares variously colored and numbered. From this simple looking table—into tbe mysteries of which we have not, of course, been permitted to dive—Mr. Flamm assures us that any one is capable, after initiation, of constructing any number of perforated plates giving an infinity of changes. He states that the small apparatus twelve centimetres square is snsceptible of no less than 4,722 trillions of changes, while the large one, thirty centimetres sqnare, will give a number of permutations expressed by 4 raised to the 225th power. Mr. Flamm thus has the apparatus for those who only have a comparatively limited use for cipher communication, while for governments and banking houses or other large establishments he has the secrets of the graphic table to communicate.—*English Paper.*

Kid Skins for Tanning.

In certain parts of Europe tbe rearing of kids for the sale of their skins is an important business, those which command the highest prices, and are regarded as snperior to all other, being the French, called in the market *peaux nationales*. By some the fine quality of these skins is attributed to a peculiar virtue in the wild vines npon which the young ones feed in the pasturage which they frequent; this, however, being a popnlar error, as their value is simply the result of the care with which the little animals are reared during their life of four or five weeks. They are not allowed to roam at large, as such a license would imperil the evenness of their skins, which would become scratched by rnbbing against stones, or passing tbrough hedges. They are, besides, deprived of all food except milk, as eating grass would tend to render their skins coarse. Consequently they are kept under a wicker coop, from which, at regnlar hours, they are led to snckle the mother, and this continues until they are killed, at the end of four or five weeks. The younger they are killed the thinner the skin, but, of course, the smaller tbey are the less valuable, too especially when they are only large enough to allow of single-buttoned gloves. By rearing the kids in the manner just described, larger skins are obtained, which are as fine and delicate as those of younger ones, of other countries where they roam at liberty. As France produces the best skins, so Paris excels all places in France where gloves are manufactured, and an adept in the trade can select a Paris made glove from among hundreds made elsewhere.

Potency of Sunshine.—From an acorn we gbing a few grains, a tree will grow for 100 years or more, not only throwing off many pounds of leaves every year, but itself weighing several tons. If an orange twig is put in a large box of earth, and that earth is weighed when the twig becomes a tree, bearing luscious fruit, there will be very nearly the same amount of earth. From careful experiments made by different scientific men, it is an ascertained fact that a very large part of the growth of a tree is derived from the snn, from the air, and from water, and very little from the earth; and notably, all vegetation becomes sickly, nnless it is freely exposed to sunshine. Wood and coal are but condensed sunshine, which contains three important elements, equally essential to both vegetable and animal life—magnesia, lime, and iron. It is the iron in the blood which gives it its sparkling red color and its strength; it is the lime in the bones which gives them the durability necessary to bodily vigor, while the magnesia is as important to many of the tissues. Thus it is, that the more persons are ont of doors, the more healthy, the more vigorous they are, and the longer will they live. Every bnman being ought to have an hour or two of sunshine in winter, and in early forenoon in summer.

The Absorption of Water by Woody Fiber. In alluding to the force which raises the sap from the roots to the foliage of trees a noted writer says:

"One of the most surprising facts to be noticed in examining the wood of any tree with well-developed foliage, is the absence of anything like free, or fluid water. A freshly cut surface of sap wood is not even moist to the touch, and if a tube be inserted into the trunk of such a tree it will frequently absorb water with great avidity. On the sixth of June last a half-inch tube, six feet in length, was attached to a stop cock inserted into the trunk of an elm and the tube filled with water. The absorption was so rapid that the fluid disappeared in thirty minutes, and this was repeated several times the same day.

"Now, this absorption was not osmotic, but apparently the result of imbibition or the affinity of the cellulose of the woody fibre. Is not this, then, the proper name for the force which carries up the crude sap?"

Government and the Phylloxera.

No slur upon the Government is intended in thus naming it in connection with the phylloxera, the second party in the heading of this article. The occasion which brings them together here, is the suggestion put forth by certain journals that the National Government appoint a commission to investigate their habits and discover, if possible, some method for preventing their propagation in this country.

Now, are not people justified in characterizing these demands on Government as merely clap trap, designed to catch the ears of the agriculturists? And is the National Government the proper source to look to for relief from these insect scourges? The propriety of France offering a reward of 300,000 francs for a successful remedy against the phylloxera is unquestioned; for the grape is to France what it is to California; and though it may be advisable for this or any other State largely interested in grape culture to make this prominent among the demands on their own Legislatures, they will probably receive little efficient aid from the general Government, if they do not have the "cold shoulder" turned to them. If our State agricultural colleges cannot meet these almost local wants, to what public source can we look for relief? For our part we should expect more aid in this emergency from private entomologists and vine growers, than from any public source whatever. Besides, we do not consider the emergency as critical as it is represented to be. There is certainly a mistaken notion prevailing in regard to the record of the phylloxera. A paper, which is particularly anxious to secure the appointment of a national commission, snch as we have alluded to, refers to "the government of France, where the same insect has done still greater damage, and from whence it has been introduced to this country with the imported vines." Twenty-one years ago the State Entomologist of New York, Dr. Asa Fitch, described the phylloxera as then found in various parts of this country on our wild grape vines; and it is now generally admitted that phylloxera in both forms—the one attacking and producing galls upon the minute fibrous roots, the other confining themselves to the leaves—existed in America prior to their career in France. Two very plausible reasons have been offered why this pest has increased more rapidly in France and has been more destructive there than in this country. First, is the mode of culture. The excessive pruning to which the vineyards of France have been subjected for generations, are believed to have weakened the constitutional vigor of the vine, and lessened its ability to withstand the encroachments of disease and insect enemies. Canes that are allowed to approximate their natural growth will not, of course, produce fruit that will compare with that of vines pruned after the French and California style, bnt they will tend to promote good, long roots and healthy rootlets; and this, as we all know, is a condition which effectually resists such attacks.

The other reason assigned for the more destructive career of this pest in France, is founded on the recognized principle that diseases and parasites on their first entering a country are more destructive than in those countries where both animal and vegetable life are accustomed to their presence.

In regard to the importation of the phylloxera, M. Signoret, an eminent French entomologist, makes the following sensible remarks:

"If, instead of ascribing the phylloxera epidemic to a few solitary insects, possibly imported from Ohio or California, viniculturists had dropped that part of science which consists in raising artificial boundaries, where nature has created none, and simply considered phylloxera in the light of vermin attacking a very diseased or weakened plant, they might probably have had recourse to the most rational way of ridding their vineyards of such pests by letting them alone—without pruning at all for a few years."

A recent monthly report from the Department of Agriculture calls for answers to the following questions, copied from the London *Wine Trade Review*:

"1. Is the phylloxera the cause of the new disease of the vine, or is it the result? 2. How is it to be accounted for that hitherto none of the insecticides applied, nor other means recommended, have been able to destroy it? 3. If the phylloxera is but the consequence of the disease, would it not be advisable to treat the affected vines prophylactically by means of powerful manure easily applied. 4. How is the destruction of the insect by snbmersion of the vines explained? 5. In what manner does the phylloxera carry the infection from a plant infected to a healthy plant? 6. Is the phylloxera that attacks the roots of the vines (the species best known in Europe) identical with the phylloxera that preys on the leaves (the species most prevalent in America)? 7. Are there one or more parasites of the phylloxera in existence and known to science? 8. Are there any species or varieties of the vine plant that successfully resist its attacks and defy contagion? 9. Would it be possible and practicable to multiply such varieties in France by grafting them on to the descriptions commonly planted in France? 10. Is it possible to calculate the money value of the losses occasioned by the phylloxera in the south of France? 11. What is the economic influence of the insect on the price and consumption of wine, on the traffic of the railways, and the revenue derived by the State from the tax on wine?"

Some of these questions do not particularly concern us; and in sending them forth the Department displays its morbid appetite for statistics. If the phylloxera were supposed to be readers of the Departmental Reports we might reasonably hope that they would be killed with figures; but from what is known of their habits we shall expect to have them suffer but little from this nor any other governmental source.—*Rural Press.*

Centennial Co-Operation.

The Kansas Pacific and Central Pacific railroad companies have joined together, and arranged for the erection of a building on the grounds at Philadelphia, separate from the regular halls of the exhibition, for the special purpose of displaying the products of Colorado, Wyoming, Kansas and Nebraska. The railway building will be two stories in hight, the first floor to be devoted to display, while the second will be devoted to sleeping apartments for the convenience of interested exhibitors. These companies will exhibit a vast array of minerals, cereals, agricultural and other specimens.

A delegation of progressive and wealthy Californians and Nevadians have been endeavoring, by vigorous representations, to indnce the Central Pacific to join the corporations first named and provide space by enlarging the building for a full display of Western products, but that company prefers to exhibit on its own hook. For the last eighteen months the land department of that road has been industriously seeking out and gathering together the finest mineral, cereal, ornithological and zoological collection ever secured on the coast. Besides this the exhibit will embrace—in fact already embraces—some of the largest collections of marine, land and fresh water shells ever shown. Moreover, specimens of the coals of the Pacific region have been secured. They represent fully one hundred different grades, from the finest Shasta to the commonest alate mixed stone. The timber of the coast is represented by specimens, green, polished and petrified. There are also cuts from old monarchs of the forest, whereon approximate estimates of the rainfall for two centuries past are made in the rings which indicate the yearly growth. To convince the incredulous ones of the accuracy of estimating the moisture of past decades and centuries by this method, a bnt cut is shown which was taken from a tree planted seventeen years ago, and the records of rainfall thereon engraved, compared with the annual registers preserved on paper by official meteorological societies. It is an easy task to satisfy the observer that the variation in the estimates is hardly perceptible, and on this basis the amount of moisture in the past is approximated.

It would require the space of an ordinary volume to mention the full list of specimens embraced in this collection, for they represent birds of every plumage, animals of every species, together with curious alkaline formations, pebbles, marble, polished and rough, sands one pumice, honey-combed lava light enough to float, fossilized fish, borings from artesian wells, curious relics of armor, breastplates, fossil reptiles, entomological specimens, etc. In the line of cereals, the tallest cornstalks and the heaviest sheaves of barley and wheat, together with threshed grain in properly-labeled bottles, are fitly represented. The mineral resources of the coast will be indexed by samples of copper and silver ore, gold quartz, nuggets, etc. The labor of gathering together the necessary specimens is not yet completed.—*Denver News.*

How a Swarm of Bees is Suspended.—The sight of a swarm of bees suspended from the branch of a tree, and so heavy sometimes as to bend it, is a surprising one, and the observer naturally asks how so great a weight can be supported, without apparent fatigue, by the few scores of bees that are fixed to the inferior surface of the branch. According to Dr Bourgeois (in *Les Mondes*) modern science estimates the amount of weight which can be supported by means of vacuum (of which the anchor on a bee's foot affords an example) at one kilogramme thirty grammes per square centimetre. Now the sucker of a bee's foot, magnified sixty diameters, represents a surface of more than a centimetre. Each bee having six feet, it will therefore be possible for ten bees to support the weight of one kilogramme. Thus, the phenomenon in question may be accounted for. We find the above abstract in one of our English exchanges. Dr. Bourgeois appears to have forgotten that in magnifying sixty diameters the surface is magnified 3,600 times; so that, assuming the other elements of the computation to be correct, it would take 600 bees, instead of ten, to support a kilogramme, or about two and a half pounds avoirdupois.

England gets all her supplies of peppermint oil from this country, and still she feels an occasional uneasiness about the abdominal region, especially when Disston sends his saws to Sheffield.

The Voracity of Pickerel.—According to M. Peapion, who has been practically investigating the subject, a pickerel will eat 47 pounds and four ounces of fish per pound of its own weight per year.

Useful Information.

Trades of the Past.

Half a century ago bellows making was a thriving trade. Every house had its pair of bellows, and in every well furnished mansion there was a pair hung by the side of every fireplace.

But as stoves and grates took the place of open fireplaces, and as coal was substituted for wood, the demand for bellows diminished, and the business as a separate trade, died out.

The same is true of flint cutting. Flints were once necessary, but only for tinder-boxes, and a tinder-box was as necessary for every house as a gridiron or a skillet. Every one who looks back to a childhood of forty odd years ago must remember the cold winter mornings when the persistent, crack, crack of the flint against the steel sent up from the kitchen an odor of igniting tinder and sulphur which pervaded the house. We have no more idea what became of the flint producers than of the old man of sorrowful memory, who, three or four times a week, called at our house with brimstone matches, for a penny the half dozen bunches. Both have completely vanished from the country.

Then, again, are gone the pin-makers, who, though they have been in their graves this quarter of a century, still figure in lectures and essays to illustrate the advantages of division of labor. Instead of a pin taking a dozen men or more to cut, grind, point, head, polish, and whet not, as it used to do, pins are made by neat little machines at the rate of three hundred a minute, of which machines a single child tends half a dozen.

Nail-making at the forge is another lost industry. Time was, and that in this nineteenth century, when every nail was made on the anvil. Now, from one hundred to one thousand per minute are made by machines. The nailer who works at the forge has but a bad chance of competing with such antagonists, and he would have no chance at all were it not that his nails are ten-fold tougher than the former.—*Investigator.*

TOILERS AND LOITERERS.—Six hundred millions of people on this globe constantly toil all their lives long, while 19,000,000 sit quietly and complacently by, gathering the results to themselves. The laboring classes constitute 7-10 of mankind, and in any revolution they have nothing to lose but their chains; as the lowest stratum in society cannot rise without causing the complete disruption of all superincumbent classes we cannot measure the magnitude of the revolution that liberty, justice and equality to these millions evolve. To-day they are waking from the lethargy of ages, moving with that healthy discontent that marks every step in progress, and for the first time in the history of nations, combining the world over.—*Mrs. Stanton.*

BUSINESS KNOW-NOTHINGS.—The man who groans over his poverty without taking a step toward bettering his condition, is justly considered as a good-for-nothing dunce. Had he sense, the more desperate his fortunes, the more energetic would be his attempts to improve them. What is true of individuals is true of classes. Business may be dull just now, but the laws of demand and supply exist, as they always have done. They may be operating somewhat peculiarly at present, but the long-headed merchant or manufacturer will study how they may be turned to his benefit, instead of croaking about actual difficulties and imagining others worse to come.

ACTION.—Men who have half a dozen irons in the fire are not the ones to go crazy. It is the man of voluntary or compelled leisure, who mopes, and pines, and thinks himself into the mad-house or the grave. Motion is all nature's law. Action is man's salvation, physical and mental. And yet nine out of ten are wistfully looking forward to the coveted hour when they shall have leisure to do nothing, or something only if they feel like it; the very siren that has lured to death many a successful man. He is only truly wise who lays himself out to work till life's latest hour, and that is the man who will live the longest, and will live to most purpose.

THE IDEA OF PULVERIZED FUEL NOT NEW.—Nearly twenty years ago, John Bourne, in his "Treatise on the Steam Engine," pointed out the advantage of blowing coal dust into a chamber lined with fire brick, so that it might be ignited by coming into contact with red hot surfaces, after having been mingled with quantity of air necessary for combustion. There are now several large manufactories in the United States using pulverized fuel for furnaces and boilers.

DIVERSITIES IN WOOD.—The varieties of wood are more numerous than most people are aware of. At the Paris exposition of 1867, there were, from forty five different countries, no less than 3,769 different kinds of wood exhibited, 95 coming from Europe, 252 from Africa, 858 from Asia, 966 from Oceanica, and 1,298 from America.

WHEN A HOUSE IS NOT A FIXTURE.—A house set on blocks, resting on the surface of the ground, not attached to the soil, and removable without disturbing the land in any way, is not realty; and also a portable fence is not a part of the realty.

JUTE CULTIVATION.—Eight hundred thousand acres of Indian soil are now under jute cultivation, producing an amount of fibre, which ultimately takes the form of 32,767,930 gunny bags, and an enormous quantity of matting, cloth, twine and paper. California alone pays annually one million of dollars toward producing this amount of raw material—every pound of which should be produced on our own soil and manufactured into sacks by our own people. The State Grange of Patrons of Husbandry, which held its annual session in this city last week, put forward some very sensible ideas with regard to the introduction of this branch of industry into this State. They propose the employment of convict labor in the manufacturing portion of the industry, as a direction for utilizing such labor in a manner least liable to conflict with any of the existing industries of the State.

PEANUT CULTIVATION.—Many thousand tons of peanuts are exported annually from the Gambia, West Africa. The largest portion is carried to France, where it is converted into "the best olive oil." Why not extend the manufacture of "olive oil" in this State. A substitute for the inferior article made from the peanut?

THE Missouri-Mississippi has been most appropriately called the great continental river-tree, which has its roots in the Gulf of Mexico, its branches reaching to the Alleghanies, the Rocky mountains and Lake Itasca.

AN effort is being made to acclimate the Florida cedar in Germany, as it furnishes the only kind of wood suitable for the manufacture of lead pencils.

Good Health.

The Pain of Death.

It is the observation of all who have witnessed many deathbed scenes that the last struggle is usually painless. There are exceptions, but they are few. The writer of this was once drowned to insensibility, and it is probable that the violent arrest of life in full health in that way is as painful as most other forms of sudden death. If one had to suffer the pain of drowning under circumstances where the attention would be fixed upon it, it would doubtless be found quite severe; but the whole energies and attention are directed to efforts to escape—a *determination* to escape in fact, so that the sense of suffocation, while highly disagreeable, is not what we would call intolerable. This resolute battle for life lasts as long as sensibility remains, and fully occupies the attention to the last. The grip of a drowning man is proverbial, which shows that the determination to escape is so intense as not only to attract attention from the pain, but to cloud the reasoning faculties. It is well known that hand to hand combatants feel little or no pain, even in receiving mortal wounds. This attraction of attention from self is common to almost all forms of death. A very good illustration of the effect of this is known even in so acute a pain as the toothache. The sufferer will be relieved by anything that fully arrests his attention—for instance the appearance of the dentist's forceps. But this pain extinguisher is far less potent than many others which accompany disease. Cholera is one of the most violent of diseases, but the patient very soon relapses into indifference. Many other illustrations might be cited. There is a great deal of irrational dread of the article of death. Those who have well grounded hopes of a better life should never give themselves a thought of uneasiness about the narrow stream. The most they will ever know about it will be that they have crossed without knowing it.—*Interior.*

INVALID'S CUTLET.—One nice cutlet from a loin or neck of mutton, two teacupfuls of water, one very small stick of celery, pepper and salt to taste. Have the cutlet cut from a very nice loin or neck of mutton; take off all the fat; put it into a stewpan, with the other ingredients; stew very gently, indeed, for nearly two hours, and skim off every particle of fat that may rise to the surface, from time to time. The celery should be cut into thin slices before it is added to the meat, and care should be taken not to put in too much of this ingredient, or the dish will not be good. If the water is allowed to boil fast, the cutlet will be hard. It takes two hours' very gentle stewing.

DYING FROM A MAN'S BITE.—Yesterday, says a late number of the Washington *Star*, Dr. Newman, of the West End, amputated the right arm of Gilbert L. Joy, a colored man, who was bitten on the thumb by Josiah Edmonson, another colored man, some two weeks ago, in a fight. Gangrene has progressed to such an extent, however, that the physicians have no hope of his recovery. Edmonson was arrested after the doctor gave his opinion, by Officer Deaton, of the Fourth Precinct, and will be held to await the result of Joy's injuries.

BILE IS NATURE'S CATHARTIC.—Constipation frequently results from its deficiency. The office of the liver is to purify the blood by extracting bilious matter, which is brought to the service of the bowels for their daily action.

Scrofula.

Among the most terrible of the ills that afflict humanity is that too common, tedious and multiform disease, scrofula:

Pre-natal, or hereditary in its nature, insidious in its approach—and generally incurable; it is more to be dreaded by far than small-pox or yellow fever.

The name scrofula is derived from the Latin word scrofa, or scropha (a sow). Why, nobody knows. For hundreds of years people superstitiously believed it curable by the touch of some royal personage; hence the name "King's evil."

The characteristics of scrofula are a tendency to swelling of glandular portions of the system, which suppurate and discharge a curdy or mixed matter, and are exceeding difficult to heal.

Persons naturally or hereditarily subject to scrofula have, especially during childhood, pale complexions, large heads, narrow chests, protuberant bellies, soft flabby muscles and feeble circulations.

It is often indicated by red or light hair, grey or blue eyes, with large pupils, a fair transparent skin and rosy cheeks—but their rosy cheeks are very sensitive to cold, changing in a few moments of exposure to a purple or livid color, and are extremely liable to chills and chilblains.

Sometimes scrofulous children have dark muddy complexions, coarse black hair, and harsh skin, with mental and bodily energies sluggish and dull.

Oftenest, though, such children are precocious, clever, ready of apprehension, eager tempers, warm affections, lively, imaginative and susceptible.

Like other hereditary tendencies, it may skip two or three generations and re-appear just as family likenesses do.

The tendency may be so strong that nothing in the way of care will prevent its manifestation, or it may be so faint as to never break out dangerously if exciting causes be warded off—the most exciting causes are insufficient food, exposure to wet and cold, want of exercise, want of pure air, and mental disquietude. Climate exercises a very marked influence upon it.

Scrofula manifests itself in indolent glandular tumors, especially in the neck, lungs, ovaries, etc.—sometimes in the eyes or eyelids—the bones are also liable to disease, especially the bones of the spine.

Accidents of no consequence to others, produce serious trouble with these scrofulous constitutions.

All that can be done with any certainty of good results, is to keep up the tone of the system by careful attention to the air breathed, the food eaten and the clothing worn. Bathing, regular exercise, regular habits generally—are best. Iodine and cod liver oil are often used, but with doubtful results.—*Industrial Age.*

THE TREATMENT OF HYDROPHOBIA.—The French *Journal des Connaissance Medicales* relates that a man, forty-three years of age, having been bitten by a mad dog, was cauterized with a red hot iron four hours later. A month passed without any distressing symptoms, but at the end of that time he began to complain of epigastric and pharyngian constriction, and was very much cast down. Recourse was had to chloral at doses of about sixty grains, which succeded twice in affording a good night's rest; but the third time it remained without effect. The patient experienced great anguish; his voice was hoarse; he had tetanic contractions in the arms, neck, and breast, and expressed great fear, accompanied with hallucinations. In the morning he was utterly discouraged. They then administered sixty grains of bromide of potassium, which gave a quiet night, with a great improvement on the following day. Another dose of about seventy-five grains was given with equal success; all convulsive motions had disappeared. The medicine being suppressed, the convulsions began again a week later, when bromide was again administered to the amount of about ninety grains, which completed the cure. This remedy is readily tried, and we shall be glad to hear of any results that our readers can communicate.

TO PREVENT INCREASE OF CORPULENCY.—The *Phrenological Journal*, in answer to a correspondent, who inquires "What will keep one from growing too fat," says: "Sugar and fatty matter fatten those who eat them and can digest them. All the grains are fattening, and all animals that live on grain become fat if they have as much as they can eat. On the contrary, the animals which eat the flesh of other animals exclusively, never do become fat, no matter how much food they have at their disposal; but they do not feed on stall fattened beef, but catch game as it runs, and this is not fat enough to fatten the lion, tiger or eagle. Eat lean beef, mutton and fish, and avoid sugar, butter, and, especially, fine flour in all its forms, and eat but little breadstuff at all. Use tart fruit and common vegetables, and exercise freely."

A HINT.—Multitudes of women lose health, and even life, every year, by busying themselves until warm and weary, and then throwing themselves on a bed or sofa without covering, or in a room without a fire, or by removing their outer garments after a long walk, and changing their dress while still in a state of perspiration. If you have to walk and ride both, do the riding first, and, on returning, go to a warm room, and keep on all your wraps until your forehead is dry.

Domestic Economy.

Oat Meal for Children.

We see by an article in the *La France Medicale* that M. Dujardin has been experimenting with oat meal as a food for young children. He made use of a jelly prepared by soaking a tablespoonful of the meal in a glass of water for twelve hours, then straining through a sieve and boiling till the whole assumes the consistence of jelly, and adding sugar or salt to taste. According to analysis, 100 grammes of the meal contains 8.7 grammes of water, 7.5 of fatty matters, 62.5 of starch, 12.5 of nitrogenous matters, 1.5 of mineral substances, 7.6 of cellulose, dextrine and loss. Its nutritious value, therefore, as food for children, in regard to nitrogenous or plastic elements, and such as are respiratory, is analogous to that of human milk or cow's milk. Besides these it contains more iron than do most of the articles of food. Four newly born infants were fed with the preparation just described, and in every case with satisfactory results. In addition to its qualities as food it acts efficiently against colic and diarrhœa. It enters into the composition of the syrup of luther, which is said to be much used in Germany. M. Gillette, surgeon of the hospital of Melun, has also given oat meal, combined with cows milk, to six children, and finds it to be a valuable food in cases where the natural supply of milk is deficient.

A VERITABLE CURRY.—An Englishman who has traveled extensively, gives the following recipe for a curry he saw made in Malay, and vouches for its excellence: Cut up a fowl into small pieces, and provide four dried and two green onions, five chillies, half a teaspoonful of turmeric, one teaspoonful of coriander seed, one of white cummin, and one of sweet cummin. Pound the seeds, turmeric and chillies well, and slice the onions fine. Butter a saucepan, and, after slightly browning the onions, add the pounded ingredients, with just sufficient water to reduce them to a paste, and throw in the pieces of fowl, and mix well until the meat has a yellow tint. Lastly, add cocoanut milk and boil until sufficiently cooked. The cocoanut milk is obtained by soaking the finely scraped meat of an old nut in warm water, and straining out the fiber.

TREATMENT OF NEW WOODEN UTENSILS.—Wooden vessels for containing articles of food and wine, and wooden vessels for culinary purposes, can be rendered fit for immediate use by the removal of the unpleasant extractive matters, by treatment with a solution of washing soda. Thus an ordinary barrel should be half filled with water, and a solution of about two pounds of soda in as much water as will dissolve it; then head up the barrel and thoroughly mix the liquids by shaking the barrel, which should then be filled to the bung with water, and allowed to remain for twelve or fourteen days; then after withdrawing the discolored liquid, it should be well rinsed and filled with pure water and allowed to remain several days, when it will be fit for use. Other wooden vessels may be treated with a similar solution of soda.

COOKING GREENS.—Every housewife thinks she can cook "greens." It is the simplest of all dishes, and yet, in most cases, they are not well served, for much depends on the manner in which they are boiled. The water should be soft, and a tablespoonful of salt added to a large sized pot of it, which should be boiling hot when the greens are thrown in; and then it should be kept on the boiling gallop, but uncovered, until they are done, which can be told by their sinking to the bottom of the pot, and they should be skimmed out as quickly as possible into a colander, so that all the water will run out. Press them with a small plate, then turn upon a platter, add a large piece of butter and cut up fine. Serve while smoking hot.—*American Grocer.*

SUPERIORITY OF DUCKS' EGGS OVER HENS' EGGS.—The following details are given as the results of French experiments: An ordinary hen's egg weighing 60.4 grammes was found to have 7.2 gr. of shell and skin, and 53.7 gr. of contents, the latter, therefore, forming 88.07 per cent. of the whole weight. A duck's egg, weighing 59.8 grammes had 7.7 gr. of shell and skin, and 52.1 gr., or 87.12 per cent. of contents. Analysis of 100 grammes of the contents of hens' eggs gave 26.01 dry residue, 1.03 ash, 11.27 fatty matter in the form of sulphuret of carbon. An equal weight of the contents of ducks' eggs gave 28.89 dry residue, 1.16 ash, 15.49 fatty matter, showing that ducks' eggs contain a notably larger proportion of nutritive matter than hens' eggs.

MINCED FOWL—A FRENCH RECIPE.—Mince from the bones all the more delicate parts of the flesh of either cold, roast or boiled fowls; boil the bones, well bruised, in a pint of water until reduced half, then strain the gravy and let it cool; put it into a clean saucepan with a gill of cream, an ounce of butter well mixed with a dessert spoonful of flour, nutmeg and grated lemonpeel; keep stirred until it boils, then put in the fowl finely minced, with three or four hard boiled eggs, chopped fine, with pepper and salt to taste; stir in a squeeze of lemon juice; dish it with sippets of toasted bread, and serve immediately.

MINING AND SCIENTIFIC PRESS.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Concentrating Works at Falun in Sweden—Continued, 241-252. Latest from Panamint; Saving Gold from Sulphurets—"Rnsty Gold;" Pleaeant Talke About Inventions, 248. Metallurgy of the Copper-Silver Ores of Inyo County—No. 7, Macneale and Urban sates; The Great Pump Trial, 249. Patents and Inventions, 252.

ILLUSTRATIONS.—Plan of the Concentrating Work at Falun, 241. Dry Ore Concentration Works, 249.

MECHANICAL PROGRESS.—The Nature and Utilization of Slag; The Explosion Commmission; Depression in the Iron Interest Due to the Increasing Introduction of Steel; American Tools in Englang, 243.

SCIENTIFIC PROGRESS.—Molecules; A Shower of Hay; Collodion; A Water Shell; The Power of Ordinary Wind Eddies; An Experimental Aurora; Ballooning at Night—Observing Meteors, 243.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 244.

MINING SUMMARY from variouc counties in California and Nevada, 244-5.

USEFUL INFORMATION.—Trades of the Past; Toilers and Loiterers; Business Know-nothings; Action; The Idea of Pulverized Fuel not New; Diversities in Wood; When a House is not a Fixture; Jute Cultivation; Peanut Cultivation, 247.

GOOD HEALTH.—The Pain of Death; Invalid's Outlet; Dying from a Man's Bite; Bite in Nature's Cathartic; Scrofula; The Treatment of Hydrophobia; To Prevent Increase of Corpulency; A Hint, 247.

DOMESTIC ECONOMY.—Oat Meal for Children; A Veritable Curry; Treatment of New Wooden Utensils; Cooking Greens; Superiority of Ducks' Eggs Over Hens' Eggs; Minced Fowl—A French Recipe, 247.

MISCELLANEOUS.—Plants and Animals Found in the Human Mouth; New Safety Lamp; A New Substitute for a Barometer; Engineering Experiment; The Jnjuhe Tree; Restoration of Life After Freezing; Cerbonic Acid for Extinguiehing Fires; Utilizing Furnace Slag, 242. The Cryptograph; Kid Skins for Tanning; Potency of Sunehine; The Absorption of Water by Woody Fiber; Government and the Phylloxera; Centennial Co-Operation; How a Swarm of Bees is Suspended; The Voracity of Pickerel, 246.

Latest from Panamint.

Mr. Jacobs, the well known discoverer of the Panamint mines, is now in this city. We learn from him that there has been of late a decided improvement in mining results and indicationa in that district. Just before he left, hia company had taken out $7,400 in nine days' work with a five stamp mill—bullion 956 fine. The ore is free and easily worked—plenty in sight. The mill is now running regnlarly during the daytime.

The company of which Senator Jones is at the head, is also reported as doing well. They have already made a shipment of one ton of bullion and have another ton ready to ship. This company is rnnning a twenty atamp mill. The railroad is now within 150 miles of Panamint, and stages are running between that point and the end of the road every other day. Mr. Jacobs assnres us that the prospects there at this time are exceedingly hopeful; bnt he does not advise a rnsh of miners thither, although there is full employment for all who are there.

Giant Powder.—A fnrther explanation than that given in our issue of October 2d, concerning the suit of the Giant powder company vs the manufacturers of Hercules powder, seems necessary in order to give a full understanding of the effects of the decision, and we shall mention the subject further hereafter. In a late oirenlar the Giant powder company make the following significant assertion: "Onr powder is, and always has been, mannfactured nnder a distinct, independent patent, known as the Dynamite or Giant Powder patent—a patent having no connection with the two patents affected by the late docision."

A large cargo of lumber has been landed on the beach at Lompoc for the use of that colony.

Saving Gold From Sulphurets—"Rusty Gold."

At a meeting of the Microscopical Society of this city, held September 16th, a paper was read from Mr. Melville Attwood, nnder the above heading, which has attracted so much attention that we here reprodnce the same, with additional notes, specially furnished us by Mr. Attwood. The subject matter of this paper is of great importance to the quartz miner, and bids fair to work a complete revolution in the milling of quartz rock, and especially in the treatment of snlphurets.

"Rusty Gold."

Those who heve been for the past twenty-three years in any way connected with the California gold mines, will frequently have heard the complaints of minors and millmen that the gold of such and such a mine or claim was rusty, rebellious, coated with some snbstance that prevented it from amalgamating; that it floated on the snrface of the water and mercnry, and that they had tried all the different processes in use in the district, and that they could not by those methods save the gold. In speaking of their mines they said the rock contained so much free gold, besides that in the sulphurets, thereby inferring that the gold in pyritic matter was mineralized.

I heve good reason to know that in too many cases the fanlt arose, not from the imperfect mode of treatment, but that the rock really contained little or no gold to save.

Now, the fact is that gold occurs mineralized only by tellurium, that there is no ore of gold except the tellnride of gold and silver, which is found in such limited quantities as to be hardly deserving of notice, so that with that nnimportant exception all the gold met with in the different mines of California exists as a metal, and in that form is only mechanically combined with other minerals existing in exceedingly minute partioles, with the arsenical and iron pyrites, sulphide of zinc, etc., in consequence of which all these require to be stamped or reduced to a very fine state to liberate it. I trust by the aid of the microscope and these slides which I have prepared (as imperfectly as I nnderstend the nse of the instrument), to prove to you the fact of this mechanical combination, which is still regarded by many as an open question.

This is a most important thing for millmen to know, as it simplifies the treatment of the quartz rock, and shows, where it contains much pyritio matter, the absolnte necessity of fine stamping.

I have for the last forty years been more or less practically engaged in mining and milling for gold, and during that time seen processes too numerons to mention tried to save the gold, from the most primitive down to what is nsed at the present time; also, the plan of roasting the vein matter, and the chlorination process for the sulphurets or pyritic matter, and oen now fully realize what time and money might have heen saved had a mioroscopic examination been made of the vein matter under treatment by the different processes. In answer to the complaint of the miner and millmen

A Microscopic Inspection Would Have Revealed

To them that there was no such thing as rusty gold, and that the float was only laminated gold, caused by the action of the stamps, or from other causes, and in that state exposing a great amonnt of surface in proportion to its weight, and that the pyritio matter had only to be reduced or stamped to an exceedingly fine state to free the gold encased in it, which would then amalgamate with the same facility as the rest of the gold in the quertz. If an examination had been made of the roasted veinstone, it would have been found that a large portion of the gold by that process was in a manner really coated or enveloped in a slag, and thereby partially rendered unfit for amalgamation; I refer to what is called roasting in heaps.

Description of Slides.

No. 1. Monnted on this slide is a specimen showing gold mechanically combined with prismatic iron pyrites. I selected it not only for its great beauty, but that a careful examination of it will snpport what I have stated in reference to the mechanical mixtnre of the gold with the pyritic matter.

No. 2. Section of veinstone from a mine near Nevada City—gold in mechanical combination with arsenical pyrites and zino blende. The gold can be easily distinguished encased in the pyrites. I have used a two-inch objective, but if examined with a higher power it will show the minuteness of some of the particles of gold.

No. 3. Gold in mechanical combination with the telluride of gold and silver.

No. 4. A beautiful speoimen of the tellnride of gold and silver, and gold.

No. 5. The telluride of gold and silver, and gold in a leaf form, or feldspar.

No. 6. Gold in jacotinga (micaceons specular iron ore) from Gongo Coco mine, Brazil. In Brazil veins of jacotinga yield large qnantities of gold. Veins of thet charaoter have not yet been found in California. The speoimen from which this was broken waa taken from the mine in 1832. The yield of gold for six months in that year was 2,371 pounds, Troy.

No. 7. Gold in talo.

No. 8. Gold in talc.

No. 9. Gold in rock, after roasting in heaps.

No. 10. Section of veinstone from the Sumner mine, Kern, with zinc blende and arsenical pyrites.

No. 11. Gold from the Sumner mine, showing the minute metallic particles in which it oconrs in the sulphuretted matter, and the necessity of fine stamping in order to liberate it. To treat it properly, the rock or vein stone ought to be stamped fine enough so as to pass through a sieve having 10,000 holes to the aqnere inch.

No. 12. Float gold, from gold sands found on the south beach, at the entrance of Humboldt bay.

No. 13. Beach gold, and gold from the pyritio matter, mounted together to show how much larger the particles are from the beach gold.

No. 14. Placer gold having the appearance of being rusty.

Before concluding I wish to make a few remarks respecting the milling of gold-bearing rock, and though it may not be exactly what should be brought before our Society, yet being done for the parpose of interesting the millmen, so thet it may indnce them to avail themselves of the use of the microscope in their works, and my endeavor to show the importence of the microscope to any one engaged in milling or mining must plead my excuse, if any be required.

For a number of years at the St. Johu dal Rey mine, Brazil, they have obtained all their gold from the concentrated pyritic matter, (here called sulphurets) by simple amalgamation in barrels. The concentrated stuff or sulphurets, which is a mixture of arsenical, common, and magnetio iron pyrites, is also termed in California *rebellious ore*. Mr. Dietzsch in his report to the company in 1867, says:

"Onr actnal process of amalgamating the sand is under ordinary circumstances sufficiently complete. Fifty pounds of ordinary mercury combine with thirty-six to forty ounces of gold dust disseminated in sixteen cubic feet of pyritio sand (sulphurets) free from decompesition, in the rotating barrels dnring twenty-four to twenty-six honrs, leaving in the residue little more than half an ounce nf the gold contents, part of which, being still in mechanical combination with the send, is afterwerds extracted by a further grinding in the arrastras."

By Mr. Dietzsch's report it appears that the actual loss of gold in the amalgamation of their snlphurets in barrels does not amonnt to one per cent.

In the same report it states that the stamps in that year reduced 60,685 tons of veinstone, and the quantity of snlphurets amalgamated was about 3,891 tons. The loss of mercnry 1,461 pounds, or at the rate of a little more than six ounces to the ton of sulphnrets. The cost per ton of the veinstone treated was four shillings and sixpence half-penny.

The St. John del Rey veinstone, when it is called pure, may be taken at forty-three of silica, and fifty-seven per cent. of pyritous matter. Of these minerals arsenical pyrites is nsually the most anriferous. Gold is rarely seen previous to concentration in any of the veinstone from thie mine.*

By the Washoe pen process, the waste of mercnry in the working of the Comstock silver ore, and argentiferons gold, amounts to nearly three times that of the St. John del Rey, notwithstanding that the mineralized silver treated in the pan mills scarcely ever reaches to more than two per cent.

It may not be known to many, yet it is nevertheless a fact, that the milling of any of the rich gold veinstone of Californie, excepting those holding the tellurides, even if it contain 80 per cent. of pyritic matter, may be accomplished with a loss of under four per cent. of the gold conteuts of the veinatone, by the simple process of dry stamping and amalgamation in barrels, and with a loss of under fifteen per cent. by the Washoe process of wet atemping and amalgamation of the pnlp in pans—without chemicals even when the gold contents of the veinstone is nnder $10 per ton. Low grade veinstone will not, hnwever, hear the expense of dry stamping and barrel amalgamation, or even the Washoe process.

I believe when fairly tested that the nse of chemioals in the treatment of a large portion of the Washoe silver orea will be fonnd to be as great a mistake aa that of allowing (aa they now do in aome of the large new mills) the pans to do the work of the stampe. In other words, that the Washoe mills would get through more ore and obtain larger resnlts by finer stamping and naing little or no chemicals in their milling operations. The loea in working low grade gold rock in Australia, from the published reports of the different mining companies, averages about twenty per cent. on eight or a ten dollar rock. What is done at onr California gold miues I am unable to say, ae in their reports they do not give either the gold contents or loss on treatment. I am inclined to think that no check is kept of their workings. In Australia they appear to work to a profit a lower grade of rock than is done in California.

*Mr. Attwood has placed in our possession some small samplee, which are said to be a fair average of the character of the veinstone raised from this mine dnring the year 1867, which can be inspected by any person interested in this paper, or in the extraordinary results of the milling process at the San Juan del Rey.

The owners of the Livermore coal mine have just bought a new engine and tested it and pnt it at work. It is worth about $8,000 and will prove very efficient in hauling up coal.

The Bakersfield presa are agitating the snbject of building a road direct from that town to the coast *via* San Luis Obiapo.

Pleasant Talks About Inventions.

No. 3.

In the seventeenth century steam and steam engines reached a high development and became the great power of the world. A new impetus was given to commerce, the arts and industry, which created a vast demand for labor-saving mechinery of all kinds. Heretofore, as a rnle, inventions or discoveries were accidental or the resnlt of the necessity which suggested them. Now inventors begen to assume the rank of a profession, and at the present day tens of thousands of great and smell inventions attest their skill and deep research.

Balloons were invented by Gnsmao, a Jesnit, in 1729. They were not brought before the public for some years after, and then by the Montgolfier brothers, of France. Aerial navigation, ever since its first success, has been made the subject of acientific and laborious research and experiment, and as yet the problem remains unsolved. As far as practical navigation is concerned the balloon of to-day is nnder no better control than the first tiny air ship thet sped upward to the nnknown region beyond. Franklin bottled lightning in 1748, and his daring experiments led to the triumph of thet science. The next important invention was that of the spinning jenny, in 1759, over 400 years after the invention of the spinning wheel. It was named after the wife of the inventor, an honor hardly deserved, for she was a reguler termagant and led her hnshand a terrible life, and finally kicked him and his model out doors. It took him weary months to repair the damages resulting from her causeless fit of anger. It was done, however, and the genins and patience of the hnmble mill-hand rewarded by the greatest labor-saving machine of the age.

The cotton gin, a machine that made cotton king, and developed the resources of the Sonth as no other one discovery haa since the settlement nf the country, was invented by Eli Whitney, in 1793. Whitney wes a school teacher and the idea was suggested to him by a Southern lady, at whose house he was stopping. Lithography was discovered in 1796-8 at Munich by one Aloys Senefelder. The most important discovery of the century was that of galvanism in 1786. Thia great science is, and will ever be, of inestimable benefit to the human family.

As an indication of the primeval manner of the early gastronomists, it will be noted with interest that forks were invented in Italy, and introdnced into England, in the seventeenth centnry. The table and its auxiliaries have been very greatly improved since accnbation was considered quite the thing by the ancients, who lifted their food with their fingers and were satisfied. Or even onr own worthy ancestors, who gathered abont tha well-filled tureen of swimming fat pork and gravy and "sopped" ont their fill, meanwhile passing aronnd the hnge chunk of maple sugar snspended over the table, biting off a due qnantity to sweeten each sip of their fragrant Bohea. Such proceedings in this dey of finger bowls, napkins, etc., would be apt to disgust the fastidions.

To enumerate the inventions of the present centnry wonld be a hercnlean task. Of their magnitude and practical benefits, we have ample evidence on our oceans and rivers, in our workshops and mannfactories, in the chambers of art and the halls of science, in the miles of iron and steel rails that diverge to the nttermost limits of civilization, and in the transmission of intelligence by the network of electrio wires that encompasa the entire world.

One of the most important inventions of this century, is that of locomotive engina in 1804. In 1820-40 mechanics' institutes made an appearance and rapidly spread over Europe and America. The greatest invention of the age is, beyond cavil, the electric telegraph, olaimed by Morse, as his inventioo, in 1832. It was not developed and introduced nntil some years later. Thia invention is also claimed by Cooke and Wheatstone, of England, they having patented their system in June 19th, 1837, while letters patent were nnt obtained by Morse until September 27th, 1837, a diff rence of nearly three months in favor of the Englishmen. It is and probably will remain a vexed qnestion as to whom the honor is due, although public opinion throughont the world generally sustains Morse in his claim. Daguerreotypes, named after the inventor, were the product of 1839. Another experimenter claims that he communicated the discovery of photography to the French Academy of Science at an earlier date. As Daguerre was several years perfecting his snn pictures before he brought them to the notice of the world, there is no doubt bnt that he is entitled to the honor of the invention. Gnn cotton belongs to the year 1846, and nitro-glycerine followed in 1847. A minor invention, but one of wide spread nsefulness, is that of steel pens, in 1803. Before that time, he who wonld write had to depend npon his gray goose quill. An innovation was attempted late in the seventeenth century, by the introduction of tortoise shell pens, tipped with gold. They were not a snccess.

The entire world is now anxiously awaiting the development of the Keeley motor. If it sustains all that is claimed for it by its inventor, its advent will completely revolutionize mechanica and trade. It will be a power beyond calculation. The stories told of its capacity are so fabulous that thinking men are apt to doubt their reliability. A few months will determine, however, whether the Keeley motor is a myth or the acme of invention. M. J. K.

Metallurgy of the Copper-Silver Ores of Inyo County—No. 7.

[Written by Samuel Purnell.]

Concentration.

The devices for wet concentration heve been and are now almost endless. The curious reader, hy refsrence to works on this subject, will find that ores have been attempted to be concentrated hy an almost infinite variety of machines, and that in many oasee they were hased on principles exactly opposite to each other. Among the latest water oancentrators, aspiring to popular favor, ere thó Cazin, the Utsch end the Frue automatic jigs. Thet they will do good work nn a certain class of orcs oannot be douhted; hnt it is not probable, iudeed herdly possiblo, for them to concentrato a glanco or fehl ore (such ae those of Inyo oounty) with profit. Soldom have the most approved wet coucentratore heretofore been able to hendle oree of this description at a less lose than 40 per cent.; and from the nature of the subject, it seems likely that this proportion of loss cannot be lessened. In Earope, where centuries of skill have heen hestowed upon silver ore oancentration, it is considered iu a high degree of perfection when only 15 per cent. of silver is loet. The preeence of lime, clay, etc., may ran the losses up to 80 or 90 per cent., thus rendering concentration impossible. It is common for the ownere of patent water jigs to claim much lower losees than thie, with their perticular devicee—they are generally eelf-deceived. But when the buyer attempte to oancentrate his fahl oree with them he ie lucky if he escapes with eo emell a loss as 40 per cent. Could such ores he profitehly concentrated by water jigs, every mining camp, in which these minerals occur, in California, woald have them in operation; but as far as the observation of the writer goee, there is not one eteadily at work in the State. The expense of erecting a oomplete water dressing works ie high. At Mine La Motte it ie reported thet a complete wet dressing works, on the plans of Rittinger, were srected a few years ago, at a ooet of $300,000, but after a succession of failures they were abaadoned. Silver slimes will alwaye he lost in tailings and waste water.

The result of an examination into the subject of water concentration for the fehl oree of Inyo county, leads to the ooncluaion that they are ill adapted to the process, and that experimente in that direction must end in failure. Were there no other known method to concentrate thees silver oree economically, then concentration might be said to be practically impoesible. It ie fortuaate that a dry air jig hae lately heen perfected, which seems better adapted to these orea than any wet procese yet devised. Ae it is oonsidered to he an important contribution to Americen metallurgy, some space will be devoted to ite explenation.

Krom's Air Jig.

Concentration by an air jig wae first introduced into Germany, by Aafermann, some thirty yeers ago. The first triele did not prove eatisfactory, owing to the crudity of the apparatue employed. The growth of an importaat invention is the slow process of years, and eeoh saccessive inveator adds to its completeness. (Fig. 8.) Under the hande of Mr. Krom, the dry eir jig has now become an almost perfect device. The dry ore in powder and coarse grains is subjeoted to eudden puffs of air from helow, through a grete. The ore ie automatically supplied upon a horizontal sieve, and the concentrated portion is discharged upon one side and the tailinge upon the other. The principle is besed upon the agitation of the ore, hy meens of jets of air rapidly applied. The machine is valuehle in concentrating nearly all minerals—even though in some special caese water oancentration may also be practicehle—but it will also concentrate, with profit, clasese of oree wholly uamanageable hy eny wet process. Especially is this true of complex silver. This was proved by experience in Nevade, Utah, Colorado, and various Eestern states. So euccessful have thees air jigs proved, when operated hy skillful men, that it ie thought by those familiar with the subject that they will in time nearly displece all water jigsin the separation of complex ores. It is difficult to imagine a machine doing ite work more satisfactorily. That there is considerable prejudice against air concentration ie well known, but it will be found that this prejudice is not among those who are heet informed on the snbject, but among those who refuse to be inetructed, and will not believe that anything whatever oen be adopted that ie superior to water for dressing oree.

For some of the facte and argaments which follow, iadebtedness ie acknowledged to some letters by G. W. Baker, of Colorado. The argamente most readily used against the air system have been mainly those cited—experimentel failures, theories and eystems in Europe wherein air, as the medium, failed to sustain the merits claimed for it by inventors and experimenters. But thie kind of argument will apply to the water eystem just as well, or indeed to anything elee. The use of water jigs hae never produced results as good as those of air. It is aesumed that the perfection of water dressing is found in the modern water jigs, in which the principle is eimply submitting the ore to the action of intermittent impulses, suddenly lifting the body of ors to he operated upon, and then allowing free sahsidance of the particles, so that each may as nearly as possihls fall according to its specific gravity. In like manner, the perfection of air dressing ie found in a like intermittent action, euddenly lifting the body of nre to he acted upon; subsidence here allowing each atom to act on ite own gravitating laws. Experiment has proved that the number of impulses to be given hy or to water oannot exceed 100 per minute, if more frequent there ie no subsidsnce. In the use of air, 400 impulsee may be given por minute, without destroying the principle of impulses and subsidence. This is due to the fact tbnt hodies fall much more rapidly in air than in water. Therefore, on the quantity separated of light from heavy, the proportion will he as one to four in time. In the water jig, the samo fluid which oausee tho upwerd impulse stays with and must accompany the ore to he discarded as tailings, and so far as the separation is not perfect, there is no remedy against the flowing awey of valuable meterial. If thie were the fact with air it would he apparent that nnder liko circumstancee eir would oarry off loss valuahls materiel than water, inaemuch as air is very much lighter than water. But in the case of air the medium or fluid which oauses the upward impulse does not etay with or accompeny the ore to be discerded ae tailings. Air does its work and leaves, mingling with the etmosphore, and the only flow is thet of tailings. The amount of dust carried away from the machine is easily recovered hy a suitable dust chamber. It can be drewn away hy exhanst fans. A denser medium must cerry off more dust or slimes, which will contain more veluable matter as its specifio gravity is greater. Hence, if the flow of air and weter were the same, the former would carry off less than the latter; but in air, the ore particlee have lese interference than in water, and results are obtained by the use of air which are scarcely possible with water. Soms advocatee of water dressing have considered that even a denser medium than water would he adviseble, and that it would effect a closer separation; but it would seem that these partice must reaeon from mistaken notions of the nature of ore concentration; the facts being exactly opposed to their reasoning. Sizing the ore graiue is less essentiel in eir than in water dressing, elthough proper sizing ehould never be omitted in any system.

The eir jigs are automatio in their action, requiring no aseistaace or attention. In arranging a dry concentrating worke, it is ueual to so place the machinery that the ore ie untouched by hand from tbe time it is fed into the rock breaker till the concentrates are sacked. Tailings may be discharged into a stream of water and carried away; they seldom contain minerel enoagh to pay for reooncentration. The tailings do not, and need not, usually assay more than from $3 to $5 per ton. The extent to which the concentration may he carried will vary locally for each ore. It ie possible to obtein tailings almost entirely harren, if so desired. The rates of ore to concentretes must aleo continaally vary. In some cases the concentration of five tone into oae may be a suitehle proposition, while in other oaees thirty tons have heen concentrated into oae with advantage. No rules can be laid down in advance for this; it is only experiment on each ore that will decide the question. (Fig. 9.) A complete mill, for air oancentration, with a capacity of 30 to 40 tone a day, will embrace a suitahle building on the hill eide; a rock breaker; two eets of steel crushing rolls, one coarse, the other fiae; a eet of riddlea to eize the ore; an elevator; an exhaust fan; half a dozen air jigs; a dry floor; power, aud euitable bine for holding the concentrates. Erected in California, euch a mill will cost ahout $40,000.

For a better underetaading of the accompanying engraving, we give the following explanation of the figures appearing on the face of the plan: *A*, ore; *B*, Blake crasher; *C*, drying cylinder; *D*, engine; *E*, screws; *F*, crnshing rolls; *G*, elevator; *H*, dust exhanst fan; *I*, dast chamber; *K*, bins for sized ore; *L*, air concentrators; *M*, sluice for tailings.

The number of men required in the oancentration proper is smell, one to look after the machinery, one to feed the rock breaker, and another to remove the concentrates. The complete cost of treatment, from first to last, nnt including losses, amounts to about $5 per ton. Almost the entire loss is in the tailings. The dust from the rollers and screens, collected from the dust chamber, may uadergo a special concentration, or it may be worked for its silver direct. From an air concentration mill erected in Star canon, Neveda, it is reported that everything worka admirably. Tho nrss are similar to ths fahl ores of Inyo oounty, and substantially the same manipulatione would he necessary with ths latter. The Star oanon mill, unfortanetsly, has not been ahle to run regularly for want of a supply of ores from the mines. From one lot of 700 tons, the assay valae of which was $54.56 per ton, the concentrations were valued at $1,660 per ton, and the tailings $3.47. Tho entire cost of separation wae about $5 per ton. The most approved methods of water coucentration had been tried on these oree and had proved a failare, as the losses in silver amounted to 75 per cent., end the resalting 25 per cent. was not sufficient to leave any profit. By the eir jigs, 95 per cent. of the silver was saved, e result wholly unattainahle by any system of water dressing. The cost of an air jig is eome $500, and the capacity is about helf a ton of ore per hour, with an expenditure of one-eighth-horse power.

All clnsees and varieties of orss, from every part of the country, have been eeperated hy these mechines with satisfactory resalts. The character of the medium of separation, the delicecy and precision of operation of the machinery employed, renders ooncentretion posible

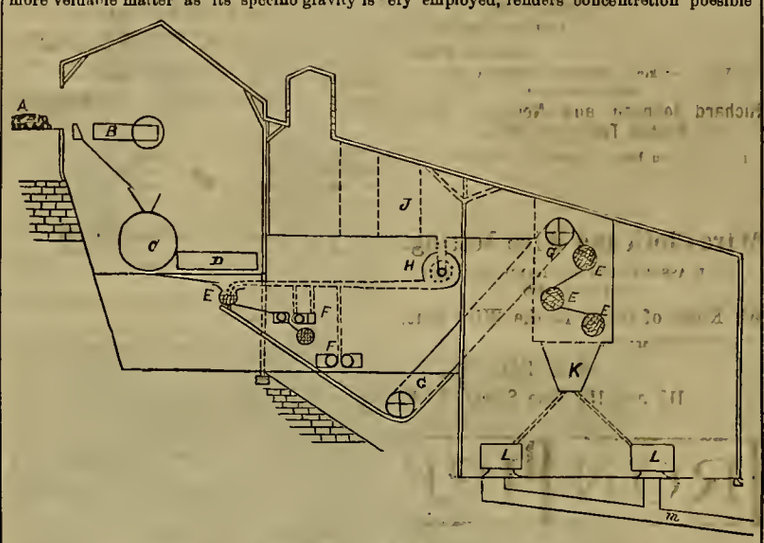

Fig. 9. DRY ORE CONCENTRATION WORKS.

end practicable with all eubstances which have a difference of specifio gravity of only one per cent. This hes been done by the Pennsylvania ealt company in the separation of cryolite from epathic iron ore, on whioh water jigs had failed. The separation of blende from galena ie aleo eeeily effected.

It would seem from the experience of intelligent and competent parties, who have worked air jigs on ores most diffioalt of concentration, and on thoee similar in constitution to the ores of Inyo coanty, that the introduction of thie machine in thet county (and elsewhere) would prove a oomplete success; at leaet, no reason is known to the contrary. The cost of a oomplete mill is a formidable item, but it should be remembered that a complete wet concentration worke cenaot he erected for any less eum, and the result would not really be so profitable. It is, of course, possible to concentrate ores, hy both the wet and dry syetems, entirely by hand. The expense of this would prevent its adoption on an economical scale. Whatever advantage there may be between the two systems, as regards ooet of machinery, will rest on the side of the air system.

In conclusion, it would seem probable that a proper application of the metallurgical processes, only briefly expleined in the preceding pagee, would reise the mining industry of this county from its present languishing condition. And the same may be said of other districts, where the ores are similar. It is almost neeless to depend on the amalgamation procese, and keep looking for a chemical to neutralize the base metals. It was never found in Europe aad never will he here. The orude amalgamation process should be diecarded in the workiag of these ores. However well it may operate on what is called "free milling ores," it will never work profitably on what is called "rehellious ores." The object of this paper has been to point out better methods which are within the reach of all. It must eventually come to this, that these improved methode muet he introdaced or the working of these oree must be abandoned. Capital will not go on forever losiug itself in useless amnlgamation mills, which are soon closed ee failares. The melaucholy wrecks strewn all over California and Nevada are sufficient evideoce of whet the general resalt will be. The abandonment of a crude process and the adoption of these modern scientific methods is a necessity of the day. The longer it is delayed, hecause of the general unwillingness to learu eny thing nsw, the worss it will he for minera and mining capital. Thess nsw processes mnst be adopted soonsr or later, and those sagacious enough to first put them in practice will reap the greatest harvest. Their general adoption can be only a question of time.

Macneale and Urban Safes.

George A. Raymond, No. 121 California street, makes a very neat display of the Macneale & Urban firs and burglar-proof safes, vaults, locks, eto. A prominent fsature in the exhibit is a No. 20 safs of this meke, which went through a very fierce fire when the town of Tularo was hurued thie yeer. The aafe fell iuto the cellar of the stors, and upon it fell the hurning timbers of the building and several tons of flour and suger. Flour and sugar iu burning creete a very intense hoat, and yet after ten hours of this severe test, the booke of Sieeon, Wallece & Co., ths ownere, were found in perfect condition. Ou account of the inside bolt work, the eefe wae opened without the leest difficulty, hy means of the lock. The battle scerred veteran now attracts oonsiderable attention. The inside is somewhat stained by a quantity of opium which wes placed in the sate at the time of the firo, but otherwise it was uninjured inside, even in appearance.

The peculiar constraction of theee safes affords entire security against burglers. The doore are rebated and provided with tonghe and groove joint extending entirely around them. This joint is accuretely fitted eo thet no explosivee can he introduced, and wedging ie rendered abeolutely impossible. The metal ie "Malacent steel." The menner of fastening ths plates together with reverse thread, conical holts, ontside eteel surfaoee, solid corners, double tongue aad grooved doore, rebated edges fitted so closely, makes the safes impregnable. The perfect workmanship, ground jointe and close fitting all around, with the smooth-working locks, square shoulders, spindles and detachable bolt work, make the large vaults a first clasa protection againet fire or thieves.

All of these safee bave triple flange doore, seven inches thick, with the petent inside holt work. The bolts and looks ere placed inside of the fire-proof material, and thereby protected from injury by fire, while in many other makee of sefes, it ie foand necessary to cut them open after paesing through a fire, in order to gain access to their contente. On examining the safe it will be seen that the hinged cep of door being thrown open, expoese the bolt work and lock to view, placed on the inside of the filling or concrete instead of on the outside, or next to the outer plate of door, ee is ths case in other eafes. The value of this device must be pateat to every one.

The Great Pump Trial.

Probebly there wes no exhibition at the late fair of the Mechanics' Institute of more general interest to both mining and sciontific men than that of steem pumps. It had been arranged that the trials of the severel pumps entered for competition ehould take place during the lest days of the fair. It was not, however, until Friday, the 8th inst., that preparations had heen sufficiently completed to allow of the commencement of the trial. Four pumpe hed been entered for a competitive trial, viz: The Bleke, entered hy H. P. Gregory; the Knowles, entered by A. L. Fish & Co.; the Hooker, entered by W. T. Garratt, and the Wilcox, entered hy W. C. Wilcox & Co. It wae arranged that a day should be allowed for each pump, and each ehould use the amount of steam they deemed fit. The following geutlemen were selected as the committee on these trials: George H. Dickey, of the Risdon iron works, chairman; Mr. Fish, of the Delamater iron worka, New York, and Mr. Detrick, of the Union iron worke. When the triel took plece it was fouud that the Blake and Knowles pumps each used an eight inch steam end an eight inch water cylinder; the Hooker pump ased an eight inch steem and five inch water cylinder, and the Wilcox ased an eight inch steem and a six inch water cylinder. The amount of steam in the test wae, in the Hooker pump, 25 lbs., the Blake, 45 lbs., and the Knowles and the Wilcox 70 lbs. each.

The result ot the triel wae so nnsatiefactory that the committee, after consaltation with the parties interested, resolved on heving a second test, which will take place in ahout ten days' time, when each of the co nteetante will task their pumps under en equal steam pressure of 60 lbs., and with an eight-inch steam and eight-iach water cylinder. It will be required to force 15,000 gallons of water through an upright pipe 58 feet in hight, one day being allowed to the trial of each pump.

The Scientific Press will have a representative present, and, in the issue fol'owing the trial, a full report will be spread hefore our readers.

There are ten saw mills between Healdsharg and the mouth of the Ruseian river. They are cutting in the aggregate eighteen million feet of lumher per year.

The grading on the Woodland and Tehama branch railroad has been finished a distance of about fourteen miles.

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR APPLICATION—requiring no thinner or dryer, and will not spoil by standing any length of time.

It is Cheaper, more durable, more Elastic, and produces a more Beautiful Finish than the best of any other Paint.

It will not Fade, Chalk, Crack, or Peel off, and will last twice as long as any other Paint.

In ordering White, state whether for Outside or Inside use, as we manufacture an Inside White (Flat), for inside use, which will not turn yellow, and produces a finish superior to any other White known.

Put up in ¼, ½, 1, 2 and 5 gallon packages, and in Barrels. Sold by the Gallon.

For further information send for Sample Card and Price List, or apply to the office.

THE TURBINE.

Simplest, Cheapest, and Most Durable.

The Inventor of the Dexter Windmill has made new and useful improvements in Windmills, patented March 16th, 1875, and now feels confident of having the SIMPLEST, CHEAPEST, MOST DURABLE, and

ONLY PERMANENT WINDMILL

IN THE WORLD.

SIMPLEST, because it is less complicated; CHEAPEST, because it never needs repair, standing on a firm foundation; MOST DURABLE, because it is all under cover, and has less rigging to get out of order; ONLY PERMANENT, because the only Windmill in the world that has never been injured by storms. Hundreds of people, who have thought the Dexter perfect, will be glad to observe the SUPERIORITY OF THE TURBINE over all predecessors. Although much improved, the price of mills remain the same as formerly. Persons who study their own interest will investigate the TURBINE before purchasing any other.

Territory for sale outside of California, at reasonable rates and easy terms.

Mills built to order of the best material, and at the shortest notice, by Kimball Manufacturing Company, corner Fourth and Bryant streets, San Francisco. Any orders sent to their address will receive prompt attention.

SAVE YOUR HORSE'S FEET!

NO MORE RASPING AND HAMMERING TO CLINCH HORSE SHOE NAILS. TENDER FOOTED HORSES SHOD WITH EASE. EVERY TEAMSTER HIS OWN BLACKSMITH.

The new patent implement used is an attachment to an ordinary pair of pincers. A scoop-shaped graver, or chisel, and a flattened, roughened plate, (formed in one piece) are hinged and fastened on to the handle of the pincers. When the forceps are closed the graver projects from one side of the handle, and is retained in that position by allowing the end of the plate to enter a slot between another plate on the other handle, and the handle, thus holding the graver steadily, while the forceps are grasped by both hands, and the groves cut in the hoof below the point where the nails come through. When the groves are cut the handles are opened, and the roughened plate turned outward, thus carrying the graver into a slot in the socket, out of the way.

To clinch the nails after the grooves are cut, the handles are opened, and the roughened plate is put beneath the hoof. The edge of a steel plate on the handle of the forceps is then placed above the nail point, and by closing the handles the nail will be bent down into the groove already cut, where it lies nearly flush with the hoof. The plate can be adjusted for large or small hoofs. The groove cut by the graver is about one-eighth of an inch long and one-eighth of an inch wide. No hammering or rasping is necessary. The foot is not bruised or scarred. Any one can learn to use it in a few minutes. Tender-footed horses can be shod with no pain to them. Further information given, if desired, by CHARLES DONNER, Inventor, or C. F. SUHL, Cor. Commercial & Drumm Sts., S. F. eowbp

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.

It is unequalled for cleansing Woolen Fabrics, Cutlery, Carpets, Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing.

It renders water soft, and imparts a delightful sense of coolness after washing.

DIRECTIONS.—For Laundry, use two to four tablespoonfuls to a washtub of water. For bathing, use one tablespoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterward. For stimulating the growth of plants, use a few drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.

Also, SULPHATE OF AMMONIA for chemical purpose, fertilizing, and the preparation of artificial manures. AMMONIACAL PREPARATION, for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing, and PURE LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes.

☞ Manufactured by the

All orders promptly filled.

MOREY & SPERRY,

88 Liberty street, N. Y.

Examination solicited.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 60 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

54 BUSHELS OF CORN AN HOUR.

HARRISON'S LIGHT, VERTICAL BURR MILLS

BARBER & BACON, MILLERS AND LUMBER DEALERS, SOUTH VERNON, VT., write July 15th: "We have been running two of your LIGHT VERTICAL CORN MILLS for the past 6 months with remarkable results, and have ground over 80,000 bushels of corn into No. 1 meal in that time, running the grist-mill nights only, as we run our saw-mill in the day time. We have often ground in the 26-inch Mill (which weighs about 240 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 24,300 lbs., or 434 bushels. To do this we have to run at a speed of 1,300 turns per minute, and use about a 20-horse power. You may refer parties to us for further information, and when we have tested your HEAVY VERTICAL MILL, we shall take great pleasure in giving the results."

(Continued from Page 241.)

class of *jigstuff*, which is discharged out of its largs end into receptacles, and from these feeds directly into its reepective jigger, and sifts off screenings, which pass on to the next sieve drum. To this end the lower half of the drum is surrounded by a cast iron mantle, having a spout at its lowest end, through which the discharge of the pulp into the next drum takes its course.

To save space and fall, the drums are laid with receiving and discharge end alternating, so that the pulp follows a serpentine course in passing through the apparatus.

Designating the products of the drum by the diameter of the openings in the several screens, the apparatus *a* 4 yields *coarse gravel* of 22, 16, 11.3, 8 and 5 mm., and the screenings of the fifth drum, which are lifted to the top drum of apparatus *a* 5.

This latter yields *grit* of 4, 2.8, 2 and 1.4 mm., moreover, one mm. *sand*, and the screenings of the fifth drum, which, passing through the 0.7 mm. openings into the sluice, *a* 8, run finally into the *funnel apparatus*, *a* 9, for condensation. From here it is lifted by the cup elevator, *d* 6, into the V tanks, in which, and in the following *funnel tanks* it is *graded*.

In order to avoid lifting the whole pulp—which would not only require much power, but would also deteriorate the classing work of the drums, on account of the great current of water in that case passing through them—part of the water is run out of the top of the elevator hasins into several reservoirs, placed below the floor of the building, in which the sand and slum contained therein can settle. From time to time this is shoveled back into the elevator basin, *a* 7.

Two workmen are engaged in the transportation of pick stuff, and one man tends to seven automatic continuous jiggers.

The work of the jigger will be described further on.

IV.—The Crushing of the Coarse Rock, or "Knockings," With the Rock Breaker.

The large pieces of ore, (Engl. knockings,) hoisted from the mine, are subjected, in the immediate vicinity of the shafts, to a rough sorting, by spalling them down to six or eight inch pieces, and pickings.

The products from this work are:

1. *Piece ore* (specimens,) which go directly to the smelter; and

2. Waste rock, or *deads*, which are thrown on the dump.

3. The rest is carried by railroad into the dressing works and dumped into hoppers placed above two rock breakers or "crushers."

The bottom of the hoppers has a considerable inclination toward the mouth of the crushers, which facilitates the feeding, it being attended to by one laborer without much exertion.

The upper breadth of the mouth of the crusher is sixteen inches, the lower nineteen inches, the width ten inches on top, and varying below as fine or coarse crushing requires; usually it is one and one-fourth inch, enlarging three-eighth of an inch at each stroke. The shaft makes from 200 to 250 revolutions per minute. It has been found advantageous to lubricate the bearings of these machines with oil and water alternately, their heating being thereby entirely avoided.

The construction of the crushers does not vary materially from those in use in Germany. From the Blake's crusher they differ in several details: the inclining of the jaw-plates downward, and the absence of corrugations on them, (being made preferably of late of wrought iron;) the absence of the power lever, and many differences in other details of construction.

Each crusher will break up three and a half to four tons of knockings of six to eight inches, down to pieces about one and one-fourth, to one and three-fourth inches in size per hour.

Below each of the crushers, *b* 1 and *b* 2, is a cleansing or washing drum, *b* 3, and a rotating sorting table. These tables are the same as above described. The cleaning drums however, are somewhat smaller, otherwise the same as those used in the rubbish work. The openings in the screen are twenty-two mm in diameter. The drums also make eighteen revolutions per minute.

The crushed ore falls from the breaker directly into the wash drum, and the material retained by this—the pick stuff—discharges from its front end on to the sorting table. The hopper surrounding the latter is constructed as before described in the rubbish works.

The products of this sorting are:

1. Piece ore, first quality, with fifteen to twenty-two per cent. copper.

2. Piece-ore, second quality, with six to ten per cent. copper, both ready for the smelter.

3. Crush-stuff for the Cornish rollers.

4. Stamp-stuff—poor ore, with finely disseminated copper pyrites.

5. Barren rock or deads, in proportionately small quantity, as they have already been separated as much as possible in the *rough sorting*.

The stamp-stuff, being the greatest mass, remains on the table, and is scraped off into its compartment in the hopper, all other sorts having been picked off by hand, as before described.

The assorted stuff falls out of the five compartments of the hopper into care placed beneath, is carried in these and on the elevator up to the garret floor, and thence to its respective destination.

The screenings of the clearing drums are *classed* in the two sieve drum apparatus, *b* 5 and *b* 6, which are counterparts of those above described, *a* 4 and *a* 5. The screenings-pulp firstly goes to the elevator, *b* 7, is raised by this into the topmost sieve drum of apparatus, *b* 5, passes this, as also the four following, and, the five sizes or classes of *gravel* being thus separated and given to the jiggers, the siftings of the fifth drum are raised by the elevator, *b* 8, into the top drum of apparatus, *b* 6, and the finer classes following are separated, etc.

The number and size of the several products thus obtained, are the same as enumerated in the classing of the rubbish work, and the further operations to which they are subjected the same as there designated. Here, however, the several classes are led from their receptacles into the jiggers by mechanical means.

The two crushing, etc., apparatus are usually in alternate use, and the arrangement is such that the drip of either wash drum is carried to the elevator, *b* 7.

The sorting is done by twelve boys in contract, and the transportation of the products performed by the two laborers engaged at the same time in the rubbish dressing works.

V.—The Crushing of the Ores With "Cornish Rollers."

The *crush stuff*, which contains the copper pyrites in heavy seams, or more or less coarsely disseminated, has a size of one and one-half to two inches, and is broken down to pieces of eight mm, or about one-third of an inch, which operation yields at the same time proportionate quantities of fine grit, sand and dust. One set of cylinder rollers, *c* 1, is used for coarse crushing, and the other, *c* 2, for fine crushing.

The diameter of the cylinders is thirty-nine inches, and their length ten and a half inches; their peripheral velocity is 2,5 to 3 feet, so that fourteen to eighteen revolutions per minute result.

The cast iron mantle rings of the rolls are cast in chill boxes, and are conical inside, the diameters being thirty-one and one-half and twenty-nine inches. They are fastened to the cast iron core, of corresponding form, by means of four bolts. The pillow blocks of one roller shaft are fixed on the cast iron bed frame, while those of the other roller are moveable, so that it can move out in case too much or too large pieces of ore—causing danger of breakage—should get between the rollers. The moveable roll is held up to the other by powerful rubber buffers.

The crush or roll stuff is fed from the hopper on to the rollers mechanically, with a percussion box or shoe. This consists of a trough seven feet long, twelve inches wide and eight inches deep, open on top. It is made of two inch plank, and lined inside with sheet iron. It is set on an incline of 12°, being hung on the back or high end with iron rods to the hopper, and resting on a roller in front. It is pushed back from fifty-five to seventy times per minute by a cam, and sprung forward again by a rubber buffer, whereby the material is moved forward, and drops through a slit in the bottom between the rolls. The quantity of feed is regulated partly by the length of the stroke, and partly by the greater or lesser tension of the buffer.

For the classing of the crushed roll stuff, there are at present eight sieve drums. One of these, the preparation drum, *c* 3, is situated alongside the rollers, *c* 1; a second one, *c* 4, opposite the first, will come into use with the rollers, *c* 2. The pulverized roll stuff runs from the rollers, *c* 1, directly into the preparation drum, *c* 3, and the material retained by this, consisting of ore insufficiently pulverized, is raised by means of the elevator, *c* 5, back into the feed trough of the fine rollers, *c* 2, and thence through its drum, etc.

The drip or screening of the 8 mm. holes of the drums, runs into the elevator basin, *c* 6, and is lifted into the top sieve drum of the classing apparatus, *c* 7. This consists of seven sieve drums, which in dimensions and arrangement are identical with the ones previously described. The screens of the five upper ones, and also those of the preparation drums, are of sheet steel; those of the two lower drums are of sheet copper.

The reserves of the drum fall into their respective compartments of the store-box, and are carried from these, partly by their own gravity, partly by mechanical means, into five automatic continuous jiggers; the coarsest sands from the screenings of the seventh drum are also given to a jigger, while the rest of the pulp is condensed in the funnel apparatus, *c* 8, and then lifted to the V boxes for further sorting or grading.

The seven classing drums yield 8 and 5,6 mm. gravel, 4, 2.8, 2 and 1.4 mm. grit, 1 and 0.7 mm. sand, and finer sand and slum.

With one set of rollers two to two and one-half tons roll stuff can be pulverized per hour.

The supervision of the classing drums, rollers and the auxiliary appliances, is the part work of one man only.

(To be Continued.)

Subscribers are requested to examine the printed address on their papers. If mistakes occur *at any time* please report them to this office. The last figures (at the extreme right) represent the year that your subscription is paid to. Next to these the day and month is represented. For instance, your subscription being paid to July 4th, 1876, it would be represented, viz: jal 4 76; or 4j176; or jn1 4,76.

The immense sales of Hale's Honey of Horehound and Tar proves that the people consider it the only sure remedy for coughs and colds and all pulmonary diseases. Sold by all druggists.

Pike's Toothache Drops cure in one minute.

Award of Premiums at the Mechanics' Fair.

The following is a complete list of the award of premiums made up to Thursday, the 14th inst. Additional awards are still to be made by the Board of Managers. Unless otherwise specially stated, all are first premiums.

Cash Premiums.

George West: Best Special Exhibit of Grapes, $25.00.
Dr John Strentzel: Tropical Fruits, $25.00.
H W Crabb: Largest Collection and Variety of Wine and Table Grapes, $20.00.
Mr Tristram: Mission Grapes. $10.00.

Gold Medals.

C Newman & Co: Best display Glassware.
Hueter Brothers: California made Varnish and Artists' Materials.
Pioneer Woolen Mills: Woolen Goods.
Tubbs & Co: Manila Rope.
W F Palmer: Edge Tools.
E K Howes & Co: Woodenware (sweepstakes).
Cornell Watch Co: Watches.
John Roach: Mathematical Instruments.
Linforth, Kellogg & Co: Largest and Best General Exhibit Agricultural Implements.
J Neumann: Best display of Silk Culture.
Consolidated Tobacco Co: Best Exhibit of California Tobacco and Cigars.
Will & Finck: Cutlery.
Pacific Saw Co: Best general display of Saws.
California Standard Sack Co: (Garlands.) Spiral Needle for Overhand Sewing Machine.
G W Swan: Box Nailing Machine. Special Premium.
Bradley & Rulofson: Best general exhibit in Photography.
National Tube Works, Dunham, Carrigan & Co, agents: Boiler Tubes and Flues.
California Furniture Company: Best general display of Furniture.
Carvill Manufacturing Company: Best display of Carriages.
W. T. Garratt: Best display of Brass Work, (sweepstakes).
W K Vanderslice & Co: Largest and Best General Exhibit of Silver ware.
C Jas King of Wm & Co: Best Exhibit of Hermetically sealed goods.

Silver Medals.

A Paltenghi: Statuary, Marble Mantle.
Bergman Bros; Rockingham and Yellow Ware and Terracotta Vases.
Mrs Anna Getz Lucas: Best display of Wax and Preserved Flowers.
Main & Winchester: Best General Display of Harness and Saddlery.
H Royer: Frilled Rawhide Goods.
Hawkins & Cantrell: Portable Hoisting Engine.
C O Farciat: Pump and Condenser.
J M Eckfeldt & Co: Best General Exhibit of Wire Goods.
A L Bancroft & Co: California Publications.
J S Hittell: Resources of California and History of Culture.
Union Pacific Silk Manufacturing Co: Silk Ribbons
Nelson & Doble: Blacksmith's Tools.
G W Swan & Co: Dovetail Boxes.
B F Freeman & Co: Stair Newells and Banisters.
M Fulda & Sons: Wine Casks.
P Liesenfeld: Cabinet Work and Superiority of Cushions, Billiard Tables.
S S White: Dental Goods and Appliances.
Joseph Wagner: Grain Operator.
Fisher & Harford: Best Conchological Display.
Gustave Mahé: Golden Wine.
Emil Boesch: Lamps and Reflectors.
A Eisenberg: Clocks and Chronometers, Home manufacture.
Lelia Curtis & Co: Wood Engraving.
Wing & Co: Lasts.
Mrs J G Bead: Cbe ills Embroidery,
Florence Sewing Machines.
Locke & Montagne: Best General Exhibit in the Class.
Honsewortb & Co: Albatypes.
Lucas, Gesner & Co: California made Plaster.
Prescott, Scott & Co: Ont Cast Iron Gears.
Pacific Wire Manufactnring Company: California made Wire.
San Francisco Gas Light Company: Ammonia.
Standard Soap Company: Standard and Toilet Soaps.
Goodwin & Co: Second Best General Display of Furniture.
Jacob Zech: Best Pianos on Exhibition.
S. P. Taylor & Co: Best Printing, Book and Wrapping Paper.
California Rock Drill Co: Rock Drill.
Parks & Lacy: Best General Exhibit of Tunneling Machinery.
J. C. Sendeling: Bakers' Rotary Blower.
Kimball Manufacturing Company: Second Best Display of Carriages.
Weed & Kingwell: Display of Brass Work.
Cooper, Jones & Cadbury: Best Display of Plumbers' and Gas Fitters' Goods.

Memorandum of Diplomas.

Robert Samisch: Painting on Porcelain.
F Seregni: Penmanship.
Samuel McDowell: Carpet Beating Machine.
S Lachman & Co: White Wine.
Lang & Co: Muscatel Wine.
J Browell: Chimney Tops.
F B Burney: Fire Escape.
W Jones: Files.
E F Menomy: Cement Pipe.
J B Owens: Fire brick and Iron Stove Pipe.
Eureka Marble Works: Marbelized Mantels.
G Hays & Co: Galvanized Architectural Iron Work.
J K Firth: Mechanical Drawings.
J W Bones: Architectural Drawings.
John Mallon: Glass Cutting.
California Pottery and Terra Cotta Works: Terra Cotta Ware, second Premium.
New England Glass Co: Flint Glassware.
Mrs A O Cook: Samples of Preserved Flowers.
Mrs Albert G Nye: Prepared Mosses.
Mrs C M Chapman: Human Hair.
Weaver, Taylor & Co: Rubber Goods.
F X Kast: Children's' and Misses' Shoes.
P Kelly: Best Display of Boots and Shoes.
H N Cook & Co: Hose and Leather Belting.
Parke & Lacy: Combined Engine and Boiler.
Treadwell & Co: Yacht Engine.
Treadwell & Co: Portable Threshing machine, (Hoadley's).
Treadwell & Co: Gardiner's Governor (Engine).
Prescott, Scott & Co: Horizontal Engine (Cortiss).
U. S. Salamonder Felting Co: Boiler Felting.
Cooper, Jones & Cadbury: Keystone Injector.
Cooper, Jones & Cadbury: Steam Gauge.
D Hicks: Book Binding.
LeConnt Bros: Best general display of Stationery.
J J Knowlton: Ink and Mucilage
F M Trnworthy: Improved Rubber Printing Wheel.
Thomas Saywell: Best display Gladiolas.
E A Upton: Best display of Dahlias.
D Tisch: Best Foliage and Colored Leaf Plants.
F Bailey & Son: Exhibitors of Encalyptus Seedlings.
Jonothan Begg: Best collection of Conifers.
W Brehmer: Collection of Cereals.
Thos W Appleby: Tree Ferns.
Gilbert & Moore: Rustic Letters.
C Jurgen: California Glue.
Chemical Paint Co: Chemical Paint.
Pacific Rubber Paint Co: Rubber Paint.
A Nahl: Crayopaque Drawing.
T G Cockrill & Co: Sour Mash Whisky.
J Renz: Blackberry Brandy.
S Lachman & Co: California Grape Brandy.
W Faulkner: Rum Punche.
McMillan & Kester: Syrups and Cordials.
Sweetser & DeLong: Best Cider Vinegar.
Schultz & Fisher: Superior Engraving and Designing in Silver, second premium.
Cornell Watch Co: Watch Cases.
R F Rochicioli: Galvano-Plastic work.
San Francisco Plating works: Plated Ware.
B W Jackson: Abalone Shell Jewelry.
Mrs Letitia Ferris: Glove Fasteners, California invention.
American Tract Society: Best general exhibit of Bibles and Fine Binding.
A L Bancroft & Co: General exhibit of Printing, etc.
Detrick & Co: Grain and Flour Bags.
Alex Mackay: Domestic Carpet.
A Viannay: Dress Silk and Weaving.
Joseph Green: Striped and Checked Silk Ribbons,
W S Brown & Co: Silk Thread and Twist.
Flint, Peabody & Co: Paper Barrels.
S P Taylor & Co: Best display of Book Printing and Wrapping Paper.
Pacific Cordage Co: Manila Paper.
W G Conklin: Bilge Water Gauge.
Osgood & Stetson: Ships' Lanterns.
Britton, Holbrook, & Co: Reflectors.
Wiester & Co: Washing Machine.
Joseph Bros: Yontbs' Clothing.
Lancaster & Nortbon: Coats.
P Beamish: Gent's Underwear.
T Rodgers Johnson: Military Clothing.
Pillsbury, Adair & Co: Edge Tools, second premium.
Osborn & Alexander: Mechanics' Tools.
C F Marwedel: Moulders' Tools.
E D Morgan: Sash Balance.
Sanborn & Byrnes, Stair Newells and Banisters, second premium.
Kimball Manufacturing Company: Baskets.
S F Steam Brush Factory: Brooms and Brushes.
Jacob Unna & Sons: Stable Brooms and Feather Dusters.
Robinson, Fowler & Co: Metallic Socket Brooms.
Geo H Mixer: Iron Bungs.
Henry Wass: Corking Machine.
F C M Fenn: Meat Shaver.
E K Howes & Co: Refrigerator.
Adolph Grossman: Scrubbing Brush.
Household Furnishing Company: Household Furnishing Goods.
Jacob Strahle & Co: Cabinet Work and general exhibit of Billiard Tables, second premium.
Georgs Tieman: Surgical Instruments.
J H A Folkers & Bro: Surgical Bandages and Orthopedical Appliances.
Y G W Parkhurst: Scales.
Bryant & Taylor: Combination Bank Locks.
Mrs. Quigley: Spirit Levels.
S Farjeon: Watchmaker's Lathe.
Weyl & Co: Best display of Bronzes.
Frank Bros: Harvestors.
Kimball Manufacturing Company: Road Scraper.
James Harris: Tubular Iron Harrow.
Pillsbury, Hussey, Adair & Co: Lawn Mower.
H Walton; Side-Hill Plow.
C Bonney: Hay Rake.
Treadwell & Co: Thresher and Separator.
Price Press Co: Best Hay Press, Excavator and Ditching Machine.
Marcus C Hawley & Co: Best Sulky Plow.
Frank Bros & Co: Grain Binder.
E N Dudgeon: Improved Hydraulic Jack.
R B Prince: Silk Cocoons, second premium.
L G Yates, M D: Conchological Display.
F Gruber: Taxidermestry.
Hermann & Co: Fossils.
A C Robison: Curiosities.
Thos Butterfield & Co: Best display of Wool.
Journal of Commerce: Best display of California Products.
John Bollman & Co: Best Cigarettes.
Henry G Hanks: Best Mineralogical Collection.
Crystal Salt Works: Salt.
J G Pettit: Wood Engraving, second premium.
Griffith Griffith: Polished Native Granite.
Mrs J G Read: Afghan.
Mrs John Cornwall: Silk Bed Spread.
Mrs S Kincaid: Crotchet Bed Spread.
Mrs Sutherland: Two-Thread Bed Spread.
Mrs H Stettin: Colored Silk Embroidery.
M Lichtenstein: White Silk Embroidery and best general display White Underwear.
John F Snow & Co: Cleaned Kid Gloves.
Mrs H Cantel: Cleaned Laces.
S H Roberts, Lace Ruffling.
C J Weldon: Improved Buckles for Ladies' Hose.
Mrs Maxfield: Best exhibit of Bands and Supporters for Ladies' Garments.
May Arnold: Gent's Shirt, band made.
Mrs C Sullivan: Stamps and Stamped Goods.
Mrs A Young: Netted Lamp Mat.
Mrs L Allison: Worsted Lace Shawls.
Mrs T Atkinson: Combed Worsted Wreath.
C D Alden: Raised Worsted Work and Pictnre Needle Work.
Mrs E Barringer: Best display Paper Patterns.
M Frend: Corsets.
New Wilson Sewing Machine Co: Best display fine Needle Work and Embroidery.
Davis Sewing Machine Co: Display of Work of all Kinds, second premium.
Mrs Crosby: Blue Satin Quilt.
Treadwell & Co: Wood Carving Machine.
H P Gregory: Four Sided Moulding Machine (Fay's.)
Carl Weinberger: Saw Gummer and Sharpener.
Warren Holt: Head Tenon Machine.
C Bonney, Jr: Wood Shaping Machine.
L C Mumford: Circular and Jig Saw.
Wellwood Murray: Knitting Machine.
Davis Sewing Machine Co: Automatic Bobbin Winder and Vertical Feed.
Weed Sewing Machine Co: Needle Bar.
John Lewelling: Best collection California Dried Fruits.
Wm R Smith: Best collection Fruit Confections.
Brittan, Holbrook & Co: Medallion Range:
Brittan, Holbrook & Co: Plain and Japanned Tinware
Geo H Tay & Co: Best display Stove Castings.
Locke & Montague: Vau's Urns.
Osgood & Stetson: Best Portable Range (Norman.)
Osgood & Stetson: Tin, Copper, Planished and Japanned Ware.
W Weymuller: Stovepipes Elbowe.
Thos Tweedals: South Sea Island Curiosities.
M Lynch: Best Sidewalk Skylight and Ventilator.

D. J. JAMES—Australian Colonies.
CHAS. T. BELL—Montana, Utah, Idaho and Nevada.
C. K. LAWTON—Santa Barbara County.

APPRECIATION ABROAD.—We copy tha following from the *Mining and Monetary Gazette*, of London, Eng.: "We deemed it advisable, as affording valuable information to our readers, to publish in recent issues of *The Gazette*, the full text of the "United States Mining Laws and Instructions, by the Commissioner of General Land Office," taken from our talented contemporary, THE MINING AND SCIENTIFIC PRESS, of San Francisco. The documents have now been issued in a handsomely-bound volume by Messrs. Dewey & Co., the publishers of our transatlantic contemporary, and it will be found very useful to those already interested in American mines, and to others who may be tempted to embark in that enterprise in the States."

WOODWARD'S GARDENS embraces an Aqnarnm, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

Mining and Other Companies.

Keystone Quartz Mining Company—Principal place of business, San Francisco, California. Location of works, Butte Township, Sierra county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on he 22d day of September, 1875, an assessment (No. 5) of fifty (50) cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, northwest corner Pine and Sansome streets, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the5th day of November, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 29th day of November, 1875, to pay the delinqnent assessment, together with costs of advertising and expenses of sale.

Office, northwest corner Pine and Sansome streets, San Francisco, California.

Hope Quicksilver Mining Company—Location of principal place of business, San Francisco, California. Location of works, Cinnabar Mining District, Sonoma County, State of California.

Notice is hereby given, that at a regular meeting of the Board of Directors, held on the 2d day of August, 1875, an assessement (No. 2) of Five cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, Room 2, No. 408 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 9th day of September, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 30th day of September, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

Office, Room 2, No. 408 California street, San Francisco, California. JACOB HARDY, Secretary.

POSTPONEMENT.—The date of the delinquency of the above assessment is postponed to the 8th day of October, and the date of delinquent sales to November 1st, 1875. By order of the Trustees. J. HARDY, Secretary.
September 8, 1875.

SECOND POSTPONEMENT.—The date nf the delinquency of the above assessment is postponed to November 9, 1875, and the day of delinquent sales to December 1, 1875. By order nf the Board of Trustees.
JACOB HARDY, Secretary.
San Francisco, October 8, 1875.

Mount Auburn Gold Quartz Mining Company. Location of principal place of business, San Francisco, Cal.

SAVE $50! WHY PAY $85?

SEWING MACHINES.

REDUCED PRICE, $35.

HOME and HOME SHUTTLE SEWING MACHINES.

Reduced to Live and Let Live Prices.

These Machines are superior to any and all; nice sewers, straight needle, two threads, shuttle, lock-stitch, the simplest and cheapest, and the lightest running first-class Machines in the market. To see is to convince yourselves.

The Hall Treadle for Sewing Machines.

The most important improvement ever made. It saves labor and preserves health. No more diseases and deaths, side or back aches from using Sewing Machines. No teaching required. A child can run it. Always starts the right way. Never goes backwards and breaks things. Can be stopped instantly. With it on your Machine, you can do double the work you can without it. Fifty stitches can be made with one pressure of one foot. It can be applied to any Sewing Machine. Approved by Massachusetts State Board of Health (see Official Report 1872), Massachusetts Medical Society and Massachusetts Charitable Mechanics' Association. The HALL TREADLE is a part of all HOME MACHINES sold by us.

The Hall Treadle Grinding Machine

Must be seen to be appreciated. For a Farmer or Mechanic to see it, is to buy one. It is an indispensable articl in every Farm-house, Shop or Hotel.

The Hall Treadle Jig Saw and Boring Machine

Is an accomplishment in every Workshop. The HALL TREADLE is applicable to all machinery requiring a foot-power—Sewing Machines, Grindstones, Jig Saws, Turning Lathes, Jewelers' and Dentists' Lathes, etc. Send for Circulars.

VOLUME XXXI Number 17.

Enameled Water Pipe.

A question which has puzzled property owners and house builders for years past has been, "What kind of pipe is best for bringing water into our houses and grounds?" Lead pipe has long since been considered as dangerous to health. Lead pipe lined with tin is very expensive and has a questionable record. Plain cast and wrought iron will rust and corrode. Iron lined with cement is full of imperfections. Iron lined with porcelain or glass would be a good conduit, but is found impracticable from its brittle, unbending, unelastic nature. Galvanized iron, which on its discovery bid fair to solve the problem, is found seriously wanting, particularly where iron, lime, sulphur or alkalies form any part of the ingredients of water. Recently our attention has been called to an indestructible enamel coating for the inside and outside of pipe, which is now being extensively adopted by water boards and private parties. The coating is put on with great heat and resists all corrosive tendencies; neither alcohol, acids, alkalies, sulphur, salts of any composition, or other corrosives in solution dissolve it; it forms a durable, elastic, indestructible coating for both the inside and outside of the pipe. The testimony of chemists, the practical experience of numbers using it and the readiness of the manufacturers to guarantee its claims, lead us to believe that at last this vital but perplexing question has been answered and a reliable means found for supplying pure water for domestic use at a reasonable cost and with perfect satisfaction.

On this coast, where such large quantities of heavy, expensive pipe are used for mining purposes, in addition to that for domestic use, the question in relation to water pipes is even of more importance than elsewhere. The mining pipe must be of the best character, made to stand a heavy pressure, and, being originally so heavy and expensive, should be durable to be at all economical. The only means as yet adopted here to preserve the wrought iron of which the pipes are usually made, is to coat it inside and out with tar or asphaltum, put on while hot by dipping the pipe in it. Recently, however, the pipe to which we refer has been introduced on this coast by the National tube works company, owners of the patent, and has already been extensively adopted in the mining regions of California and Nevada.

The National tube works company are probably the largest manufacturers of pipe in the United States, owning two very extensive factories, one at Boston, Mass., and the other at McKeesport, Pa. An idea may be gained of the extent of these works from the engravings on this page. The company manufacture seamless wrought iron lap welded pipe, coated inside and out with enamel, or plain, made under a patented process owned by the company. The rolling mills are new and cost upwards of one million dollars. The consumption of sheet iron is not less than 150 tons per day, Sundays included, the year round. They employ from 800 to 1,000 men at the McKeesport mills alone. All the iron used is domestic—from the ore to the pipe. The capital is all American, as are everybody connected with the institution. The patents used are also all American inventions. The furnaces at these mills have never been let out since the day they were first built except for repairs, and on Sundays, when they are let down, not out.

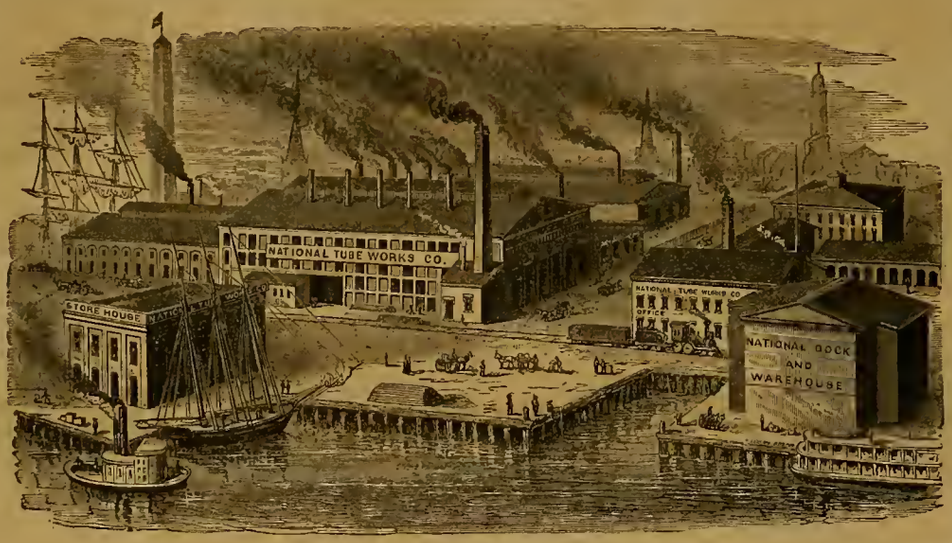
At the McKeesport mills is the enameling branch of the business. The process is one of bath and baking, and is patented. It is put on at from 250 to 350 degrees of heat, according to the size of the pipe. There is no common property in nature in solution that will touch it. To salts, alkalies, sulphur, etc., it is found to be a most perfect repellant. It meets the difficulties that have existed all along in the use of pipe, for the conveyance of water, and is regarded by those who have used it as a very great invention.

Another use of value for this enamel is for gas pipe. By using the enameled pipe, we are informed, that a gasometer is increased in capacity one-third; the pipes being smooth and frictionless. The New York gas company is now using this pipe for the street lamps. No heat will affect it nor will cold.

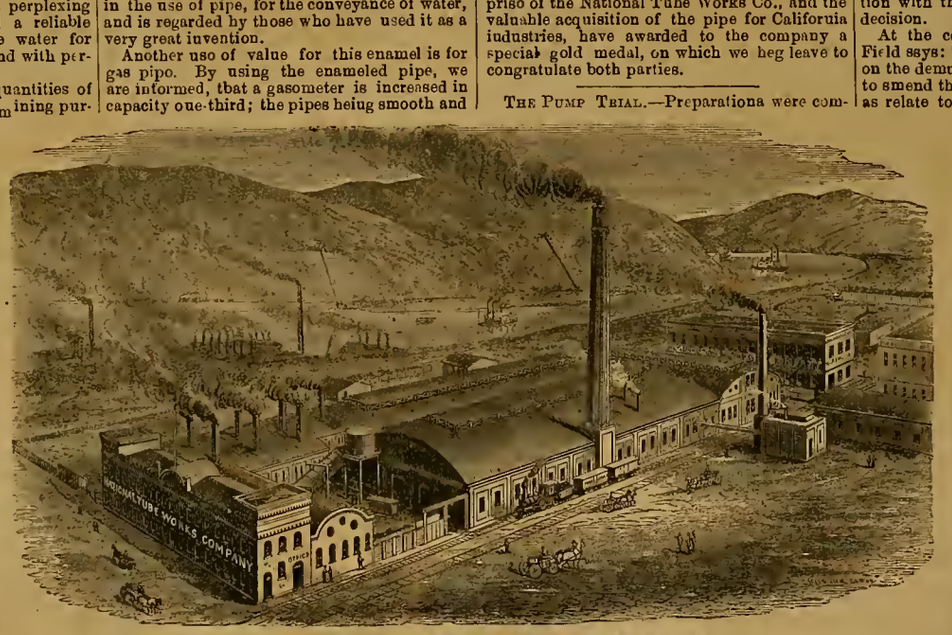
From what we are told it is probable that the seamless, lap welded, wrought iron, enameled pipe will be of great value in the mines, where sulphur is so destructive. Pipe of this character is now used for pump columns in the Consolidated Virginia and other mines. They are made also of very light gauge for deep air shafts. Large quantities are now being sent here for hydraulic mining purposes, for which they are very valuable, there being no rivets to cause friction. Another great advantage is, that they are made in long lengths.

They are made of all gauges up to 15 inch. The manufacture of these gauges has been attended with a great deal of difficulty and expense. The Siemens gas furnace is used—this company and one other owning the sole right for the United States. By the patented processes now in use, it is comparatively easy to make the pipe.

The managers of the recent Mechanics' Institute Fair, appreciating the skill and enterprise of the National Tube Works Co., and the valuable acquisition of the pipe for California industries, have awarded to the company a special gold medal, on which we beg leave to congratulate both parties.



NATIONAL TUBE WORKS, BOSTON, MASS.



NATIONAL TUBE WORKS, M'KEESPORT, PA.

THE PUMP TRIAL.—Preparations were completed for beginning the great pump trial at the Mechanics' Pavilion this (Thursday) afternoon. As we stated in our last issue one day will be allowed to each pump, consuming four days in all. In the SCIENTIFIC PRESS of next week we hope to be able to give a full and accurate report of the trial and announce the award of the judges. The trial has awakened a large interest in mining and scientific circles, and we have but to add that we hope to see the best pump win.

THREE of the Chinamen engaged in the riot at Bakersfield last week have since died.

Giant Powder.

We have been requested to correct some misapprehension which exists concerning the decision rendered by the courts, in the case of the Giant Powder Co. *vs.* The California Powder Co., *et al.* The suit was for an alleged infringement of three letters patent, all of which were re-issues, numbered respectively 5,799, 4,818, and 4,819; No. 5,799 is the important one, being that under which the company now operates in making its powder. No. 4,818 was a patent for a compound of nitro-glycerine with gunpowder or gun cotton. No. 4,819 was for a patent for a compound of nitro-glycerine with rocket powder. Neither of these two latter patents have ever been used in any shape by the company. The validity of these two re-issues was assailed on the alleged ground that they describe and claim a different invention from that described and claimed in the original patent; and their validity was the question presented by the demurrer, the judges holding them invalid.

In the decision of Judge Field, however, he states explicitly, "upon the validity of the latter re-issue (No. 5,799) no question is made." This is the Dynamite patent under which the Giant powder company is manufacturing their powder; so the Giant powder is manufactured under a distinct, independent patent, known as the Dynamite or Giant Powder patent—a patent having no connection with the two patents affected by the late decision.

At the conclusion of the decision Judge Field says: The defendant must have judgment on the demurrer, with leave to the complainant to amend the bill by striking out all such parts as relate to the patents Nos. 4,818 and 4,819. The counsel of the Giant Powder Co., however, then decided not to amend the bill at all, but to allow judgment to be entered up against them on all these re-issues in order to get the case before the supreme court of the United States. This was done to settle the matter as speedily as possible, although the judge had stated that upon the validity of what the company consider the important patent (No. 5,799,) no question was made. The Giant Powder Co. therefore consider that the decision, though apparently adverse, incidentally confirms the rights upon which it mainly relies, and touches only those of no special value. As the papers are now being prepared to send to Washington, the controversy between these two companies will, no doubt, now be speedily adjudicated. The Giant Powder Co. are confident that they will be able to prove that their patents have been infringed upon, and have taken this opportunity to take the question before the highest court of the United States.

THE contract for running the tunnel of the Sonoma & Marin railroad through the *puerto suello* has been re-let, this time to M. W. Connolly and J. B. Hinkle, of Petaluma. The tunnel will be 1,100 feet long, 12 feet 8 inches in the clear at the bottom and 16 feet high. Work was commenced last Monday at both ends of the tunnel with a force of 120 men, and the tunnel is to be completed by July 9, 1876. The entire cost will be about $100,000.

THE stockholders of the Woodland, Clear Lake and Humboldt railroad company had a meeting at Woodland on Saturday last.

CORRESPONDENCE.

Eastern and Central Nevada—The Mines of the Tybo and Reveille Districts.

MESSRS. EDITORS:—Whatever the general public may now think of the mines and mineral resources of Eastern and Central Nevada, there exists no longsr a donht in the minds of those best acqnainted with thess sections of the value, prodnctiveness and permanence of the numerons mines locatsd in tbeir midst.

Five years ago, and Eureka scarcely had an sxistence, except upon the map, while to day it is the recognized center of a rich and extensive mining region. Trne the east cannot compare with the west, either in the magnitude of its wealth or in its claims to public attention, but it can, nevertheless, present a showing which will bear comparison with that of any other quarter of Nevada. When we consider the character of the developments which have been carried out, and the quantity and quality of the precious metals which have been extracted from its various mines within the past six years, we are lost in astonisbment at the apathy displayed by the operators of your city, when dealing with the stocks of the aforesaid mines. The future of Eastern Nevada is now, however, assured; for, if mineral wealth and great natural resources should entitle it to the favorable consideration of the mining men of the city and coast, then there is an absolute certainty of its fnture being unusually bright and prosperous. These things are becoming every day more msnifest, and the time is not far distant when mines that are now being thought little of, will become as prominent bullion producers as any in the State of Nevada.

Nye county has always been noted for the richness and extent of its minersl deposits. It has, however, until lately, labored under many disadvantages. Capital, enterprise, and energetic action were wanting to fittingly develop and utilize its bonndless resources and bring to light the vast treasures that lay dormant within the bosom of its majestic hills.

Professor Frank Stewart, of Virginia City, one of the Centennial commissioners from Nevada, one of the most accomplished geologists and mineralogists of the Pacific States, writes to the *Enterprise*, in No. 10 of a series of articles entitled, "What I Saw in the Great East." In that letter he discnsses the merits of Tybo and Reveille districts, and since he is no mean authority in things pertaining to the mineral kingdom, I have no hesitation in quoting from him, or rather from the Eureka *Sentinel* of a recent date. He says:

Tybo.

"Twenty miles south of the Hot Creek range of monntains, in a deep mountain gorge, lie the famous Tybo mines, five in number, whose united lineal extent covers nearly 5,000 feet of lode matter. These mines are owned by the Tybo Consolidated mining company of San Francisco, where they have been lately incorporated.

"The only point at Tybo where the everlasting limestone ceases, and where a more propitious geological feature appears, is at the lower town, or at a point where the smelting works and reduction works have been erected. At the point designated there is a wide belt of quartzite and porphyritic matter, in the center of which is the celebrated Two G mine, which has been developed to the depth of about 300 feet (nearly 400 feet in depth now). It has a good dip towards the northeast, has a northwesterly and southeasterly strike, and is trnly a well defined fissure vein of great value, and is from three to nine feet in dismeter (main average seven feet). Like the South Prussiau, at Jefferson, the Two G contains well defined strata of fine ore, with alternating layers of galena and other base metals. For this reason the owners have wisely concluded to work the ores by the dual process of smelting and milling. At Tybo there is now in complete running order a twenty-stamp mill and a first-olass furnace of thirty tons reduction capacity each twenty-four honrs. With snch complete reductiou appliances the mines at Tybo cannot fail to prove successful, for the ore is rich by assay and practically inexhaustible."

The foregoing, though dealing fairly enough with the state of things at Tybo, is yet far from accurate, bnt then it must be borne in mind that nearly five months have elapsed since the writer met the professor and State geologist, Whitehill, at Tybo, and much has been done since then in the way of substantial improvement and development. Of

Reveille District

And the Gila mine, now so nnjustly condemned by stock operators, he writes at length, and since I cannot quote him in extenso, I subjoin the concluding portion of his remarks on this now mnch maligned mine and district:

"The principal mine now being worked at Reveille is the Gila. The ore is shipped twelve miles away to a ten stamp mill, which I have have been told works the minerals very satisfactorily. The ore is unusually rich, yielding from $150 to $2,500 per ton, assay value (general pulp assays $400 per ton), and yst the mins managers of the Gila have, in their supreme ignorance, rnn three tnnnels into the hill, and were last summer, at their third level, only fifty-eight below the ontcrop. Being in the heart of a great zone of quartzite and porphyry, and having, as it does, the true striks and dip of first class qnartz lodes, the Gila onght to be one of the best mines on the coast, and if it does not prove so the fault will be with the mine management."

The foregoing extract gives the unbiased opinion of an old and experienced mining expert, whose jndgment is worthy the respect and attention of the people of San Francisco who hold Gila stock. That the mine is good there is no doubt, bnt unfortnnately for its reputation, the cessation of active operations at the mills, which had to be shnt down for repairs, took place at a most inauspicious moment; yet for all this, had the late panic not intervened at the time it did, the prics of Gila would be far above what it is at present. However, since the mill starts up on the 14th proximo, we may soon hope for a greater measure of success than has yet attended the Gila, there being a large qnantity of high grade ore on hand to run upon. The mine is also in a very desirable condition, and although brilliant as has been its past, I am fully satisfied that its future prosperity will eclipse all that we have known of its past history. J. D. P.

Tybo, Oct. 15th, 1875.

Toughened Glass.

The invention of M. de la Bastie, by which he toughens glass by plunging it in an oil and tar bath, was, according to the Pittsburg *Herald*, anticipated at the works of Bakewell, Pears & Co., as early as 1822. It was used to temper blown glass previous to its being cut. A large kettle was filled with the wsre, and fish oil poured over the whole till all the space was occupied. A fire was then put under the kettle and kept up till the highest attainable heat was secured. Then the fire was allowed to die out and the glass to cool gradually. In this way the object was effected, and there was no more trouble by the breaking of ware on the cutter's stone. In recent conversstion on the subject with Professor Sweet, of Cornell University, he stated that his brother, a manufacturer of springs in Syracnse, had succeeded in making glass very hard and strong by an oil bath used for tempering his springs. The glass was so strong that strips of from one to one and a half inches in width, and of the thickness of ordinary window glass, could not be broken by the hands. However, the slightest check upon the surface with a diamond resulted in the total disintegration of the glass, it being reduced to fine powder throughout its entire extent. It would appear that the statements that have been made relative to nicety in the preparation of the quantity of the different materials which form M. de la Bastie's bath have been considerably exaggerated. The experiments at Bakewell, Pears & Co.'s works, and Mr. Sweet's experiments, indicate that oil is sufficient to harden and strengthen the glass; but the statements made in regard to cutting the glass, after tempering, at the Pittsburg works, do not agree with those made in regard to the breaking of the glass, resulting in its total destruction, and from the slightest scratch. A piece of iron or steel, when broken, may be again joined together, but the tempered glass, as far as yet discovered, can never be mended when once broken. This will, unless further improvement is made, greatly limit its usefulness. It is to be hoped that further experiments may result in the production of a glass which, while it is as hard as that produced by M. de la Bastie's method, will still be really tough.

ENGINEERING FEAT.—A remarkable feat of engineering has recently been accomplished by Messrs. Weeks & Bros., well knowu builders in this city. This feat consisted in the removal of a wall 65 feet in hight, 60 feet in length, and of an average thickness of 14 inches. The wall having been found to encroach upon neighboring property, it was necessary to take it down in the usual way and re-erect it, or to adopt the alternative successfully carried out by Messrs. Weeks & Bros. They carefully removed the masonry which joined the wall to the rest of the building, and pierced the wall at the bottom with holes, into which a double set of needle beams were inserted. These beams formed ways upon which the wall was slid along. The beams were thoroughly greased and shoes placed upon them. The entire weight of the wall rested upon these shoes. Screwjacks were then applied and carefully manipulated by trained workmen, so that while the wall was slid bodily along its parallelism with the opposite wall of the building and its perpendicularity were all the while maintained. The entire weight was said to exceed 270 tons. After the preliminary preparations were made only about five hours were absorbed in the removal of the wall to the position it was destined to occupy. This wall has been joined to the building again, and it is stated that a large economy was the result of the operation. The successful removal of this wall will doubtless be the beginning of many similar removals. Messrs. Weeks & Bros. have exhibited great ingennity and skill. Our readers will comprehend that the utmost care was necessary to remove a wall of this kind, balanced upon so narrow a base, without toppling it over or cracking it.—*N. Y. Artisan.*

A New Self-Acting Saloon.

The London *News* of a late date says: "An invention which has been favorably regarded by the leading authoritiss on the subject of channel navigation, and which notably is nnder the attentive consideration of Mr. Mills, engineer in chief to the London, Chatham and Dover railway, with a view to its adoption by that company, was yesterday explained by its originator, Mr. Alexander Walker, C. E., to a party of professional and scisntific gentlemen, assembled at the Terminus hotel, Cannon street. In order to understand the nature of Mr. Walker's plan for accomplishing that great public benefit which has hitherto fallen short of practical attainment, we must imagine a longitudinal section of an ordinary passenger steamboat betwsen Dover and Calais. Fore and aft we perceive two circular hall-shaped saloons, each divided into three compartments. The middle space is intended for the general use of the passengers, and the division on either side is severally for ladies and for gentlemen. Each of these saloons is carried on a strong central shaft or spindle, which passes vertically through the saloon itself, then through a ball and socket joint fixed in a rigid iron framing beneath the saloon floor, and so downward to a hnge spherical counter-weight at its lower end. This globe of solid metal is calculated to compensate donbly the weight of the saloon with its complement of passengers. This might be taken, at a maximum, as eleven tons, and the counter-weight of twenty-two tons wonld then be ample to secure a free action in accordance with the simple principle of gravitation. Nothing could be more nicely accnrate than the maintenance of a true level on a line with the earth in Mr. Walker's working model; nor is it easy, looking at the design on this miniature scale, to detect any point so weak as to invalidate the entire project. The dimensions of the vessel on which it is proposed to make the first trial of the new saloon are 190 feet length between perpendiculars, 20 feet breadth, 14 feet 3 inches depth of hold, and 824 tons burden. The number of passengers accommodated on board will be 150, that is, sixty-five in each saloon. These proportions, however, may he increased or diminished; and it is claimed for the invention that, without loss of stowage, it is applicable to ships not only of all sizes bnt of all descriptions, and that it may be easily adapted to troopers. Ventilation is easily provided for by fans of novel conetruction; and, on the whole, Mr. Walker seems to have spared neither thought nor pains in perfecting his invention."

KID GLOVE MAKING IN FRANCE.—There are three departments in glove making in France—cutting out, sewing, and finishing; that is to say embroidering the back, making the button hole, and setting on the button. It is the work of men to cut out the glove; bnt women place it on the iron hand which forms the measure, strike it with a stamp, and prepare it for the cutter. This is not difficult work; it is done by the piece, and they receive tenpence for five dozen. The sewers are less favored; the price paid for a dozen pairs of lady's gloves with one button is 3s. 9d.; ont of this they had to pay fifty per cent. to their employer, and forty per cent. goes in silk, which they find; so that it only leaves about threepence-halfpenny a pair. If it be asked how many pair a good workwoman can complete in one day, the answer will be that if working twelve hours without interruption, she may manage to get through four pair; but most of the hands only do two pair and a half. This arises from the attention they must pay to household work. Glove making requires the most perfect cleanliness; not only are soiled gloves returned to the sewer, but she is obliged to pay for the leather. Four pair will be thus paid at the rate of elevenpence, from which a deduction must be made for lights of two and a half, leaving eightpence-halfpenny. These wages are still lower in Aveyron and Haute-Marne; but in the department of Isere, this occupies no less than twelve thonsand women, representing a value of sixteen million francs. The manufactory at Grenoble employs twelve hnndred cutters-out, making five hundred and forty thousand dozen. Those who work the back of the glove and finish it off are better paid; seven-and-sixpence is given for a dozen, bnt then the silk is not found. It requires six or seven hours to make a pair of embroidered gloves; supposing she does a pair and a half a day, she will not earn that sum in a week. At this work a woman must sew regularly, and have neither children nor many household matters to distract her attention, as it requires great nicety and skill. In Paris the work is done at the workshop of the maker, where it can be better performed, and the highest class of embroiderers obtain there about twelve shillings a dozen.

NAVIGATING TORPEDOES.—Denayrouse, in France, has invented an apparatus intended to place submarine torpedoes in position unobserved by the enemy. Experiments lately made in England before the torpedo committee of the Admiralty, have proved that a man provided with this apparatus can remain under water, without any communication with the surface, for two hours at a time, and being guided by a compass illnminated by a lamp, is able to move in all directions, or to a before determined place. He can thus remove torpedoes placed by the enemy, or can place them where desired. The committee, after a thorough examination, have declared themselves to be perfectly satisfied that everything claimed for this apparatus can be accomplished with it.

Manufacture of Machine Paper-Hangings.

The first process in machine-printing is preparing the ground of the pattern to the color or shade required. This is done by passing the paper through a machine which sprsads over it an equal coating of color, by means of brushes moving transversely. As the paper comes off the machine it is quickly dried, by being drawn through a hot air chamber. All the paper is treatsd in this manner, except the very lowest qnalitiss, in which case it receivss the requirsd tint during the process of manufacture. The paper for satin grounds is prepared in a similar mannsr to that nsed for block papers, and polished afterwards by means of revolving brushes with French chalk. The printing machins contains a varying numbsr of rollers or blocks, constructed of wood with a metal axle, and they print the pattern npon the paper. Great care and exactness are required in the preparation of these rollers, and a separate one is required for each color. The design having been traced upon them, it is raised on the surface by driving slips of copper into the wood, and filling up with *felt* the portions which are to make the impression. In some patterns as many as twenty colors are used, requiring as many separate rollers. To print a flower, for example, several blocks are required, and in a design embracing various light shades and deep colors, each shade and color requires a corresponding roller. By changing the colors very different effects may be produced and various qualities of the same pattern are produced with the same set of rollers. Of course, every new pattern requires a fresh set of rollers, and a large sum is frequently expended in producing a novel design. The rollers or blocks are arranged in a circular form around the machine, which is about 10 feet in hight. Each roller having been supplied with its proper color from a corresponding trough, the paper is taken up by the machine in a continuous web, or at least in pieces from 5,800 to 6,000 yards in length. The rollers press the paper against a large central cylinder, and as it moves along it receives the various colors in succession, and comes out with the design fully developed. Many of the colors are printed one on the other, bnt blending is prevented by the use of several varieties of size. There are machines for printing different numbers of colors; one with two rollers prints about 500 pieces in an hour according to the pattern; one with twelve rollers about 200 pieces; and one with twenty rollers about 100 pieces in an hour. A machine with two rollers produces the printed paper at the rate of four miles an hour; and one with twelve rollers at about half the speed. Plain paper is produced from pulp at the rate of one mile an hour. The printed paper is marked off in twelve yard lengths during the process of printing, and on leaving the machine it is dried by means of hot air. The rolling-up of the paper is also effected by machinery.

Although machine paper hangings have been wonderfully improved during the last twenty years, there is still a wide difference between them and those printed by hand blocks. They are printed npon thinner paper, with less color on the prepared ground and in the formation of the design. Machine paper hangings are, upon the average, about a third, and those in general use about half the price of those printed by hand labor. About three-fifths of the paper hangings sold are produced by machinery. They have provided the cheapest possible means of giving a clean and cheerful aspect to all kinds of rooms, and are used by all classes of the community.

A Water Motor.

At the Sulzbach Alteuwald colliery, near Saarbrucken, Prussia, machinery has been established for the transmission of power from a steam engine at the surface, by a column of water circulating nnder pressure, the circumstances of the case not admitting of the establishment of a direct acting steam pump nnder ground. The mine is sunk 306 yards below the surface. The piston rod of the high pressnre engine above is conuected with the pressure plungers, each of which plungers is connected with the underground engine by a tube filled with water. The last mentioned engine consists of four pressure pumps arranged in pairs, and between each pair is placed the working plunger of one of the mine pumps. When the engine on the surface acts the power is transmitted by one pressnre plunger through one water tube to a pair of pressnre pumps nnder ground, and thence to one working plunger, which either aspirates or forces air, according to its position. The opposite pair of pumps and connections work conversely. The water is forced into an air vessel and thence throngh the rising main, 303 yards in hight, in one lift to the surface. On the change of stroke, the water in the cylinder of the pressure pump rises in the second water tube and follows the retiring pressure plunger at the surface, the power supplied by the descent of water in one column being sufficient, with the exception of a slight allowance for friction, to effect its return in the other. If the cataract pauses of the engine at the surface are not too long, the discharge is practically continuous. The *Engineering and Mining Journal*, from whose translation of the German description we condense the above, adds that at the Phœnix mine in Cornwall, England, an arrangement of similar description, consisting of a plunger attached to the main pumping engine, connected by a length of tube with a water pressure engine in another shaft, has been at work for ten years.

Scientific Progress.

Constitution of the Sun.

Professor Balfour Stewart, in an address before the late meeting of the British Association of Science, on this subject, said: Several new metals have been added to the list of those previously detected in the solar atmosphere, and it is now certain that the vapore of hydrogen, potassium, sodinm, rubidinm, barium, strontium, calcinm, magnesinm, alnminum, iron, manganese, chrominm, cobalt, nickel, titaninm, lead, copper, cadmium, zinc, uranium, cerinm, vanadium, and palladinm occur in our inminary.

If we have learned to be independent of total eclipses as far as the lower portions of the solar atmosphere are concerned, it must be confessed that as yet the npper portions—the outworks of the sun—can only be successfully approached on these rare and precious occasions. Thanks to the various government expeditions despatched by Great Britain, by the United States, and by several Continental nations—thanks, also, to the exertions of Lord Lindsay and other astronomers—we are in possession of definite information regarding the solar corona.

In the first place, we are now absolutely certain that a large part of this appendage unmistakably belongs to our luminary, and in the next place, we know that it consists, in part at least, of an ignited gas giving a peculiar spectrum, which we have not yet been able to identify with that of any known element. The temptation is great to associate this spectrnm with the presence of something lighter than hydrogen, of the nature of which we are yet totally ignorant.

A peculiar physical structure of the corona has likewise been suspected. On the whole, we may say that this is the least known, while it is perhaps the most interesting, region of solar research; most assuredly it is well worthy of fnrther investigation.

Magnetism.—In ordinary observation, magnetism is scarcely known except as existing in iron, and especially in steel, and as related in some obscure manner to the earth. But there is reason to believe that it is one of the most extensively diffused agents in natnre. It can be traced not only in iron, but also in every snbstance into which iron enters into composition. It is found in nickel, cobalt, chromium, and other substances, and even in some gases. Wherever a galvanic current exists in nature, whether produced by chemical action, or appearing in the thermo electric form as originating from the effects of heat at the place of union of different substances, magnetic effects can be elicited. On the larger scale, it is certain that the whole earth acts as a combination of magnets, and there is reason to think that the sun and the moon also act as magnets. The laws of magnetic force, however, have been experimentally examined with philosophical accuracy, only in their connection with iron and steel, and, by inferences bearing considerable probability, in the influences exerted by the earth as a whole. The ferruginous minerals of the formula Fe_3O_4 possess the property of attracting iron and its filings, and are called natural magnets or lodestones. Experience has demonstrated that the attractive action of magnets takes place in a vacuum and through all bodies, whether gaseous, liquid, or solid, when they are not themselves magnetic. All the properties of natural magnets may be permanently communicated to needles or to bars of steel properly tempered, which are then said to be magnetized, and take the name of artificial magnets.—*Scientific American.*

Gender in the Hemp Plant.—The influences which determine gender in the hemp plant have lately been made the subject of study by M. Haberlandt. Having satisfied himself that neither the size nor the specific nor absolute weight of the seede gave an indication of gender, he made a series of experiments to ascertain how far the factors of growth influenced the result. He found that neither the amount of water afforded nor the quantity of space allowed for the growth of the roots had any perceptible influence in causing a preponderant development of male or female plants; but there appeared to be such an influence in withdrawal of light and strong manuring. In eight cases the proportion between male and female plants was altered from 3.7 to 5.7; and only in three pots were all the plants female. These were plants which seemed to be beyond the influence produced, and they were greatly delayed in their development. The author believes the relation between strong manuring, and perhaps shading, on the one hand, and the formation of the female flowers on the other, may be accepted.

Testing Oils by Electricity.—Professor Palmieri has invented an instrument for testing oils and textures by electricity. It is said to be capable of showing the quality of olive oil, distinguishing it from seed oil, and also detecting the mixture of the latter with olive oil. At the same time it affords a means of testing seed and other oils, and will indicate the presence of cotton in silk fabrics.

An Interesting Electrical Experiment.—In a recent number of *Comptes Rendus* M. Lippmann describes the following curious experiment: A rubbed piece of resin is brought near the surface of water in a glass jar, the water communicating with the ground by a platinum wire. Positive electricity comes from the ground and is distributed over the water surface, and bubbles of oxygen are liberated from the electrode. The hydrogen that was combined with the oxygen remains in excess, and, in some sort, *masked*, so long as the water is electrified. On removing the red thin hydrogen escapes in bubbles. The masked hydrogen is neither combined nor dissolved; one cannot remove any part of it either by diffusion or by oxidation, or by any physical or chemical action which leaves the electric charge intact; yet it is there, for it is liberated when the rod of resin is removed. The words *dissolved* or *combined* may apply to hydrogen held in the interior of a certain mass, but here we seem to have an example of another order of material connection. The masked hydrogen is entirely held at the surface of the water; we might change the entire mass without affecting it.

Ocular Inequality.—A writer in *Science Gossip* speaks of the difficulty which some persons experience in the use of binocular microscopes, owing to a focal difference in the eyes. In a case mentioned one eye was far sighted, while the other was near sighted. For reading purposes, this person wears a pair of spectacles in which the one glass is made for the far sight, while the other is a plain glass, the left eye being near sighted, and consequently requiring no aid from spectacles with which to read. Instances are cited of persons who, while employing both eyes for ordinary vision, usually employ only one in reading. If any difference of the kind exists between the visual powers of a pair of eyes, it may be readily detected. Hold up a piece of card before one eye, so as to cut off its field of view, and then look at some object before you with the other. Then gradually bring the card before the other eye, and view the same object. If the object is seen with the same distinctness in each case, then your eyes are perfect as regards the balance of their foci; if not, then there is focal difference more or less decided It would no doubt be advisable to take account of the very frequent difference of focus, in selecting a pair of spectacles.

Earthquake Investigations.—Father Bertelli, an Italian monk, for several years past has made a study of the tremblings of the earth, and more especially those which are so extremely slight as not to be perceptible save by pendulums placed in the fields of microscopes. In one year he recognized 5,000 of these movements; and graphically representing the same over many years by a curve, he finds that the line corresponds neither with the thermometric curve, nor with the tidal phenomena, nor can it be brought into relation with the distances or positions of the sun or moon. With the barometric curve, however, it is otherwise; and it appears that in the large majority of cases, the intensity of the movements augmented with the lowering of the barometric column as if (as the investigator states) the gaseous matters imprisoned in the superficial layers of the earth escaped more easily when the weight of atmosphere diminished.

Effects of Electricity on Plants.—The effects of electricity on plants have not been closely studied. It is known to produce contractions in sensitive plants, and to retard the motion of sap. M. Becquerel has studied its influence on germination and development. It decomposes the salts contained in the seed, the acid elements being carried to the positive pole, and the alkaline portions to the negative. Now, the former are hurtful to vegetation, while the latter favor it. M. Becquerel further examined the influence of electricity on the color of plants. The discharge from a powerful machine produced remarkable changes of color on the petals, due, he thinks, to the rupture of cells containing coloring matter.

Hygroscopic Paper.—The *Journal of the Franklin Institute* gives a mode of preparing a useful hygroscopic paper, by Percy Smith. A bibulous paper is impregnated with a concentrated solution of chloride of cobalt. It is very sensitive to atmospheric variations, being blue in a dry atmosphere, changing to red when the air becomes humid. Four observations a day, made for a year, with every precaution, prove that this paper may be employed to indicate readily and precisely the hygrometic state of the air.

To Preserve Metallic Sodium.—According to Bottger, if sodium be placed in alcohol until its surface becomes brilliant, and then in naphthalic ether chemically pure, and finally in a concentrated solution of naphtualine in naphthalic ether, the metal may be preserved unalterable, with its luster unimpaired, for a long time.

MM. Robin and Leoros, experimenting with *noctiluca*, the little organi me which produce in great part the phosphorescence of the sea, found that on passing an electric current through some sea-water in the dark, its course was marked by a luminous trace, the phosphorescence of the animals being excited by the electricity.

Mechanical Progress.

Production of Bessemer Steel in the United States.

The eight completed Bessemer steel works in this country, though doing a good business, were not fully occupied during the year 1874. The production of this class of steel in the United States is rapidly increasing. Starting in 1867, with a production of only 3,000 tons, we find the production in 1874 has reached 176,579 tons. The rate of increase will be seen by the following tabular statement:

1867	3,000	1871	45,000
1868	8,500	1872	110,000
1869	12,000	1873	157,000
1870	40,000	1874	176,000

Of the total product during 1874, there were 144,944 tons employed in the manufacture of steel rails. The 31,635 tons not so used, were employed in the manufacture of spring and bar steel railway axles, crowbars and other railway tools, wagon and carriage tires, machinery and steamboat forgings, etc.

The English Product of Bessemer Steel.

The quantity of Bessemer steel made in the United Kingdom during the past five years is stated as follows, by competent authority, in gross tons: In 1870, 215,000; 1871, 329,000; 1872, 410,000; 1873, 496,000; 1874, 540,000. We give these figures for comparison with our own achievements in building up the Bessemer industry, and that we may call attention to the fact that when the three new Bessemer establishments are all put in operation—making eleven in all—the capacity to produce Bessemer steel will be as great in this country as it now is in Great Britain.

The Production of Steel other than Bessemer

There are forty-two establishments in the United States, making cast, puddled, blister and open-hearth steel. The aggregate production of these establishments in 1874 was 47,481 tons. The production of open-hearth or Siemens-Martin steel is steadily increasing in the United States. There are now thirteen establishments here, which are using the Siemens-Martin furnace, whose aggregate product is about 10,000 tons. In 1872 it was only 3,000 tons.

As a further encouraging evidence of the rapid progress of steel making in this country, we clip the following extract from the *American Manufacturer*, from which journal we have also condensed the above:

During the calender year 1874 our imports of steel ingots, bars, sheets and wire amounted to $2,678,611, against $3,865,316 in 1873; $4,206,087 in 1872; and $3,460,735 in 1871. Our exports of these articles in 1874 amounted to 343 net tons of the value of $29,557, against twenty-six tons in 1873 of the value of $5 481, nine tons in 1872 of the value of $3,624 and thirty tons in 1871 of the value of $7,364. The increase our exports and the decrease of our imports of these commodities in 1874 are very marked, and the statistics of the exports and imports of the manufactures of steel for 1874, are equally encouraging to the home manufacturer of steel or steel products.

New Mode of Raising Sunken Ships.—Numerous suggestions have been propounded with regard to raising the British ironclad, recently sunk by coming in contact with another monitor off the English coast. With one exception, they have all been based upon some plan for raising the sunken ship directly from her present position. One engineer, however, presents a new plan, as follows. "It appears to me worth consideration whether the object sought does not permit of being attained by the application of power in a different direction—viz., traction, using the bottom of the sea as the plane along which to move the load. I would recommend that, after the guns and all other moveables have been removed, to make fast to the wreck by chain cables passed through the portholes, and yoke on some of our most powerful steamers, harnessed abreast as horses, and try the practicability of sledging her into shallow water, where she could then be more efficiently dealt with. It is simply a question of power, and not difficult to calculate the amount required, where the load is known, and approximate allowance for friction to be overcome. The trial (compared with the value of the prize) would not be costly, and it may perhaps be regarded as a less formidable undertaking than moving the Great Eastern from her bed, after the first failure in attempting to launch her. A little pulling was done on that occasion, but on a small scale, owing to the confined space available."

Pernot-Martin Furnace.—It appears that the products of the Pernot-Martin furnace are likely to give rise to a new nomenclature. This furnace turns out what is almost a new metal, with a highly granular fracture, and the engineers who have visited the Saint Chamond works, distinguish between it and Bessemer metal without any hesitation. Is this metal wanting in homogeneity? Does not the question of the duration of the operation in the Martin process preponderate in attaining a good molecular arrangement? The operation seems to be performed rather too quickly with the Pernot-Martin furnace, and, perhaps, if a minute analysis were made of the grains, the carbon would not be found distributed in a sufficiently uniform manner?—*English Paper.*

Multiple Engines.

There was quite a discussion on the subject of multiple engines at the late Manchester meeting of the British Iron and Steel Institute. As a general thing, the speakers did not believe in their economy; but there was such an array of a "practical facts" presented in their favor, that it was hinted that a recommendation would be made to the Manchester Steam Users' Association to erect, at an early day, a pair of experimental engines for the express purpose of giving the principle a thorough practical test. During the discussion Mr. Wroa, a large steam user, but not an engineer, remarked that he owned two cotton mills, one running 57,000 spindles, and driven by a triple cylinder engine, and the other running 47,000 spindles driven by a quadruple engine. During the last six months the engines with the triple cylinders had consumed fifty-tons one hundredweight per week, while the quadruple engines had only used thirty-five tons twelve hundredweight per week, the mill in which they were fitted turning out nearly as much work as the larger one. Mr. Wroa stated further that the triple cylinder engines had used, during the twelve years they had been put down, about two and a half pounds of coal per horse power, while the quadruple, which had been down only twelve months, had consumed only one and a half pounds per horse power. Mr. Wroa declared that the "saving was obvious" when the directors of the company found that the consumption of coal was reduced from sixty to thirty tons.

Mr. Adamson remarked: It must be admitted that steam engineering is advancing with rapid strides, and a few years may produce unlooked for changes. Twenty years ago the proposal to construct a quadruple engine would have been regarded as a freak of eccentricity, now we have such curiosities—and valuable ones, too—as the three-cylinder engine of Brotherhood and Hardingham, the three-cylinder quick-speed engine of Mr. Willan, and the compound engine of Messrs. Field and Cotton, besides others, that a few years ago would have been ridiculed. Every year we are getting nearer and nearer to obtaining the theoretical effect of a pound of coal; and although it is, no doubt, practically impossible to reach that pitch of perfection, something has been done towards it, though much more remains to be done before it is generally attained.

Economy in Furnace Heating.

A correspondent of the *Scientific American* writes to that journal as follows: "In an article recently published in your paper on combustion, the practice of admitting air to the top of a fire for the purpose of consuming the carbonic oxide is recommended. The theory of course is an old one, but is it a correct one in an economical point of view? In practice it is found, I believe, that the more air you admit to a fire, the more rapidly is the heat evolved carried up the chimney. It is no use making the fuel give out more heat if we cannot retain that heat and utilize it. At the great factories at Mulhouse, in Germany, a series of experiments was tried in relation to the combustion of smoke, with a view to the saving of fuel. The result was disappointing. When the necessary amount of air for the perfect combustion of the smoke was admitted to the fires, there was a loss of heat. The same result was described by practical engineers in London. At Mulhouse the practice now is to admit as little air as possible to the fires (one-half of the amount formerly admitted) and to 'feed a little at a time and often.'"

The journal quoted comments on the above as follows: "We do not think these matters are so definitely settled that a general rule can be given which will be applicable to all cases. We have known of a number of cases in which it seemed to us that there was an advantage arising from admitting air above the fire. We do not at present recall the experiments to which you refer, and would be glad if you would send us a record, in case it is convenient."

Punching Boiler Plates.—At the late meeting of the Iron and Steel Institute, held at Manchester, England, Mr. Adamson, one of the leading speakers, presented some rather severe strictures on the mode of boiler construction. He denounced the practice of "punching" holes as "barbarous." All rivet holes should be truly cylindrical, and drilled through with both plates *in situ*, so as to insure perfect accuracy in riveting. He was convinced that if boilers were made by engineers of recognized skill and care, with suitable tools for drilling the rivet holes, and fitting the various parts together, that pressures of 100 to 150 pounds might be used with less risk than at present attaches to boilers carrying only fifty pounds per square inch.

Hemp and Wire Rope.—Round steel wire rope will bear more than double the weight required to break iron rope of similar diameter.

company now have in the permanence and richness of the mine, the superintendent is preparing to further open it for extensive working, by running a tunnel on a level 100 ft lower than the first, and with additional facilities for smelting and retorting the ores.

KERN.

The Defiance.—*Southern Californian*, Oct. 14: Mr. P. Reddy is at Darwin, engaged in overlooking the erection of the machine for the famous Defiance mine. He says he will be able to get it completed in 30 days, when the mine will turn out 150 bars of bullion per day. It will soon take 3 teams per day to move the bullion from Darwin, with the mill now turning out 120 bars per day. The bars weigh 85 pounds each, and large teams and heavy wagons are required to move them to Caliente, the next station beyond us on the Southern Pacific railroad.

Ore from Keanville.—We are in receipt of some fine specimens of ore from the Al. Bunnell mine, sent by Mr. J. S. Collins. They have gone the rounds of the town, and have excited general interest. We are glad to see some spirit of that kind of enterprise, which enables us to know something practical of the mines in the county. Mr. Collins has the thanks of the office and the people.

Good Assay.—From Col. Burr, one of the owners of the Buonell gold and silver mining company, we learn that the last assay made in October of a 4 ft depth, was $1,010 silver and $251 gold; total, $1,261, and improves daily.

LAKE.

Advance in Quicksilver.—Middletown correspondence of the Lakeport *Bee*: The advancing price of quicksilver is stimulating renewed activity at the mines in this vicinity, and were it not for the stringency in the money market, the coming winter would chronicle heevier shipments of the metal than were ever before known from this locality. As it is, old locations are hunted up and re-recorded, and there is a general sharpening of picks and drills, and other preliminary mining arrangements going on that indicate a vigorous prosecution of the work of prospecting for the enchanted metal.

PLACER.

Mining About Auburn.—*Argus*, Oct. 16: The St. Patrick's mines are showing better than ever, and everything indicates a prosperous future. The mill during the past month, crushed 400 tons of ore, yielding 806 ounces of gold. This falls short of the expectations, but owing to the need of repairs on the ditch, the water was turned off for some time, reducing the running time of the mill to 20 days, and thus cutting down the yield, almost one-third. The ore dumps at the mine and the mill platforms are crowded with fine ore, and as the mill is now running to its fullest capacity, to make up for lost time, we may look for a big clean-up at the end of the current month.

Doing Well.—*Herald*, same date: The St. Patrick company cleaned up again last week after 22 days' run with remarkably good results obtaining something over 800 ounces of gold. The pay chute in the Crater mine is wide, and the rock at the present depth uniformly rich, making it unquestionably a good mine. Under the superintendency of Mr. Townsend the mine is opened in good shape, and with comparatively few men, rock is taken out as fast as the mill can possibly crush it, something that with ever so large a force, has not been done before; thus demonstrating to a nicety the advantage of having a thoroughly practical miner for superintendent, instead of a California street sharp, whose conceited theories have ruined the reputation of many good mines.

Ore from Good Friday Mine.—Ten tons of ore recently crushed at the Pugh mill, from the Good Friday quartz mine, yield $1,800, an average of $180 per ton. Work is steadily progressing in this mine, and from the above the indications are that it will prove one of the substantial lodes of the district.

SOLANO.

Quicksilver Furnace.—*Times*, Oct. 16: E. N. Smith, of this city, has just completed a four and a half ton quicksilver furnace at Mr. Loop's mine, which is situated about half a mile southeast of the Brownlie mine. Considerable rock of a promising quality has been gotten out, and the furnace will be put in operation soon. This furnace is of about the same size as that at the St. John's mine.

Nevada.

WASHOE DISTRICT.

Ophir.—Gold Hill *News*, Oct. 12: Daily yield of ore, 350 tons. The ore breaets continue to both look and yield well, the ore extracted being of a good milling quality. A shipment of bullion to the value of $40,000 was made on the 6th inst., and another to day of between $65,000 and $70,000, proving beyond a doubt the richness of the body of ore extending upward from the 1465 ft level. The mills are all running steadily, and a sufficient amount of ore is being extracted to create a reserve supply in case of need at the mills. The up-raise from the 1300-ft level is still in good ore and is looking well. The old station on the 1100-ft level has been reopened, and a main working drift, intended to cut and prospect the ore body found in the raise on the 1200-ft level, is now being driven vigorously forward. On the 1700-ft level the east cross cuts, Nos. 1 and 4, are being steadily advanced. In west cross-cut No. 4, on this level, a station is being cut out for an air engine, designed to sink a winze at that point, down to the 1800-ft level. The main north drift on this level is also being driven ahead toward the Mexican south line.

Consolidated Virginia. — Daily yield, 650 tons of ore. The ore breasts are looking well and yielding the usual amount of rich ore, with no signs whatever of exhaustion. The mills are all running steadily, and the yield of the mine for October will be fully up to the returns of last month. The new hoisting engines of the C. & C. shaft will be ready to start up in a day or two more, when sinking the new shaft will be crowded downward at a rate that will astonish even the mining sharps of the Comstock. The regular almost daily shipments of bullion are being made, and the prospects of the mine were never better than at the present. The usual monthly dividend of $10 per share, aggregating $1,800,000, was declared on the 7th.

Lady Bryan.—Owing to a breakage of a pump flange a delay of a day or two was caused in the sinking of the shaft during the week; everything is, however, again in good running order and the sinking going ahead as usual. The north drift on the 380-ft level is steadily advancing, without change of value to report. The main south drift on the 380-ft level is in a distance of 381 feet, the face in very soft, favorable vein matter. At a distance of 200 feet south of the shaft a west cross cut has been started from the main south drift on the 380-ft level, the face of which is showing some very favorable quartz and ore.

Sierra Nevada.—Sinking the new shaft is making rapid progress, the new drills working well, both in the bottom of the shaft and in the main west tunnel at the 1000-ft station. These drills are driven by compressed air, and add greatly to the progress of both drift and shaft. The north and south drifts on the 700-ft level of the old shaft are steadily advancing, without any changes worth recording. Everything in and about the mine is in good working order, and the prospects are encouraging.

Silver Hill.—The 4th station is completed, and a drift started to cut and prospect the ore vein at that point. On the 3d station level the drifts have shown the ledge to be over 200 ft in width, the most of which is composed of a fine character of quartz with streaks and spots of ore that give good assays in both gold and silver. The recent rich ore developments in the Justice prove almost conclusively that the Silver Hill has a continuation of the same ledge, and that the finding of the same ore body further to the south is but a matter of time. The managers of the mine feel greatly encouraged. Its prospects are certainly looking up.

Imperial-Empire.—Daily yield, 40 tons of ore. This ore is being extracted from the ore stopes between the 1850 and 2000-ft levels. The stopes are looking well and promise a considerable yield. Another mill—the Boston—has been added, which will increase the working capacity of the mine 15 to 20 tons per day. An air connection has been made between the ore stopes and the 1930-ft level, which greatly aids the work in that portion of the mine. Burleigh drills have been placed in the east drift on the 2000-ft level, which will greatly expedite that portion of the work.

Yellow Jacket.—Both the north and south winzes, sinking below the 1840-ft level, have reached the 1940-ft level, at which point the bottom of both are perfectly dry, and station are being opened for the purpose of cross-cutting and prospecting the ore vein. Each of the winzes will be sunk 15 or 18 ft below the stations to form a sump for water in case any shall be encountered while cross-cutting the ledge. Nothing new of any of the cross-cuts on the 1740-ft level.

Chollar-Potosi.—Daily yield, 50 tons of ore, the assay value of which is $33 to $35 per ton. This ore is being taken from the old upper workings. The south drifts on the 1150, 1250 and 1350-ft levels are severally being advanced at the rate of 25 ft per day. No important changes at any point to record. Sinking the new shaft is making steady and favorable progress, the rock in the bottom blasting out finely.

Belcher.—Daily yield, 150 tons of ore. The ore breasts are looking finely and yielding well. Prospecting the 1600-ft level is being advanced as rapidly as possible, with every expectation of good results. Everything in and about the mine is in first-class order, and the future of the mine is putting on quite a favorable aspect.

Overman.—The pumping machinery is all again in good running order, and the water is being rapidly lowered in the main shaft. The prospecting on the 900-ft level is still pushed rapidly ahead. No change of interest to report. The south drift from the bottom of the winze on the 1100-ft level is also being rapidly advanced.

Baltimore and American Flat.—Sinking the incline below the 900-ft station is making rapid progress. No change worth noting. It is the intention in a short time to commence cross-cutting the ore vein on the 850-ft level. Preparations for receiving the water when the cross-cutting is done have already commenced.

Europa.—Sinking the shaft is making splendid progress, the rock in the bottom blasting out finely, and the work being pushed with all the energy possible. A drift has been started from the 320-ft station to cut and prospect the ledge at that point, and new life is being infused in every portion of the work.

Utah.—The hoisting works of this mine were destroyed by fire last Sunday evening, and the new and powerful pumping machinery but recently erected considerably damaged. All work in the shaft and mine is of course suspended for the present. The shaft is but little damaged, and the management, with their usual force and vigor, are rapidly clearing away the ruins and preparing to erect a new building, and put everything in good running order at the very earliest day possible.

Leo.—The work of driving the prospecting drifts north and east from the bottom of the winze goes steadily on, and good progress is being made. The water has increased a little, but not enough to retard the developments. The vein material in the face of the north drift shows considerable improvement this week; the quartz veins are stronger and of better character, and the indications generally are more encouraging.

Silver City.—Plenty of good milling ore continues to come from the northern extension of the main drift, and the work of exploring for more good ore, and putting the mine in good productive paying shape, goes ahead with energy and good judgment.

Buckeye.—Sinking the shaft is making fair progress, the bottom in quartz and ledge matter of a highly encouraging character.

Woodville Consolidated.—The erection of the new pumping machinery is making favorable progress. Nothing doing in the mine at present.

Julia.—Sinking the shaft is making excellent headway, the Burleigh drills working with the utmost perfection and the work being pressed ahead with all possible activity. The quartz and ore veins in the bottom of the shaft are increasing in size and are of a highly encouraging character. The face of the main southwest drift, on the 1400-ft level, is being advanced by the aid of the Burleigh drills at the rate of 6 ft per day, the face in ledge material of a highly encouraging nature. This drift is being run nearly parallel with the ore vein, is perfectly dry, large and roomy, so that cross-cuts can be started at almost any time to prospect the ore vein. A fine streak of quartz and ore has been following the face of the drift for some distance and still continues. The face of the main south drift, on the 1000-ft level, is in a much softer character of quartz and porphyry mixed, with a considerable seepage of water in the face. The prospects of this drift are also looking more encouraging.

California.—Sinking the winze below the 1550-ft level is making good progress. It is now down 95 ft, the bottom still in rich ore. The north drift on the 1550-ft level is also being steadily advanced, the face in good ore. On the 1550-ft level the main drift north of cross-cut No. 6 is again being advanced toward the Ophir line. A winze has also been started in cross-cut No. 5, to connect with the main north drift on the 1550-ft level, for ventilation purposes. The main north drift on the 1400 ft level is in a distance of 312 ft from cross-cut No. 3, the face in a much better character of ore than has been before encountered. The upraise on the 1400-ft level is up 105 ft. The battery mill is almost completed; the pan mill is also fast approaching completion. The hoisting works of the C. & C. shaft will be ready to start up in a day or two more. The shaft is down 605 ft to-day, the sinking progressing at the rate of 4 ft per day.

Justice.—The fine ore body being developed in the southern portion of this mine, from the 600-ft level upward, is of great value and importance, as showing a bonanza being found in the southern section of the Comstock. This ore body at the 600-ft level was estimated to be at least 50 ft wide, but its real dimensions are not yet ascertained. It shows more and more in both width and length, and although not of uniform quality, it is certain that there is a large amount of good paying ore developed in the Justice mine.

Lady Washington.—The huge pumping engine is completed, the pump rods are finished and in place, and in fact, with the exception of placing a small portion of the valve gear and the finishing up of the mason work around the new boilers, everything is in the most complete running order. It will probably take about a week yet to get everything in place and working smoothly. Then the water will be drained and the shaft started downward for the north end of the Justice big bonanza.

Bullion.—Sinking the main incline is progressing at the rate of 4 ft per day, the bottom in good working ground. The main north drift on the 1700-ft level is steadily advancing along the west wall of the ledge, the face in a fine character of quartz, and spots of ore of a very encouraging character. The combination drift on the 2000-ft level of the Imperial is making fine progress.

Union Consolidated.—The bottom of the winze below the 1300-ft level is looking well, and the face of the north drift on the same level is showing a promise of the development of an ore body in that direction in a very short time. Everything working well, and good progress is being made in both the winze and drift.

North Chipman.—Sinking the new shaft is making splendid progress, the bottom in soft, favorable material, of a very promising character. The managers of this mine are going to work in good style, and evidently mean business. The location is an excellent one, and it seems strange that it should have lain so long neglected.

Prospect.—No change of material in either drift or shaft, and no increase of water in drift. The frame of the hoisting works building is being sided and enclosed, the extensive pit for the pump hole, excavated in the solid rock, is nearly completed, and the work generally is being driven ahead as fast as possible.

New York Consolidated.—Steam was gotten up this morning, and the new machinery tested, everything working with the greatest perfection. In a day or two more everything will be running smoothly, and the pumps will be set to work extracting the water, preparatory to resuming work on the lower levels of the mine.

Gould & Curry. — Repairing the main incline below the 10th station level is being pushed with all the vigor possible. The heat is intense, and but slow progress can be made at best. Nothing can be done toward the development of the 1700-ft level until the repairs are finished.

Mexican.—The quality of the ore in the north drift on the 1465-ft level is steadily improving. The ledge formation is also showing more compact and better as the drift advances. The winze on this level is down 94 ft, the quartz and ore in the bottom looking well.

Cosmopolitan.—Splendid ore is being taken from the face of the main tunnel, and the prospecting at other points is going ahead lively.

Savage.—The flow of water at the bottom of the main incline still continues too strong to permit of a resumption of the sinking. The main north drifts on both the 2100 and 2000-ft levels are being pressed ahead. No change in either to record.

Iowa.—Work progressing well, both in the cross-cut from the upper tunnel and the main west drift at the 420-ft station. In that drift the streaks of ore and quartz are becoming more concentrated and are getting on a much more favorable look.

Caledonia.—Sinking the new shaft is making excellent headway, the work being pressed with all possible vigor. The machinery is all working splendidly, and everything settling down in splendid shape for a good winter's work.

Sullivan.—The bottom of the shaft is still in the same very promising vein matter mentioned in last report, with no sign of west wall as yet. The surface grading and all other work is being pushed forward energetically.

Best and Belcher.—The rock in the face of the north drift, on the 1700-ft level, is in very hard blasting rock, so hard that but slow progress can be made, even with the aid of Burleigh drills driven by compressed air.

Crown Point.—The usual amount of ore is being extracted from the ore stopes on the 1500-ft level. Prospecting the 1600 and 1700-ft levels goes steadily ahead, without change or interuption of any kind whatever to report.

Hale & Norcross.—Prospecting the 2200-ft level is steadily progressing, with no new or very promising features to chronicle. Everything in and about the mine is in splendid working condition.

Rock Island.—The 600-ft station is completed, the pumps lowered and a drift started to cut and prospect the ore vein at that point. No changes to report of the prospecting operations on the 450 ft level.

Succor.—Both the west and north drift on the 550-ft level are steadily advancing without change of importance to report. The mill will be started up on Belcher ore in a day or two more.

Florida.—West drift going ahead. Water increases somewhat, but not enough to interfere with the work. Some very fine assays are obtained from the streaks and bunches of ore met with.

Sutro Tunnel.—Total length to-day, 11,170 feet. During the past week the rock encountered in the header has been somewhat harder and more easily managed.

Moore and Morgan.—A contract is being let to sink the shaft deeper. Rock showing both silver sulphurets and free gold has been found during the past week.

Washington Territory.

Mining Matters.—Walla Walla *Union*, Oct. 9: A correspondent writes as follows from Warrens, under date of 25th of September: With the approach of freezing weather our placer mining season is drawing to a close. The yield of gold from this camp has not been so great as heretofore, but the difference has not been so great as many would have us believe. Many of the long established claims are worked out or have ceased to pay, but on the other hand a number of new claims have been opened on outlying gulches, which have contributed something by way of compensation. On the whole, it is something in these degenerate days to have a placer mining camp somewhere near to hold its own. The only operations going on this season worthy of note in the quartz line, are those at the Rescue. During the winter and spring Mr. Leland had a small force of men putting the hoisting machinery in place and preparing to sink, and a shaft was commenced. After the snow had melted and the ground became dry the shaft was continued to a depth of over 70 feet, and drifts started each way on the ledge. To the west nothing was developed, and work was discontinued, but to the east, after running 20 feet or so, the drift came upon a seam of quartz of the rich description formerly taken out of the works above and worked by Gambel. This ore has continued to the present time of varying thickness but undoubted value. Within a few days past they have commenced stoping. The mill has undergone many repairs, but was presumed to be ready for operations a week ago. After crushing a few tons, however, some more changes were found necessary, but I am informed that crushing will go on again in a day or two. All those acquainted with the mine agree that they have several hundred tons of good rock for stoping actually in sight, as the saying is, and the prospects of the mine and company are therefore encouraging.

The War Ship of the Future.

The sinking of the ponderous British iroaclad *Vanguard*, by accidental collision with the *Iron Duke*, adds another to the long list of accidents which have destroyed or rendered useless the great floating fortresses which have lately become the pride of the British navy. These two ships were built after the same model. The *Vanguard* was a vessel of nearly 4,000 tons burden, built by the Lairds, at Birkenhead, and cost about $2,500,000. She was one of the fastest and strongest ships in the British navy, but one blow from the ram of her sister ship, whose bows she tried to cross, cut her open between two compartments, and so disabled her that she sank in an hour. The ease with which her destruction was accomplished shows how ineffectual is armor plating, as at present applied, to protect a vessel against the dangers to which it is most frequently subjected. Like Achilles, vulnerable in the heel, those ponderous iron batteries are vulnerable below the water line. The experiments lately conducted at Newport with torpedoes showed that these engines of destruction, formerly regarded by naval officers as ingenious but rather inoffensive toys for scientific landsmen to play with, are potent agents in skillful hands, and that no amount of armor plating will serve to protect the leviathans of the line from the vigorous attacks of these naval sword-fish. To meet these new conditions we shall probably have an increase of plating, so disposed as to protect the bottom, as well as the sides and deck; while plate must be piled on plate above if the naval architect is to hold his ground in the neck and neck race with the artillerist, who has so far managed to send his projectiles through whatever armor any ship now afloat has succeeded in carrying. In other words, the English naval constructors are going through an experience very similar to that which led to the abandonment of mail and armor for the protection of soldiers against the shafts and arrows of ancient warfare. As long as lances, arrows, swords and battle axes were employed, supplemented later by rude firearms of short range and little power, armor served a good purpose. With the improvement of the machinery of war, and especially the introduction of better fire-arms and more destructive field artillery, armor became worse than useless. It had grown heavier and heavier, but no man could have carried armor enough to make him invulnerable to bullets, and now the soldier is best equipped when equipped most lightly. If we are not much mistaken, the armor plating of vessels will soon be abandoned. Such ships, of small and steadily decreasing value in time of war, are a burden to a nation in time of peace. They are very costly, short lived under the most favorable circumstances, and liable to be rendered obsolete by the introduction of new guns and more formidable projectiles, as well as by adoption of new models. We think the English nation will grow tired of this kind of investment before long, and that if we possess our souls in peace for a few years longer, we shall have learned the folly of building great iron ships of war, without having to pay anything for the knowledge.

There are many considerations which lead to the belief that the war vessel of the future will be of very different character from the war vessel of the present time. Probably she will be of iron—possibly of steel—with a double skin, but without armor. She will be light, swift, heavily armed and capable of doing effective service as a ram. No nation will require a great fleet, for the reason that it will have no use for them. When troops are to be moved by sea, transports will be employed, sailing under convoy if protection against hostile vessels is needed. Great navies belong properly to the era of walled cities, fortified harbors and standing armies, and although they have outlived these evidences of early civilization, they have at the same time outlived their usefulness.—*Iron Age*.

Russian Way of Stopping Holes in Ships.—Russia is rapidly progressing in the practical industrial appliances as well as in the sciences and arts. In that country there has lately been invented, and successfully applied, a ready means of stopping holes made in ships by collision or otherwise. It consists of a plaster made of two rectangular sheets of canvas sewed together, bordered with rope, and containing a water-proof material. A sounding line has to be passed under the keel and brought up on the other side, then the plaster can be lowered to the hole and made fast. Several cases are cited in which this invention has been employed with advantage, and a large number of Russian ships are now furnished with such plasters. It is proposed that men be specially trained and ready for the manœuvring of the apparatus.

Interesting Object for Experiment.—In the Paris International Maritime Exhibition there is a small object deserving of notice. It is a platinum wire placed in a bottle and ignited by electricity from a bichromate battery. It is intended to be immersed in the sea, and the light emanating from it is said to attract an immense number of fishes. Experiments have been tried lately on the coast of the Cortes du Nord department with a fishing-boat, and have proved very satisfactory on a shoal of sardines. The glass must be green or black, otherwise the fish are frightened by the glare, and do not follow the submarine light.

An Old Georgia Silver Mine.

Twenty years ago, as the story runs, Mr. Pendley was living at Sugar Hill, Georgia, and was then engaged in gold mining with Moses Lott. Lott had heard of a very rich silver mine from John Lumpkin. Lumpkin had heard of it from a Baptist preacher, who lived near Carnesville; the preacher had heard it from a man who had died near him, and who, on his death-bed, had given the preacher a minute description of the mine and its surroundings. Lott told Pendley that the stranger on his death-bed said that he and other South Carolinians had come out among the Indians hunting gold and silver ore; that they crossed the Oconee at Hurricane shoals, proceeded along a well-known Indian trail to the Chattahoochee, went down it to the mouth of a large creek, and in hunting a place to cross, went up the creek some distance, where two of the Carolinians—the stranger being one—were captured by a company of Spaniards, were carried at night some four or five miles south of the head of the creek, and were put to work in a silver mine during each night, and just before day they took the silver ore upon their backs, went due south from the mine five miles to an island covered with an immense swamp growth, and in the middle of this island, in a rude shop, they worked ore and molded the metal into silver dollars; that when the Indians found them out they filled up the mine with timber and dirt, buried as much as a wagon load of silver dollars in the middle of the shop, burned down the shop, released the two South Carolinians and left; that one of the South Carolinians was lost, and that the dying man was on his way with the great secret, which he revealed to the preacher on his death-bed.

With this account Mr. Pendley set out in 1863 to find the mine answering to the description. It is situated two miles due north of Swanee creek, in Gwinnett county, and the island is on Beaver Ruin creek, five miles due south of the mine. On the island Mr. P. found cinders, Indian vessels and implements, and the hole in the ground which had been filled up by old Billy Chamblee, who cleared up the island, and who testified to having found the hole open. Mr. Pendley went to work on the old mine, and continued until his small capital was spent, and he suspended. When again his means enabled him to renew his labors, the war came on and forced him to defer it. In 1871 he resumed work again alone, followed the old tunnel by sinking shafts nearly two hundred feet, without finding anything but unmistakeable evidence of the old tunnel, which was filled with leaves, brush, oak post and timber. A few weeks ago he reached the end of the old tunnel, and found a vein of mineral ore one and a half feet thick and fifteen feet wide. Above it there is a layer of white clay; beneath it there is a hard yellow rock, and on each side there is a wall of very hard, blue sandstone. The ore consists of two layers, one bluish, the other reddish brown; is very soft—somewhat cohesive—and very heavy.—*Covington Enterprise*.

A large fortune made from valuable patents was that of the late I. M. Singer, who left property valued at $9,000,000 in the United States and $4,000,000 in Europe. It has often been observed that inventors are not apt to amass wealth. This statement, however, is wide of the truth if it means that inventors are more apt to die poor men than those who engage in other branches of business. We are very confident, continues the *Artisan*, that if a comparison were instituted between inventors and all those in this country who have engaged in mercantile business, stock speculation, or banking, it would be found that as many inventors have acquired wealth in proportion to their whole number as those engaged in any other branch of business. We might enumerate instance upon instance where very large fortunes have been made, as in the case of Mr. Singer. Should we do this, however, we might supply an argument to those who believe that patents create oppressive monopolies. We are willing to grant that when wealthy rings and cliques are enabled to control legislation, so as to obtain the renewal of patents through the aid of bribes which they could not obtain under the regular working of the patent laws, oppressive monopolies may be created and fostered; but this is to be attributed to the general corruption of officials, and it is not peculiar to the working of the patent system. Designing individuals who combine to control legislation require monopolies of privileges in other departments of business which are more oppressive than any monopoly that has yet existed having for its basis a patented invention.

Deviation in the Compass.—The deviation of the compass on iron ships has been for a long time an important subject of scientific investigation. It is now suggested that some of the sudden and heretofore unaccountable changes in the deviation of the compass on such ships are the result of an unequal and varying diffusion of heat over the iron hull. These changes are often unsuspected until they are alleged as the cause of a vessel getting out of its course and running ashore. There have been sudden slight changes—not exceeding five degrees—noticed on board iron ships on the American coasts, and these are attributed to changes in the hull, caused by the vessel passing from cold to warm water, or the reverse, as, for example, into and out of the Gulf stream, or to the effect of the sun's rays striking on one side and then changed to the other.

Mine Drainage.

A paper on "The Development of Mechanical Appliances for the Drainage of Mines," by Stephen Holman, gives a comparison between the prevailing system of drainage in Cornish mines by the large Cornish pumping engines and the direct acting steam pumps, taking the "Special" as the pioneer, the representative of that class. After his introductory remarks Mr. Holman said that the matter resolved itself into a threefold question of cost, convenience and durability of the working conditions, whether permanent or temporary. He believed that the drainage of mines would inevitably devolve upon the simple, powerful and effective "Special" class. He gave in illustration a few examples of deep single lift engines, which had been placed in mines in most cases in pairs. A pair at Suffield colliery, 24 inch steam cylinder, 7-inch pump cylinder and 48 strokes per minute, raised each 10,000 gallons of water per hour in a single lift of 525 feet. A pair at Wigan, 30 inch steam cylinder, with 10-inch pump, at 48 strokes raised each 20,000 gallons of water per hour 500 feet. Two at Newcastle, 32-inch cylinder, 7-inch pump, 72 strokes per minute, each raised 10,000 gallons of water per hour, in a single lift of 1,068 feet. These were approximate statements of duty at 100 feet of piston speed per minute. At least 2,000 of these pumps are now at work in various British and foreign mines. The system of direct acting pumping engines was even more important, however, as affecting the drainage of new mining undertakings. For this purpose the "Special" pump was peculiarly fitted by its compact and complete character. One very important feature was that the direct acting steam pump of this type could be put down in pairs, whilst Cornish engines could not. Hence, whenever a mishap occurred, causing the stoppage of the engine, the whole of the pumping ceased, which of course was not the case when the engines were in duplicate.

Honduras Interoceanic Railway.

We publish the following on the authority of the *South West*, a paper published at Madisonville, Kentucky:

"We have had the pleasure of reading the report of Charles Seymour, Esq., chief engineer of the Honduras Interoceanic Railway, from which we learn that its Pacific terminus on the bay of Fonseca is readily reached by the Pacific Mail steamships from San Francisco, and that the bay affords an unsurpassed harbor. The line will pass from south to north, commencing on the Pacific, running through Honduras to its terminus on the Atlantic. Puerto Caballos is the Atlantic terminus; it has a good harbor, and 57 miles of the line running south from this point is constructed and in running order, now being used principally in transporting mahogany, rosewood, and dye timber to the sea board, which are found in abundance along its route, as well as hides and ores from the interior. The country abounds in gold, silver, and copper, and is well adapted to raising cattle, growing coffee, sugar, oranges, and all tropical fruits. The country is healthy, and can be easily reached from New Orleans; the distance from that point to Port Caballos is eleven hundred miles. We understand Mr. Seymour's plan is to run a steam propellor twice a month each way between these points, by which means close communication is opened between that part of our great grain producing region and Port Caballos, thus affording facilities to contractors to obtain supplies from our teeming country, as well as a large amount of negro labor. We trust this railway will be built, as it will be of immense advantage to the commerce of our Atlantic and Pacific States, as well as between Asia and Europe. It has advantages over any other route, from its harbor.

Consumption of Paper.—If it be admitted that the amount of paper used in a country furnishes an indication of its intellectual condition, the statistics put forth by Dr. Albiuns Rudal, of Vienna, are of singular interest and importance. On an average, according to him, the Russian uses one pound of paper a year, and the Spaniard one and one-half pounds, the Mexican two pounds within the same period, while under the same conditions in Italy and Austria the individual consumption of paper is at the rate of three and one half pounds each. The South American uses five and one-half pounds per year, the Frenchman seven and one-half pounds, the German eight pounds, the North American ten and one quarter pounds, and the Englishman eleven and one-half pounds. Dr. Rudal calculates that the paper produced in the whole world—paper of all kinds, of hemp, of linen, of straw, of jute, of rice etc.—amounts to 1,800,000,000 pounds. Half of all this quantity is employed for printing purposes, a sixth for writing purposes, and the remaining part for divers uses. The whole may be thus categorized: For government purposes 200,000,000 pounds are used; for instruction, 180,000,000; for commerce, 240,000,000; for industrial manufactures, 180,000,000; for private correspondence, 100,000,000; and for printing, 900,000,000. For the production of these 1,800,000,000 pounds of paper, there are 3,960 manufactories, employing 90,000 men and 180,000 women. In addition, 100,000 persons are engaged in collecting rags. At the present moment the United States imports only 3,000,000 pounds, local paper making amounting to 374,000,000 pounds—*Engineer*.

A Curious Problem in Motion.

Many of our readers have doubtless seen an experiment in which a ball held by a thread between the finger and thumb, which are kept perfectly still, is gradually set in motion, as is claimed, by the *will* of the person holding it. In most cases those who try the experiment do not consciously communicate any motion to the ball, and they honestly believe that it is set swinging by mere volition, or perhaps by some electrical action. The Academy of Sciences at Paris has been lately investigating this and kindred problems, and we find in French journals an abstract of an interesting paper on the subject, addressed to that learned body by M. Chevreul.

A celebrated professor of Strasbourg, Dr. Gerboin, has ascribed the oscillations to electricity, and has written a book in which he calls it "a new kind of electrical action." This idea is not a new one, having been advanced more than a century ago. Stephen Grey, F. R. S., who died in 1736, was celebrated in his time for his experiments on conductors of electricity. He passed the last years of his life in studying the ring hanging from the silken thread, under the firm impression that he could thus prove that the force by which the planets are made to revolve round the sun was of an electric nature. In one of his experiments he supposes himself in a position enabling him to see the equatorial zone. An iron ball, about an inch and a half in diameter, and feebly electrified, is placed in the center of a circular disk of resin about eight inches across; a light body hanging from a fine thread six inches long or thereabouts, held in the hand over the ball, *describes a circular curve from west to east*; if the disk of resin be elliptical, the light body will describe an elliptical curve! Dr. Mortimer, Secretary of the Royal Society, was of Gray's opinion; but Wheeler, who had aided the latter in several of his researches, declared that the desire of the experimenter to see his theory confirmed was the real cause of these motions. The dispute was continued after Gray's death; Priestly says they could arrive at no conclusion in the Royal Society, but that he thought Wheeler was in the right. M. Chevreul proceeds to say that his own experiments now confirm Wheeler's opinion, and then lays down this principle: "That there are motions which our muscles impart to bodies without our being conscious of them, provided we think those motions possible; moreover, our eyes, *when open*, being disposed to follow them, hence the direction of the motion, which therefore takes place in consequence of our *thought*, which is not our *will*, and of an exterior accidental cause which operates on our sight."

The abstract of M. Chevreul's paper which we have seen was brief and in a popular journal, but his explanation as reported appears to be the correct one. The subject is curious and interesting, and we may refer to it again.

The New York City Fire Department.

This useful body now consists of 734 men, divided into sixty-seven companies, among which are forty-two steam fire-engine companies, seventeen hook and ladder companies, and six chemical engine companies, and a fire steamer for blowing steam into a fire. To be secure against accidental derangements, there are nine spare steam fire-engines, two hook and ladder trucks, and four tenders always ready for use. Besides this there are in the newly annexed wards in Westchester county, two steam fire-engine companies, two hook and ladder companies and four chemical engine companies; on Blackwell's island, one steam fire-engine, two hand engines and one chemical engine; on Ward's island the same, and on Randall's island and at the Catholic Protectory a hand engine each, with other apparatus.

The manner in which these bodies operate in the city is as follows: The city is divided into ten sections, with a battalion commander for each. Each captain of a company is responsible for the perfect working of the telegraph alarm boxes and fire hydrants in his district. Patrol duty is performed day and night, a few men being permanently at each company's quarters, who keep the water in the steam-boilers hot by means of a gas arrangement, and everything else always ready to start at once when an alarm is sounded by means of the telegraph, and in this way the surprising promptness is attained which is so often admired, and most of the fires suppressed in their incipient state.

The result is that while with the increase of population and property, the number of fires has been continually increasing, the total losses have during late years been greatly reduced; thus in 1871 there were 1,258 fires, with a loss of $2,127,000, while during the last year, ending June 1st, 1875, there were 1,518 fires, with a loss of $1,820,000. A corps of sappers and miners has lately been organized and trained in the use of explosives.

But the most creditable item in regard to this institution is its financial management; while the appropriation for this year was $1,316,000, not much more than half this sum had been used when two-thirds of the year had elapsed. When we consider the vast amount of labor, the addition of numerous new engines and liberal supplies, also the usefulness of this department, the amount of money it costs must be deemed to be very moderate and a wise and profitable investment. — *Manufacturer and Builder*.

Good Health.

Are New Houses Safe?

It is a very general opinion that a long time is needed for a newly built house to become thoroughly dry, and that it is not safe to live in one for several months (some say a year) after it is built. Popular opinions have generally some foundation, and I am anxious to know whether this opinion is correct, or how far it is correct.

I have shares in two associations formed to provide better and more wholesome dwellings, especially for the working classes, and I hope we have succeeded, for the death rate amongst our tenants is considerably below the average, partly owing, no doubt, to our tenants being generally of sober and steady habits, for we value peace and quietness, and so do they. We let our houses very soon after they are finished, and in reply to my inquiries I am told that the inmates of the newly built houses are quite as healthy as the others. We have taken unusual care to have every room well ventilated, which may account for the absence of apparent injury from damp, but I am not quite satisfied that we are acting prudently. I should like to be advised, if we are not, by those of wider experience.

The dampness of walls arises not only or chiefly from the water absorbed, but rather from that combined with the lime in the form of hydrate used for mortar and plaster. This combined water is displaced by carbonic acid, absolutely converting the hydrate of lime into carbonate, and it has been suggested that this change should be hastened, so that the houses may become dry more quickly by keeping the rooms filled with carbonic acid by burning coke or charcoal in them so as to fill the rooms with their fumes. This sounds feasible, but is there no danger of the conversion of the hydrate into carbonate being too rapid, and the result being a product more resembling friable chalk than hard limestone? What is done too quickly is not done well. Is this change done too quickly to be done well?

I am inclined to believe that the experience of our two associations proves that it is possible to avoid danger from the dampness of new houses by passing air through them rapidly enough to prevent its becoming saturated with moisture. Air which contains no watery vapor is neither pleasant nor wholesome. It should be about two-thirds saturated, and if this proportion be not much exceeded no injury can arise from such vapor only, and there seems no reason why, if it be derived from a damp well, it should be injurious if not in excess—*i. e.*, if the air be changed rapidly enough to prevent it becoming damp.—*Ex.*

Force and Stimulants.—The London *Lancet* remarks that at the present day our treatment has assumed a character too decidedly stimulant and not quite sufficiently nutritive. Stimulants ought to be regarded as auxiliaries to nutrition more than they are at present. Nutritive material, as milk, meat juice, eggs, and various forms of starch, ought to form a greater matter in the dietary of the sick than stimulants, whether nitrogenized or alcoholic; such materials, when assimilated, give supplies of force. Stimulants may assist in their assimilation, and do so; but in themselves stimulants only furnish limited supplies of force-bearing material. They are, however, a means by which the system may reach some of its physiological reserve fund. Such use may be advantageous or pernicious, according to circumstances; and an ill-regulated or excessive process of stimulation may give results as disastrous as a wise and intelligent resort to stimulants may be beneficial and preservative in its consequences.

Beef Extract for Invalids.—To half a pound of beef or fowl recently killed, and chopped fine, add one pint of cold boiled water, to which four drops of hydrochloric acid and one-eighth ounce common salt should also be added. After the mixture has stood an hour, throw it upon a hair sieve, or piece of muslin, allowing it to drain without pressure. The first portion passing is usually turbid, and must be returned to the sieve until it runs clear. When all the liquor has been drained off, gently pour one-fourth pint of water, in small lots at a time, upon the residual minced flesh, allowing it to run into the liquid collected. In this way will be obtained about three-fourths of a pint of cold extract of flesh, of a red color, and of a pleasant, soup-like taste. Dose, one teacupful at a time, cold. It must not be warmed, and should be prepared fresh every twelve hours, as heat will cause decomposition and the separation of a solid mass of coagulated albumen.

Striped Stockings.—Ladies who are in the habit of wearing striped stockings—a style which appears to be fast coming into fashion—should be careful about the coloring substance. A case was reported in London in which an external inflammation of the feet had been produced by wearing stockings striped with orange red. The subject was Mr. Hart Dyke, and the dye-stuff coralline.

Dr. Carpenter is inclined to believe that a purely vegetable diet, if it contains a due proportion of oleaginous matter, is capable of maintaining the physical powers of the body at their highest natural elevation, even under exposure to the extreme of cold.

Carbonic Acid in the Lungs.

This question is considered by a cotemporary as follows: Neither carbonic acid nor the other products of our respiration are injurious to us unless breathed in excessive proportion, for they are constantly present in our lungs and in the air that enters them. The air we expire is only a small part of that which our lungs contain, and a large part of that which leaves our lungs remains in the trachea and air passages to be mixed with and to warm the fresh air inspired. Though we cannot live long in air containing above three per cent. of carbonic acid, that in our lungs contains a far greater proportion of it mixed with the other products of respiration; and birds or beasts that sleep with their hills or noses covered, must inspire some small portion of the air they have previously expired, and it is no doubt good for them that they should do so, just as it is good for us that the air we inspire should mingle with that which, though it has left the lungs, remains in the air passages. Such facts distinctly show that the presence of carbonic acid in our lungs is not hurtful, for it is always there, and also that we can breathe again a part of the air we have once breathed, for we always do so.

What, then, is the reasonable explanation of the depression we feel and the injury we sometimes suffer from breathing air mingled with a little of that which has been breathed by ourselves in men even *in good health* some little time before? Is it not that the organic matter contained in the expired undergoes very rapid changes, and that, though it is not immediately, it very soon becomes injurious unless it be very widely diffused. It is by some believed that actual fever can be produced by overcrowding, filth and bad ventilation. Except by zymotic germs proceeding from a case of fever, it would, however, be rash in the extreme to rely on such a doctrine, for feverish disturbance is constantly being produced by want of fresh air alone, and not a few instances of typhus have, at least apparently, arisen from the same cause, combined with overcrowding, without previously existing disease. Of course, when disease is present, whether the hypothetical zymotic germs be a reality or not, free ventilation is pre-eminently needed, and experience has amply proved that that, together with scrupulous cleanliness, is the most effective preventive of disease, just as cleanliness rarely fails to keep away the itch and lice, the first of which probably, and the last certainly, derive their *immediate* origin from living organisms. Dirty people suffer much from personal vermin, and those only who breathe dirty air, including in that, air rendered foul by pulmonary and cutaneous perspiration, are in any great danger from fever.

Anæsthesia Two Centuries Ago.—The practice of anæsthesia in ancient surgery is referred to by Middleton, the old dramatist, 1657, thus:

"I'll imitate the pities of old surgeons
To this lost limb, who, ere they show their art,
Cast one asleep, then cut the diseased part."

Dr. Hager recommends the use of the following powder for excessive sweating of the feet: Burnt alum, five parts; salicylic acid, two and a half parts; wheat starch, fifteen parts; Venetian talc, fifty parts; mix and make a very fine powder.

Useful Information.

Peanut Oil.

The rapid extension of the cultivation of peanuts in North Carolina, Virginia, Tennessee, Georgia and South Carolina is due to the use now made of them for the oil they contain. According to official agricultural reports, previous to the year 1860 the whole crop aggregated only 150,000 bushels per annum, grown principally in North Carolina; last season's product reached 2,000,000 bushels, valued at $3,000,000. In a commercial point of view the oil is of much more importance than the nuts themselves. The oil is in large demand, and answers for many purposes as a substitute for olive and almond oils; it keeps a long time without becoming rancid. The amount of oil contained in the nut varies according to latitude and other favorable conditions and circumstances, and is proportionately large.

All the oil comes from the "meat," the husk being of no value. The oil is extracted by pressure, and the pressed cake is used both as food for cattle and as manure. Algiers also supplies the port of Marseilles with large quantities of these nuts, from which the oil is expressed, and probably destined to augment the supply of the olive oil for which that city is so great a market. The production of peanut oil in the United States dates back to the war, when it was used to a large extent for table purposes in the South, olive oil being almost unobtainable; it was also used quite generally at that time as a substitute for lard. The cake residuum was made serviceable also; after being roasted and ground it was used in place of coffee and chocolate, making a tolerable, if not a desirable beverage.

Straw matting is most readily washed with a cloth dampened with salt water. Indian meal sprinkled over it and thoroughly swept off will also clean it pretty thoroughly.

Explosive Prescriptions.

The following bits of "useful information" seem to show that our common toilet article of glycerine is a dangerous substance to deal with when compounded. Nitro-glycerine is not its only explosive compound:

The *Pharmaceutical Journal*, of Vienna, states that the following prescription was sent to a pharmacist: "Chromic acid, eight grains; glycerine, one drachm. For external use." The dispenser dissolved the acid with a little water in the phial by a slight shaking; the glycerine was then poured in, and the phial again shaken. Thereupon the compound exploded with a very loud report, and was projected with force to the ceiling of the shop. The phial, which did not break, became coated with a black pigment, and remained in the hand of the frightened dispenser. The case deserves attention from the fact that the ingredients were in such small quantities and the explosion so powerful.

Curious Action of Glycerine Upon Borax.

Following is another instance of a similar nature, as narrated by Mr. F. Long in the *British Medical Journal:* "I had occasion to make an alkaline lotion a short time ago, which consisted of borax, bicarbonate of soda, chlorate of potash, glycerine and water. After the ingredients were put in end the bottle filled with water, I added half an ounce of glycerine and corked the bottle. To my surprise, in a few seconds violent action began to take place, and I was obliged to remove the cork for fear of an explosion. I could not understand what had taken place, and could only think that there was some acidity in the glycerine. But such was not the case—it was perfectly neutral to test-paper; and the other chemicals, I believe, were perfectly pure. I then repeated the experiment in the following way, and a very interesting one it was, perfectly inexplicable to me, and of which I can gather no information from any work. I put into a test-tube about equal parts of powdered borax and bicarbonate of soda; I then added some glycerine, which of course sank through the solution of soda, and rested over the borax; chemical action immediately began, the glycerine immediately became dissipated, and the borax was dissolved. I have repeated the experiment several times, and have obtained the same result with the carbonate, although not to the same amount. The change is evidently at the expense of the glycerine; for if only a few drops be added the action soon stops, to be renewed with greater intensity if a larger quantity be then added. I am not a sufficient chemist to unravel the decomposition."

The Restoration of Strasbourg Cathedral.—A letter from Strasbourg to the *Industriel Alsacien*, of Mulhausen, says, "The repairing of the damages caused by the bombardment to the cathedral has been going on for three years, and is yet far from completion. The injury done is incalculable, the fragments of the bombs having penetrated to every part of the building. The restoration of the nave and the replacing of the whole roof occupied two years, and the last year has been spent in repairing the tower and the spire, the straightening of the part of which, from a height of 350 feet upwards, is one of the boldest architectural feats of our day. The architect estimates that more than a year will yet be required to restore the magnificent structure to its former perfection."

Transferring Pictures.—Pictures may be transferred to painted surfaces in the following manner: Cover the ground with an even coat of light colored carriage varnish, which should be allowed to set (nearly as dry as if for gilding). If the print to be transferred be colored, soak it in salt and water; if not colored, use water alone. Remove superfluous water by pressing between blotting pads, and then place the picture face down upon the varnish, pressing it smooth. When the varnish is dry, dampen the paper and rub it off with the finger. The picture will be found upon the varnish, and another coat of the latter should be added to bring out the effect. This process answers equally well for glass or metal surfaces.

A New Method of Marking Tools.—Much trouble can often be saved by marking tools with their owners' names, which can easily be done in the following manner: Coat the tools with a thin layer of wax or hard tallow, by first warming the steel and rubbing on the wax warm until it flows, and let it cool. When hard, mark the name through the wax with a graver, and apply nitric acid; after a few moments wash off the acid, and wipe with a soft rag, when the letters will be etched into the steel.

Purifying Gas.—The experiments which have been recently made at the joint expense of three of the principal gas companies of London, and conducted by Mr. Vernon Harcourt and Dr. Siemens, in order to ascertain the best means of eliminating sulphur impurities from gas, have failed to be immediately productive of any practical result, and have been discontinued. The experiments were estimated to cost between £500 and £600, but they have exceeded an outlay of £3,000.

To fix labels on tin, use French polish or a solution of shellac in naphtha or alcohol.

Domestic Economy.

Rye—How to Cook and Eat It.

Rye is not as much grown as of yore, yet it is a staple product in many localities, and the following receipts for rye cookery, contributed to a late number of *Science of Health* by Miss Julia Colman, will prove of interest and value to many readers;

Rye Gems.

Take ice cold water, as for wheat gems, and stir in good rye meal, entirely unbolted, sifting with one hand, stirring with the other, until they are of a consistency much thicker than that required for wheat. Experiment with a few at first, making some thicker than the others (the last about as thick as you can well stir them), so as to be sure to get the right consistency before making them for the table. Then bake them a little more than you would wheat, and serve warm or cold as you prefer. We like them warm.

Rye and Wheat Gems.

Those who do not fancy so much of the rye taste, may soften it a little by putting in one-third wheat and then making them into gems, precisely as for wheat or rye alone, making them not quite so thick as the latter.

Rye and Indian Gems.

These are made very much like the rye gems, only one-fourth of the meal should be corn meal, of medium fineness. It does very well without scalding, though in that case it should be baked very thoroughly. If scalded, it should be mixed so thick that the gems need to be smoothed with a wet spoon before putting them into the oven. Otherwise they will seem soft and mushy. If rather soft, let them stand some minutes after they are out of the oven before serving them. This will do them more good than trying to bake them in the oven.

Rye and Indian Loaf.

Take two quarts of coarse corn meal, wet it thoroughly with two quarts of boiling water, add two quarts of rye meal, mix intimately, make into a loaf three or four inches deep, or, if convenient, put into Boston brown bread pans, place on top of the stove, where it is barely hot enough to make it simmer, let it stand here until it cracks well over the surface, say an hour and a half or two hours. Then put into a hot oven, bake two or three hours, according to the size of the loaf, then cool the oven gradually, or take a loaf out and steam it an hour or two.

Rye Mush.

If the rye meal or rye Graham be coarse, sift it into boiling water with one hand, stirring with the other. If it be fine, pour the meal into boiling water and stir vigorously until thoroughly wetted and of the consistency you wish it when done. Then in either case, cover close and set it where it will cook slowly, from forty to sixty minutes or more. Dates may be added to this if desired, stoning them and stirring them in just before serving. Dress the plain mush with stewed currant.

Rye and Indian Mush.

Use two parts rather coarse corn meal and one part rye meal, stirring in the corn meal first and cooking a while if desired, then adding the rye meal, stirring very carefully, then cover close and cook slowly one hour or more.

Rye and Rice Mush.

Boil one pint of rice in three quarts of water for three minutes, then add coarse or fine rye Graham as above, and cook one hour.

Vienna Yeast.—The Vienna bread is reputed to be the best in the world. It is said to owe its superiority to the peculiar yeast employed, which is also used in the manufacture of the celebrated Vienna beer. This Viennese yeast, according to the London *Chemist and Druggist*, is prepared in the following way: Three kinds of grain, namely, Indian corn, barley, and rye (all sprouting), are powdered and mixed, and then macerated in water at a temperature of 65° to 75° C. In a few hours saccharification occurs. The liquor is then racked off and allowed to clear, and alcoholic fermentation is set up by the help of a minute quantity of yeast. As fermentation progresses the globules of yeast reproduce themselves by a species of budding, engendering at first very small globules, but these rapidly increase in size. Carbonic acid is disengaged during the process with so much rapidity that globules of yeast are thrown up by the gas, and remain floating on the surface, where they form a thick scum. This scum is carefully removed, and constitutes the best and purest yeast. When drained and compressed by a hydraulic press, it can be kept from eight to fifteen days, according to the season.

Harlequin Jelly.—With the extra refined gelatine, make a gallon of clear jelly; color with various fruit dyes. The juice extracted from spinach leaves will give a fine green; cochineal, red; the zest of orange, rubbed on crystal sugar, yellow. These, with various colors from fruit jellies, will afford a number of hues. Have a large mold, into which put the various colored jellies in an almost solid state, to prevent their mingling. When full, set the mold aside until perfectly set, then turn it out on a glass dish, when the various colors will be found tastefully blended and marbled. These variegated dishes are very ornamental to the table.

MINING AND SCIENTIFIC PRESS.

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, W. B. EWER, GEO. H. STRONG JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week.	1 month.	3 months.	1 year.
Per line.....	.25	.80	$2.00	$5.00
One-half inch.....	$1.00	3.00	7.50	24.00
One inch.....	1.50	4.00	12.00	40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

San Francisco:

Saturday Morning, Oct. 23, 1875

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Enameled Water Pipe; Giant Powder, 257. Award of Premiums at the Mechanics' Fair; A New Feature of the Comstock Lode; Notices of Recent Patents, 264. Improvement in Saw Teeth and Matching Knives; Saving Gold from Sulphurets; The Concentrating Works at Falun, Sweden, 265–6. Academy of Sciences; Patents and Inventions, 268.

ILLUSTRATIONS.—National Tube Works, Boston, Mass.; National Tube Works, M'Keesport, Pa., 257. Randolph's Patent Lip Saw Teeth and Matching Knives, 265.

CORRESPONDENCE.—Eastern and Central Nevada—The Mines of the Tybo and Reveille Districts, 258.

SCIENTIFIC PROGRESS.—Constitution of the Sun; Magnetism; Gender in the Hemp Plant; Testing Oils by Electricity; An Interesting Electrical Experiment; Ocular Incquality; Earthquake Investigations; Effects of Electricity on Plants; Hygroscopic Paper; To Preserve Metallic Sodium, 259.

MECHANICAL PROGRESS.—Production of Bessemer Steel in the United States; New Mode of Raising Sunken Ships; Pernot-Martin Furnace; Multiple Engines; Economy in Furnace Heating; Punching Boiler Plates, 259.

MINING SUMMARY from various counties in California, Nevada and Washington Territory, 260–1.

USEFUL INFORMATION.—Peanut Oil; Explosive Prescriptions; The Restoration of Strasbourg Cathedral; Transferring Pictures; A New Method of Marking Tools; Purifying Gas, 263.

GOOD HEALTH.—Are New Houses Safe? Force and Stimulants; Beef Extract for Invalids; Striped Stockings; Carbonic Acid in the Lungs; Anæsthesia Two Centuries Ago, 263.

DOMESTIC ECONOMY.—Rye—How to Cook and Eat It; Vienna Yeast; Harlequin Jelly, 263.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 268.

MISCELLANEOUS.—Toughened Glass: Engineering Feat; A New Self-Acting Saloon; Kid Glove Making in France; Navigating Torpedoes; Manufacture of Machine Paper-Hangings; A Water Motor, 258. The War Ship of the Future; Russian Way of Stopping Holes in Ships; Interesting Object for Experiment; An Old Georgia Silver Mine; Deviation in the Compass; Mine Drainage; Honduras Interoceanic Railway; Consumption of Paper; A Curious Problem in Motion; The New York City Fire Department, 262.

Award of Premiums at the Mechanics Fair.

The following ie a list of awards made hy the committees of the Mechanics' Institnte Fair, in addition to those given in our issue of last week:

SILVER MEDALS.

San Francisco Plating Works: For Plated Ware.
D Tisch: Best display of Foliage Plants.
Mrs A C Cook: Best Preserved Flowers, Oakland.
Pacific Copper Works: Soda Generator, first premium.
Geo H Tay & Co: Best California Made Stove Castings.
Bowen Bros: Best General Exhibit of Groceries.

DIPLOMAS.

C Gulttard: Best Chocolate, first premium.
Ghiradelli & Co: Coffee and Spices, first premium.
J Vogeley & Bros: Best Fancy Candies, first premium.
C C Burr & Co: Mustard and Spices.
California Italian Paste Company: Maccaroni Paste and Farina, first premium.
J Johnson: California Made Starch, first premium.
Aldeu Fruit Company: Dried Vegetables, first premium.
C Newman: For Patent Covered Demijohn.
Emily R Eastman: Largest exhibit of Painted Photographs.
John F Snow: Best display of Cleaued and Dyed Goods.
Dexter & Co: Bon Bons, first premium.
Painter & Co: Printers' Material, first premium.
John Newman and Bennett, Soda Fountains, first premium.
Henry Marsh: Brass Musical Instrument, first premium.
B Bendel: California Made Matches, first premium.
Chenery, Souther & Co: Green Ginger Brandy.
D Mecarini: Plaster-Work, first premium.
Miss E A Rockwell: Miniature Painted in Oil.
Savage & Son: Cast Iron Work.
Swan Brewery: Best exhibit of California Ale and Porter, first premium.
N Seibert: For Lubricator, first premium.
C O Farciot: Hanger.
Saulbach: Boiler Protector.
August Lisewski, aged 18 years: For Ingenuity in Making a Piano.

CERTIFICATES OF MERIT.

Mrs M Williams: Worsted Work.
Miss Mary Condon: Spatter Work.
Miss Hillpish: Colored Wax Flowers.
Mrs C E B Howe: Group of California Pioneers (Photograph.)
Natban Joseph: Exhibit of Cutlery.
E A Knowland: Feather Work.

A New Feature of the Comstock Lode.

At the meeting of the California Academy of Sciencee last Monday evening, the following interesting paper, entitled "Notes on a New Feature of the Comstock Lode," was read by Dr. G. F. Becker, of the Univereity of California:

It is well known to those who have had occasion to make themselves familiar with the Comstock lode, that throughout that portion of the vein which lies in Virginia City, the west or foot wall is a continuation of Mt. Davidson; aud consists, like the mass of that mountain, of syenite; while the east wall is a porphyry, more nearly described as a trachytic greenstone, or propy'ite. The direction of the fissure subsequeutly filled by the vein matter of the Comstock, was plainly determined hy the previously existing surface of contact between syenite and propylite, which naturally offered less resietance to rupture than the solid maes of either adjoining rock. This is clear from the fact that for over a thousand feet from the surface, only insignificent masses of either rock were found on the side of the vein opposite to that of which they are especially characteristic. So strong was the influence of the direction, both in strike and iu dip, given to the fissnre hy the presence of this comparatively weak surface of oontact in the rocky mass, that the fissure extending in hoth directions away from Mt. Davidson into solid propylite, unaccompanied hy syenite, retained the strike (nearly north aud south) and the dip (from 35° to 50°) of the Virginia portion, almost unaltered.

This very clearly defined influence of the contact snrface, was of itself good reason for snpposing that the fissure in Virginia must follow the dividing plain between syenite aud propylite to a very considerahle depth, and not improhahly to one heyond the reach of mining operations. Nevertheless, although the snbject has been very wisely left in abeyance hy the geologiste who have publicly discussed the Comstock, it cannot have escaped any of them that the fissure could not indefinitely follow this contact; for the propylite is recognized hy them as a volcanic rock which has overflowed the older syenite, and therefore, nnless we should make the highly improbable assnmption that the syenite, (which in Virginia is plutonic), the propylite and the vein matter eminated snccessively from a siugle fiesure in the earth's crnst, a lowest point in the contact between the underlying syenite and the overlying propylite must eventually occur, from which the fissure would naturally descend towarde the seat of the force by which it was caused. From the moet depressed point in the contact surface, the fissure would pass into the underlying, or syenite rock, and doubtless out of it further below, into whatever may nnderlie it in its tnrn.

From the point where the fissure leaves the contact between the two species of rock, its dip would in all probability be controlled hy circnmetances very differnt from those which decided it in the portion lying near the croppinge; for, from the point at which the fissure forming shock impinged upon the lower surface of the syenite, the fracture must have followed the direction of least resistance, or presumahly a straight line, and the shortest line from the point in which the subterranean force encountered the syenite, to the nppper surface of that formation; and a moment's thought will serve to show, that apart from local nnd altogether incalculable irregularities iu the lower snrface of the rock, this line could continue in even approximately the direction of the present dip, only in case the syenite not only formed a coue above the general level of the country, but filled n vast depression helow it as well. The passage of the lode into the syenite would therefore naturally be accompanied hy a change in dip, towards the perpendicular.

In May last I made observations, repeated aud extended in August, which seem to establish beyond question the hitherto unnoticed fact that the lower workings of tho miues in Virginia City have reached the point at which the fissure passes from the contact surface between the syenite of Mt. Davidson and the country porphyry, (propylite,) into the underlying syenite. The depth below the surface at which this change occnrs, is not very far from 1,500 feet.

This statement is hased upon the following obscrved facts: In the Chollar-Potosi mine, the north and south drift on the 1,150-ft level, ehowe a wall of syenite for a distance of sevenl hundred feet, which is considered in the mine to be the true east wall. The rock is very solid in charaoter, exhibiting none of the evidences of dynamical action commonly seen iu inclnded rock, or horses. The wall is accompanied by clay seams.

In the Hale & Norcross an unhroken mass of syenite lying east of tho vein is exposed, to a thickness of 110 feet, hy the cross-cut from tho station on the 2,100 foot level. The croes-cut from the 2,200 foot station bad advanced on August 20th to a distance of 100 feet from the shaft. For the whole of this distance the dr ft was in solid syenite, and the face showed no signs of the proximity of the vein. The hottom of the incline, 2,230 feet below the surface, as well as its whole lower portion for a distance of several hundred feet, is in unhroken syenite. The syenite is said to have heen struck as high as the 1,200 foot level. The dip of the vein is rapidly increasing in the lower levels of this mine, which accounts for the distance of the incline stations from the east, or hanging wall of the lode.

In the Savage the incline shaft has heen from at least as high as the 1,900 foot level to its present depth of 2,280 feet in solid syenite. From the 2,100 foot station, ahout 200 feet of syenite was paesed through hefore the vein was renched, and on the 2,200 foot a still greater thickness. This syenite is plainly the same hody struck in the Hale & Norcross, 600 feet distant, and in the Chollar-Potosi, 1,000 feet further south. The dip of the vein in the Snvage is rapidly increasing in the lower levels.

In the Gould & Curry the east wall is inaccessible, but a large body of syenite is found withiu the vein, and the main "horse" rock of the mine in the lower levels (1,500 and 1,600 feet,) is syenite. Although an inspection of the east country rock in this mine would he much more satisfactory than an inference, it seems to me fair to conclude that had the comparatively soft and hrittle propylite porphyry formed the east wall, the main inoluded rock would have been of that species.

In the Best & Belcher and the Consolidated Virginia, too, the east clay seams have not been pierced for fear of tapping a water hody, but the included rock on the 1,500 foot and on the 1,565 foot levels of the Consolidated Virginia, where not too much decomposed for recognition, is generally syenite.

In the California, the third oross-cut on the 1,500 foot level has been run into the east country, which proves to he syenite of the solidest description. This wall seems to be very nearly perpendicular.

In the Ophir, syenite has been struck at several points on the 1,465 foot level to the east of the vein, and near the south line has been penetrated to a depth of three hundred feet; on the 1,708 foot level an east wall of syenite has been opened up for some 600 feet in the direction of the vein, and hae been penetrated to the east to a distance of over 200 feet. The walls of the vein in the Ophir in the lowest levels are nearly perpendicular.

From the above it appears that for over a mile, the east wall of the lode on the lower levels, wherever struck, is eyenite; that in the mines hetween the Ophir and the Chollar-Potosi, where the east wall has not been reached, good grounds exist for inferring the existence of syenite to the east of the vein; that although the syenite hae been pierced in a number of places to a distance of several hundred feet, both horizontally and perpendionlarly, no other formation has been reached, nor any indication that its limits have been approached; on the contrary, this eastern syenite is apparently ae solid as Mt. Davidson itself. The tough and comparatively undecomposed condition of this syenite as contrasted with the porphyry, is deserving of epecial remark. It further appears that where the relations between the vein and the walls of the fissure have been most completely exposed, the occurrence of syenite on the east wall is accompanied by a very decided increase in the angle of dip.

I therefore conclude, that throughout the Virginia section, the point has been reached at which the Comstock enters the syenite.

The Gold Hill mines seem nowhere to have reached the syenite, as was to he expected, since from the conformation of the country, the syenite, if it underlies the porphyry in Gold Hill as well as in Virginia, will probahly be met with only at a much greater depth.

To establish the exact line of the paesage of the vein from the propylite into the syenite, would of course require a epecially authorized examination of the mines, since n majority of pointe in which the east wall has been struck are hidden from view, either hy the closure of drifts no longer essential to the working of the mines, or hy lagging in the shafts, etc.

Many important deductions, were this the place for them, might be hased npon a ohange in the conditions of the Comstock lode, which must he fraught with exceedingly important consequences to the greatest mining interest of the Pacific coast; hut I prefer to confine myself to submitting to you the fact of this remarkable, and at this time most unexpected alteration in tho character of the vein.

WORKMEN are busy grading the foundation for the large engine in Griffith's stone cutting works at Penryn. Part of the machinery is on the ground, and extensive additions are being made to the works.

MR. ELISHA RANSOM, of the firm of W. A. Holcomb & Co., grain merchants in this city, was shot and severely injured hy a burglar whom he discovered in his house, a few evenings since.

AT their last quarterly meeting the San Francisco Chamber of Commerce refused to do away with "collection day."

Two Chinese residents of Marysville were murdered by a drunken man on Wednesday last.

VERY damaging floods have occured in England within the past few days.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

IMPROVEMENT IN ENDLESS ROPE TRACTION RAILWAYS.—A. S. Hallidie, San Francisco. This is an improvement in that class of railways in which an endless wire rope, moving in an underground tube, is used for propelling the car nlong the track. In this class of railwaye, a gripping device which is secured upon the car, has a shank passing down through a slot in the upper side of the tnhe, and to the lower end of which, inside of the tube, the gripping jaws are arranged to grip the rope. This invention relates, first, to an improved device for closing the elot in order to prevent it from becoming clogged by the lodgment of foreign substances in it, and to prevent the wheels of vehicles from dropping into it; and secondly, to an improved pulley for supporting and guiding the rope where it changes its direction at the top and bottom of an incline.

DEVICE FOR CUTTING PRINTERS' LEADS.—J. A. T. Overend. This is an improved machine for cutting the epacing leads nsed hy printers into lengths for the different kinds of work required; it consists in the employment of an angularly placed table upon which the leads are supported by a slight projection extending hack from the cutter on one side. Upon the opposite side is an adjnstable stop in line with the lead, and this determines ite length. The cutter is mounted upon a projecting lug, and operatee through a elot in the table, and as the leads are cut off they elide down the inclined face of the table, so ae to be out of the way. The face of the cutter lever, when it moves against the lug, is chambered, and this gives the advantage of a rim heating, which ensures perfect steadiness, and also n chamber for oil.

PAINT COMPOUND.—I. L. Merrell, San Francisco, California. This invention relates to an improved paint iugredient and compouud. The ingredient which the inventor adds to paint compounds is pulverized and finely ground soapstone (steatite.) This substance, when added to ordinary lead or othor mixed paint, will give it a heavy hody and greatly improve its durability, while it does not interfere with its flowing quality, while heing laid on with the brush. It also renders the paint, to a certain extent, fire-proof. The inventor prepares a special mixture for paint, in which the substance is used.

TYPE CASTING MACHINE.—J. A. T. Overend, San Francisco. The object of this invention is to provide a machine for casting movable type and then conveying them directly from the matrix and mold to another part of the mechanism, by which the type are hrokon from the stem, and rubhed or cleaned, and emoothed of any irregular projecting edges which may have been formed in casting. The whole operation being continuous and requiring no power but that required to drive the machine.

MUSIC LEAF TURNER AND HOLDER.—George L. Dampfel, Benicia, California. Thie is a very ingeuious piece of mechanism, to be employed in turning the leaves of hooks or loose music, while the performer is playing, without stopping or ueing the hands; there is also a device for holding such looee leaves in place while they are being turned. A detailed description of the invention would hardly be understood without the aid of an engraving.

IMPROVED FAUCET.—Wm. C. Bussey, San Francisco. The object of this invention is to provide a faucet for drawing liquids from harrels, casks and other vessels, through which the liquid can he drawn, and its flow regulated, without the employment of a rotating plug or epigot, thus not only providing a cheaply manfactnred faucet bnt one which will have no joint to wear and leak. The faucet can be made of either wood, metal, or other material.

A WASHINGTON dispatch etates that in the United States supreme court, case No. 673, United States appeals *vs.* Barbara Soto, *et al.*, appeal from the district court of the United States for the district of California, on motion of M. Bean, it was ordered by the court that the appenl in this cause be docketed and dismissed. No. 74 United States appeal *vs.* Jose Antonio Estudillo, appeal from the district court of the United States for the district of California, on motion of M. Blair, ordered by the court that the appeal in this cause he docketed and dismissed.

A NEW steamer of the Inman line has made the trip from New York to Queenetown in seven days, fifteen hours and forty-eight minutes, which ie alleged to be the shortest time port to port ever made across the Atlantic in either direction.

A LONNON telegram announces the death of Sir Charles Wheatstone, who ie claimed hy many to he the inventor of the electric telegraph, and Professor of Experimental Philosophy in King's College.

IT is reported that the Pacific Mail company have sold their wooden side-wheel steamers on the Japaneee waters for local trade. The amount realized is said to he $800,000.

Improvement in Saw Teeth and Matching Knives.

The accompanying engraving represents a segment of a saw plate, provided with the Randolph patent lip teeth, the solid tooth having one lip, and the inserted tooth two lips. It also represents two matching knives, to be used with cutter heads (the knife for cutting the groove, and one of the knives for cutting the tongue) in making flooring, ceiling, etc.

The main features in the construction of these teeth and these knives consist in constructing them with a cutting lip, or lips, and giving the whole a forward curve, so that they cut the lumber instead of tearing or scraping it, the cutting edges of the teeth, or knives, as the case may be, being in the same plane with the cutting edges of their respective lips, and radial, or nearly so, to the center of the saw plate or cutter head. The advantages claimed for this saw tooth over any other tooth in use, as demonstrated by actual tests made near this city, are:

First. A saw provided with these teeth requires but two-thirds the power to drive it that is required to drive the same saw provided with any other teeth in use, and as a consequence will carry one third more feed and will cut one-third more lumber with the same power in the same space of time.

Second. These teeth cut the lumber smoothly and therefore can cut a much less kerf than any other teeth in use, making at least seven boards where other teeth would make but six boards from the same timber; or, in other words, making from the same timber seven thousand feet of lumber, where any other teeth in use would make only six thousand feet.

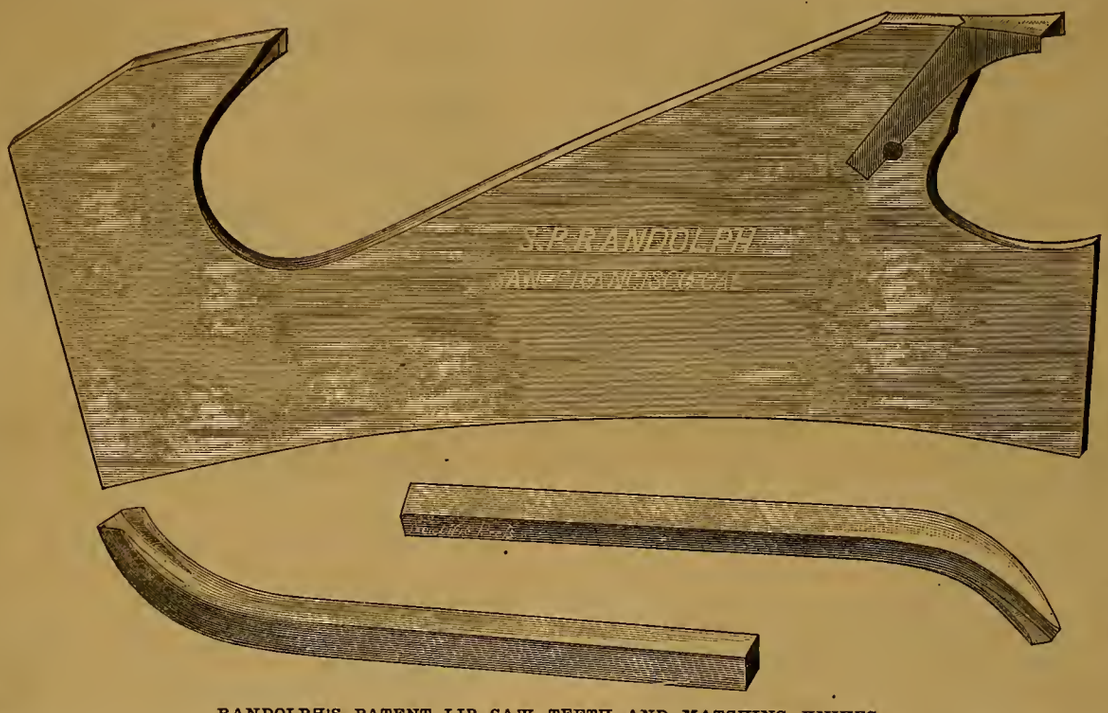
Third. The teeth require sharpening only once in four or five days, and if kept out of gravel, then only a little on the inside (never on the outside), with a small file, and need not be removed from the said plate till worn out, retaining their width without any perceptible depreciation, cutting a uniformly even kerf, and the lumber of even thickness without any change of the set-works.

The advantages claimed for the Randolph patent matching knives are: That after once set properly in the cutter heads, they need never be removed therefrom till worn out, requiring no sharpening except a very slight dressing on the inside once in about five or six days with a small file, retaining their full width until worn out. It is claimed by actual demonstration a set of these knives will run for three months without being removed from the cutter head, and that the flooring or ceiling made the first month will match that made the last month perfectly, a result which cannot be obtained with the ordinary matching cutters, because the wear upon them reduces their width, so that the width of the tongues and grooves is continually varying.

This knife was adopted and used with perfect success by Mr. E. Soule, corner 6th and Berry streets, San Francisco, in making the flooring for the Palace hotel in this city, after much difficulty with the knife in ordinary use from heating, the flooring being very hard oak.

The Randolph knife will run through the hardest knot, and will take off one and one-half inches from the edge of flooring with the greatest ease, and without splitting or fracturing the edge, even of cross-grained lumber, and without choking the machine.

The inventor, S. P. Randolph, can be found at present at the office of S. N. Putnam, No. 704 Montgomery street, San Francisco, where any further information can be obtained.



RANDOLPH'S PATENT LIP SAW TEETH AND MATCHING KNIVES.

Instead of using machinery in the vintiug of wine many of the Los Angeles mannfacturare employ (so the papers say) clean limbed, strong muscled Indians to tramp out the purple fluid from the luscious fruit.

A special telegram from Berlin says that the Turkish government has declared its willingness to give the great powers any guarantees, compatible with the nation's dignity, for the fulfilment of her financial programme.

The Monterey whaling companies have, during the last season, been the recipients of many large and oily favors, having captured upwards of 100 whales, and obtained over 2,000 barrels of oil.

General business in New York city is reported as being very much depressed.

Saving Gold from Sulphurets.

Messrs. Editors:—The remarks of Mr. Melville Attwood, republished in your last issue, are interesting, but his conclusions do not seem to accord with facts within my knowledge.

As I presume Mr. Attwood is not like the French philosopher, who, in a similar case, said, with a shrug, "so much the worse for the fact; I cannot 'elp eet;" I will state those facts, in the hope that he may be induced to throw some further light on a subject of great importance.

Some years ago, having to assist in working some very rich auriferous pyrites, I took a small sample of the matter, and, by pulverizing in an agate mortar, and very careful washing, tried to find out in what condition the gold existed. I was enabled to recognize the particles of gold, which were comparatively coarse, by their ductility under the pestle; but, though they were distinctly flattened, I utterly failed, by grinding, to develop the gold color, as they persistently retained the precise hue of the sulphurets till roasted, or treated with nitric acid, when the gold was distinctly visible to the unaided eye, nor could I induce it to unite with quicksilver until so treated.

On other occasions I have examined pyrites which, however finely pulverized, failed to show gold with the aid of a good lens, yet on being burned, or treated with acid, it was abundantly visible without the lens.

As to the Cometock ore, Mr. Attwood thinks that only two per cent. of the contained silver is in a mineralized state, by which I understand that all the rest is metallic. I am not prepared to dispute this, though, with all respect, I take the liberty to doubt it; but it is well known that the parties engaged in working those ores have been in the habit of guaranteeing only 65 per cent. of the assay, and the best results I have ever heard claimed for the common pan process did not exceed 75 per cent. of the value, a considerable portion of which was gold, which probably exists entirely in the metallic state in these ores; while I have been repeatedly assured, by those who ought to know, that not more than 50 per cent. of the silver is extracted on an average.

Now this ore is all ground fine, and according to Mr. Attwood's views it would seem that a better result should have been attained; for though he considers it an error to grind in the pans, instead of crushing finer in the batteries, I presume he does not attribute the failure to amalgamate to that circumstance. Neither can this failure be ascribed to the use of chemicals, for it is well known that chemicals in pans have been discarded altogether by some operators; not, however, because of any positive detrimental effect, but because of the doubt as to a beneficial effect; and the question is, I believe, still an open one as regards the use of bluestone and salt in pans of rapid motion, the simple fact being, as I have repeatedly pointed out in these columns, that the full effect of these substances cannot possibly be got under such conditions, for the reason that, if added at the time of charging the pans, the ore is in too coarse a state to be rapidly acted on by the chloride of copper; whilst if the ore is ground in the pan, either before or after the addition of these, or any useful agents, the finely divided iron which is separated by abrasion from the shoes and dies, and distributed through the pulp, soon decomposes the salts of copper, or combines with acid, and results simply in chloride of iron, which is of little, if any use. Any benefit which is obtained from the use of bluestone under such conditions must be due rather to the action of reduced copper, than to the action of copper chlorides on the ore.

Granting then, that the chemicals, as used in the pan process, amount to but little either way, the fact remains, that fine grinding and amalgamation fail to give satisfactory results. Does Mr Attwood suppose that it would make a material difference if the ore, instead of being rather coarsely crushed and then ground fine in the pans, were to be finely crushed and amalgamated without grinding (and without chemicals) in barrels? Even if the case were as Mr. Attwood supposes, it would still be very doubtful if any advantage could be thus gained, as it can be shown that results which leave little or nothing to be desired can be got by the use of chemicals, *properly applied*, without such very fine crushing as would be necessary without chemicals, and at less cost. In the Patchen process, the chemicals are applied to the ore as it comes from the battery, crushed, perhaps, a little finer than is usual, but not extremely fine, in a wooden or copper vessel, before the amalgamation in pans, and the results are stated to be over 90 per cent.

In 1868 I treated, in a small way, Comstock ores just as they came from the stamps, by amalgamation, with the aid of chemicals of the value of 50 cents to the ton, exclusive of salt, and obtained 90 per cent. of the silver and 80 per cent. of the gold, the value ranging from $22 per ton up to hundreds. If the chemicals are used directly in the pans, it is much better to use the dichloride of copper than bluestone and salt, as is fully shown by Dr. Linzweert,

---

Men and teams are busy at work on the line of the proposed railway from Dumbarton Point to Alviso. About half the distance (six miles) has been graded over high ground. The remaining portion is across marsh land and will require ditching and dyking, and be performed mostly by Chinamen. About two miles of this work has to be done between Newark and the landing on the Bay, and about four miles just this side of Alviso.

The Santa Rosa *Democrat* says that the north part of that town is rapidly improving; building after building is going up, and others are in contemplation as soon as College avenue is opened. Wilson's Addition is now offered for sale in lots, and altogether real estate is in demand, and the prospects healthy for an advance in values the coming season.

The Hollister *Enterprise* reports that R. M. Shackelford is driving along the water contract for the works in that village, as fast as possible. Hands are at work excavating the foundation for the reservoir on the top of the hill. The well pipe and most of the other machinery are on the ground.

The Concentrating Works at Falun, Sweden.—Continued.

[Written for the Press by Chas. C. Rukeyer.]

The Pulverization of the Stamp Stuff and of the Jigging Wastes.

For the pulverization of that part of the pick stuff which contains the copper pyrites in fine seams, or finely disseminated, and for the further liberation of the valuable minerals in the jigging wastes, eight stamp batteries of four stamps each are used for the present.

The stamp stuff from the sorting tables is raised on the hoists, and the jigging products by means of the cup elevators, from the dressing floor into the garret, and are there transported by rail into the hoppers behind the stamps; these contain for each battery one compartment of 150 cubic feet capacity. From these hoppers the ore is fed mechanically into the mortars of the batteries.

The discharge from the stamps takes place with so-called backed water; part of the brass wire screens have holes of 1.5 millimeter, and part of 0.7 millimeter.

The whole pulp of batteries *d* 1 is collected into one sluice, which carries it over four small funnel boxes. Down to the discharge holes of these funnels run half-inch iron pipes, contracted at the lower mouth, which carry in water under high head, whereby the funnels are kept open; the fine sands and slimes are also thereby separated from the coarse sands discharged from the lower orifice of the funnels. This funnel discharge, consisting of fine grit and coarse sand, is raised by the cup elevators *d* 2 and *d* 3 into the classing drums *d* 4 and *d* 5, and the overflow of the funnels likewise by the elevators *d* 6 and *d* 7 into the V boxes for grading.

These classing drums, *d* 4 and *d* 5, are seven feet long, and conical, as those before described, but they are provided with two concentric mantlets of punched sheet copper. The largest diameter of the inner mantle is 4' 4", the smalles 3 ft. 6 in., and the perforations 1 mm., while the holes in the outer mantle are 0.7 mm. The distance between the mantles three and one-half inches.

The four inch steel shaft of the drum lies horizontal. The mean peripheral speed of the drum is 2.2, so that ten revolutions per minute result.

These drums produce three classes *jigstuff*, the reserve of the inner mantle, consisting of 1.5 mm. grit; the reserve of the outer mantle, of one mm. sand; and the screenings of the latter. of 0.7 mm. sand. Grit and sand run directly into six Harz. sand jiggers, *d* 8.

Each stamp pulverizes seventy to eighty pounds stamp stuff per hour, when 1.5 mm. screens are used; with screens of 0.7 mm. openings, the work of each stamp is only fifty-five to sixty-five pounds.

The consumption of battery water is per stamp and minute about 0 4 cubic feet, when the 1.5 mm. sieves are used, and 0.3 with the finer.

The thirty-two stamps and the six jiggers require the attendance of one man only, who executes besides the smaller repairs on the batteries.

The frames of the batteries are of cast iron, and rest on cast iron bed plates, being bolted to them, and down to the foundation. The stems of the stamps are of two and three-fourth inch steel, square section, and are eight feet long. They are driven directly into the cast iron shoes. These latter have a recess five and one-half inches deep in their upper end, lined with wooden wedges, between which the taper end of the stem is driven. The face of the shoes is square, because filling up the space in the mortar more than the round form. The wooden guides of each stem can be set up independently of the others in a very simple and convenient manner, which is certainly a good point.

The weight of the fully armed stamp is 380 pounds, Swedish. They make fifty-seven to sixty drops of eight to ten inches per minute.

The cast iron cams are triple, and are faced with exchangeable one-half inch steel plates.

A further detailed description of the stamp batteries is omitted, as being not of sufficient interest here. Although of good and simple construction, having many excellent points in the details, especially as compared with other European stamp batteries, still they are not,

DEWEY & CO.

American & Foreign Patent Agents.

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissnes taken ont; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken np and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Bnsiness promptly and thoroughly conducted.

Our intimate knowledge of the varions inventions of this coast, and long practice in patent business, enable ns to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valnable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introdnction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, inclnding Great Britain, France, Belginm, Prnssia, Anstria, Victoria, Pern, Rnssia, Spain, British India, Saxony, British Colnmbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cnba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chili, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, hut the drawings and specifications shonld be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Onr schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some iostances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the conntry SOONER than any other agents.

The principal portion of the patent bnsiness of this coast has been done, and is still being done, throngh our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of goverment, delays are even more dangerons to the inventors of the Pacific Coast than to applic ants in the Eastern States. Valnable patents may he lost by extra time consnmed in trans mitiing specifications from Eastern agencies back to this coast for the signatnre of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and bnsiness transactions will be held strictly confidential hy ns. Circnlars free.

Home Counsel.

Onr long experience in obtaining patents for Inventors on this Coast has familiarized ns with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application hy pointing them to the same thing already covered hy a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right bnsiness, believing that the mutnal conference of legitimate bnsiness and professional men is mntnal gain. Parties in donbt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advise of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money hut their inventions also, from this cause and consequent delay. We hold onrselves responsible for all fees entrnsted to onr agency

Engravings.

We have superior artists in our own office, and all facilities for prodncing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable nse.

DEWEY & CO.,

Unitod States and Foreign Patent Agents, pnblishers Mining and Scientific Press and the Pacific Rural Press, 224 Sansome St., S. F.

Mining and Scientific Press.

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It bas been conducted by its present proprietors for ten years, during which period it bas been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-eized, handsome sheet, is unequalled hy tbat of any other American weekly west of the Mississippi.

As a PRACTICAL MINING JOURNAL it bas no rival on tbis Continent.

It is tbe only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Miners, Assayers, Millman, and Metallurgist in the United States should take it.

Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columns of fresh and valuable information.

Mining Enginsers, Superintendents, Metsllurgiste, Mine Owners and Mine Workers throughont the world should profit by its illustrations a d descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughout the land, in high or bumble situation, who would avoid literary trash for genuine information, should SURSCRIBE AT ONCE.

DEWEY & CO.,
No. 224 Sansome street, S. F

UNITED STATES

Mineral Land Laws, Revised Statutes,

And Instructions and Forms Under the Same.

We have jnet issued a pamphlet containing tbe general mineral land laws of the United States, with instructions of the Commissioner of the Land Office The contents of thie pamphlet comprise sll of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Ststnto of May 10th, 1872, with Instructions by the Commissioner of tbe Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870 Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of tbe Claim; Proof that Plat and Notice remsined Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publiaher; Proof of Publication; Affidavit of $500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There ie also given tbe U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the bands of every one having any mining intereets. DEWEY & CO.,
Publisbers of MINING AND SCIENTIFIC PRESS, S. F.

Designing and Engraving at This Office.

We are prepared to do fine Wood Engraving for illustrating Landscape Scenery, Buildings, Machnery, Works of Art, Manufactured Articles, Trade Marks, Seals, Etc. We have a first-class

Machine for Engraving

A portion of the work, which can he finished thereby more perfectly than by the eye and hand alone. Our patrons can depend upon first-class work always, and at reasonable prices. Samples can he seen at our office.

DEWEY & CO.

THE MINING AND SCIENTIFIC PRESS, of San Francieco, entered upon its thirty-first semi-annual volume last Saturday. It is most appropriately named, and sustains well its name, containing more really useful information upon mining, scientific and kindred subjecte, than any other paper on the Pacific coast. Dewey & Co., tbe publisbers, are well known as agents for securing patents; in fact, most of the patents for inventions on this side of tbe continent are secured througb them. The PRESS is deservedly prosperous. —[Gold Hill News.

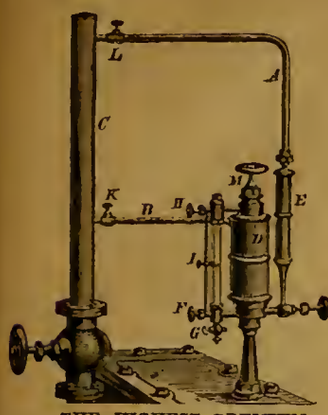
Machinery.

N. Seibert's Eureka Lubricators.



THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stopps; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted t give satisfaction. Patented February 14, 1871. Manufactured by California Brass Works, 125 First street, S F. 24v23

(Continued from Page 265.)

as a whole, likely to be imitsted in this country.

Tbe self-feeders for the bstteries are similar to those used for the feeding ot the rubbisb wash drum and tor the Cornish rollers, as above described. The percussion trough is six feet long and seven inches wide, the inclination 20°. The upper end is hung with rods to the hopper, the lower rests nn a roller. Instead of being pushed hack hy a csm, as above, the tappet of the stamp strikes npon an upright rod, which acting on a simple angle lever, sffects the backward movement ot the feed trough; tbis movement does not exoeed one-tonrih ct an incb. A componnd rnbber buffer propels the trough back into its normal position. On the arm ot the angle lever on whicb the npright rod rests, is an adjnstment, to compensate for tbe wear of tbe shoe and die.

These self-teeders hsve not once failed to serve during the eighteen months in which the stamps have been in use. They are not new, a similar construction having been in use tor quite a long time in Austrian concentrating works. The main difference is in tbe use of the rubber buffer, for the forward propulsion nf the trough, with which, bowever, tbe effect is more pertect, as it permits a regulation of the feed at any moment, hy a simple adjustment of the tension of the buffer.

The Tulloch's teeder here used ie neither as simple nor as perfectly adjuetable as the self-feeder at Falnn; its portable form, however, makes it better adapted to the batteries as here constructed.

Cast steel sboes and dies bave snbsequently been introduced, whereby the interruptions beoame less frequent, and the oost for repairs diminiehed, while at the same tims the effect is materially hightened, hecause tbe faces nf such shoes and dies remain quite regular for a long tims.

VI. The Sieving or Jigging.

For ths eortiug ot the rnbbish, classed with tbe sieve drums, and ot the gravel, grit and coarse sands, produced in the work ot the rock breakers, the rollers and the stamps, twenty-five jigging machines are need. These are set up in a row, as near as possible to the classing drums, so that the jigstuff, as above mentioned, is delivered directly iu part, partly by mecbanioal contrivances, into the sieves of the jiggers.

Fourteen of these jiggere are entirely of iron, as they are made by the mining machiuery wnlks nf the Humboldt company in Deutz, near Cologne. The meohanism for the movement of the pietous in these machines is such as to produce a slow upwsrd, and a rapid downward motion, and consists for the gravel machines of a orank and slide lever movement, whereas in the jiggers tor the finer stuff tbe piston rod is raised by a cam, and is propelled downward by a ruhber bnffer. The tension of the latter and tbe lift of the oam is regulated with ecrews. Each machine is provided with a tight and loose pulley. Tbe boxes of the jiggers are made nf strnng ebeet iron, and the frames into whioh the sieves ars laid, are of oast iron.

All of these jiggers are fitted up to be automatic and work contiuuously, in oontormity with all the other machinery in the works

Besides these iron jiggers, tbere are eleven in operation whose boxes are made of two-inch wooden staves, lined inside with one-inch boards. Four ot these are tor tbe treatment of tbe coarse sande and grit. These also have a slow npward and an accelerated downward motion ot the piston. Tbe mechanism here also consiete ot two shafts, one of them carrying on a short arm in the middle the piston rod; tbe other the pulley shaft. Each shaft carries at one end a lever, and these are connected with each other by a short rod. The action here is the same as in the orank and elide lever motion, but the mechanism ie simpler.

For the adjustment of tho stroke ot the piston, the arm to whicb the latter is attached is also provided with a elide pin.

Seven wooden jiggers and two iron oues are erranged to discharge through an ore bed; that is, the conoentrated stuff passes through a strata of ore, resting on the eievee, into the bottom compartment of the machine. The motion is here given to the pistons by eccentrios, acting directly on to the piston rods.

For the eorting of the classed jigstuffs from the rubbish washing works, the eeven jiggere, *a* 10 to *a* 16, are need. The store boxes, which receive the reserves ot the classing drums, stand so high that the sluices mediating the transportation of the material into the sieves have the requisite fall.

Below tbe floor of the etore boxes runs a wrought iron shaft, carrying for each clase of jigstuff a cell wheel one foot in diametor. On the extreme end ot the shaft is a toothed wheel, which ie put in motion by the engaging of a pawl in connection witb rod and lever, causing tbe contente of the cells to discharge into the transportation eluices, and turther on into tbeir respective sievee. The transportation in the gutters or eluices is effected with the aid of water, and to facilitate it, the gutters have an elliptio torm, and are lined inside with sheet iron; or they bave an elliptic bottom ot caet iron, whicb can be exchanged when worn out.

Three of the jiggers serve for two sorts ot gravel each; while one sort is heing fed into the eieve, the other accumulatee in the etore box. The four machines following, work ouly one sort each, so that tor tbese the corresponding etore boxes and teeding meohanisms come into requisition, only in oase of repairs on one or the othsr of the jiggers.

Each jigger yields two products or sorts, namely, the *jig ore* for the smelting works, with five tn ten per cent. copper, and the skimmings, with one to two per cent. copper, which are subjected to fine polverizstion in the stsmp batteries. These skimmings or jigging wsstes are discharged at each stroke of tbe piston, over the whole width nf the overflow of the sieve box, and run, together with tbe water, into the basin ot elevator *a* 17, and are there lifted into a reservoir in the garret. Out of this reservoir they drop into cars plsced beneath, and are thence transported into the hoppers hehind tbe stsmp batteries.

To rid the skimmings of water as mnch as possible, tbe cnps of tbe elevator are perforated with three mm. holes. The elevator has a slow motion, only about 0.13 feet per secoud, so that tbe cup tskes 3.8 minutes to perform its upward journey. The cups being filled to only about one-eigbth their capscity, permits the draining ot the water the more easily. Moreover, the bottom ot tbe store box into which the cups disoharge, is provided with a grate, between whicb the water can take its passsge back into the elevator basin.

Barren ssnds or deads can rarely be separated in jigging, because the skimmings almost invariably contain finely disseminated copper pyrites.

Since with the arrangement just desoribed, only trifling hand labor is required, the seven jiggers are attended to by one man.

For the sorting of the material produced by the rock breakers, and olaseed in the apparatus *b* 5 and *b* 6, the seven jiggers, *b* 9 to *b* 15, are in use. Their arrangement and operation corresponds witb that above described.

Tbese yield, like those, rioh oree for the smelter, with about six to fourteen per oent. copper, and skimmings or wastes, with 1.5 to 2.5 per cent. copper for fine pulverization under stamps; tor this purpose the latter are lifted by the elevator, *b* 16, into the store box in the garret.

The attendance ot these eeven jiggers also requiree the services of but one man.

The sorting of the material resulting trom tbe classification of the product from the Cornish rollers, is pertormed by tbe five jiggers following, c 9 to c 13, the arrangement for feeding and discharge being the same as just above described.

Each of tbe first tbree of these machines serves for working two sizes, the two following for one size only. They yield, as the others, two products or sorts, namely: jig ore, with six to fourteen per cent. copper, tor the smelter, and tbe skimmiugs, with 1.5 to 2.5 per oent oopper tor fine pulverizstion. These letter are raised by the elevator *a* 14 into tbe garret, and there dnmped into railroad care.

The fiftb of these jiggers, c 13, serves for the sorting of the screenings of the seventh olaseing drum, consieting ot 0.7 mm. sand, whicb is separated from the reet of the pulp by a smell funnel, and flowe directly into the jigger. It yielde "small ore" tor the smelter, with five to nine per cent. copper, and "good waste," witb one to 1.5 per cent. oopper, which is litted, together with the pu'p from the stamp batteriee into the boxes tor grading, and thence given to their respective machines for further separation.

The above five machines ars also attended by one man ouly.

The eortiug ot the material separated from the battery pulp, in the manner above described and olassed in the sieve drums *d* 4 and *d* 5, ie done in the following six Harz. ssnd jiggers, *d* 8 to *d* 13, whose construction hae heen intimated above, and whiob vary from the usual construction ouly in tbat they hsve only one sieve each.

The classed etuff consists, as already mentioned, ot 1.5 mm. grit, aud one mm. and 0.7 mm. eend.

E ch class has its own maohine, or, there are three of these for each classing drum, the arrangement being suob, tbat the corresponding class trom eaoh drum can be carried into one eieve. The discbarge of the funnels at the batteries can likewiee be given to either of the two elevatore, *d* 2 or *d* 3, in case one ot these, or one of tbe drums, bas to be repaired, etc.

The jigstuff is delivered from the drums directly into the sieves. The machines yield "small ore," with five to nine per cent. copper, which passes through tbe ore bed on the sieve, and ie diecbarged contlnnously out of a one-fourth inch hole in the bottom of the machine; and overflow sands, with 0.8 to 1.5 per cent. copper. The overflow ot one to 1.5 mm. eize, is raised by the elevator *d* 14, haok into the stamp battery tor further disintegration, while tbe finer, consisting of 0.7 mm. sand, runs into tbe elevator basin, *d* 6 or *d* 7, to be raised with the rest of the pulp into the V boxes for grading and further separation.

These eix machinee are attended to by the workman iu charge of the batteriee.

[To be Continued.]

Appreciation Abroad.—We copy the following from the *Mining and Monetary Gazette*, of London, Eng.: "We deemed it advisable, as affording valuable information to our readers, to publish in recent issues of *The Gazette*, the full text of the "United States Mining Laws and Instructions, by the Commissioner of General Laud Office," taken from our talented contemporary, The Mining and Scientific Press, of San Francisco. The documents have now heeu issued in a handsomely-hound volume by Messrs. Dewey & Co., the publishers of onr transatlantic contemporary, and it will he found very nseful to those already interested in American mines, and to others who may be tempted to embark in that enterprise in the States."

Woodward's Gardens embraces an Aquarum, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday eveuing last, Dr. Henry Gibbons, Sr., in the chair.

Dr. G. F. Becker read a paper entitled "Notes on a new Feature of the Comstock Lode," which we give in another column.

Dr. Hermann Behr read a short paper on

The Phylloxera.

He said, among other things, that tbis terrible vine-destroying insect very much resembles tbe common mosquito in its general appearance. It first attracted the attention of scientists in England in 1863, making its appearance among the vines grown in hot-honses. The history ot this destructive insect is somewhat hypothetical. In the language nt science the phylloxers is one of the "aphidians," and is propagated exclusively by parthogenesis, that is, the insects all belong to one sex. Each temale, after depositing her eggs, dies. The number of eggs deposited diminisb with each generation. According to the best anthorities, each individual insect lays npon an average no more than four eggs. From these eggs develops a new form ot phylloxera, the winged female, whioh swarms and deposits a brood of wingless males and females, the malee coming from small eggs, the females from larger ones. These small ineecte, destitute of organs capable of inflicting direot injury to vegetation, are nevertheless exceedingly dengerous, for they are the indirect agente of wide-spread devastation. If it were not for the winged variety, tbe phylloxera, with its imperfect organe ot locomotion, would speedily die out with the vines which turnisb it with food and shelter. From the utilitarian point of view of the vine-grower, the one important thing to be done is to destroy the winged variety—the "flyers"—whicb are the moet dangerous and at the same time the most accessible to offensive warfare. The wingless form is partially protected by its subterranean mode of lite, and by a powertul vitality that resists the effecte ot all ordinary poieone. But to approach the practical and ntilitarian side of the eubject, whioh most nearly concerns the grape-growers of tbe State. Like the moth and the mosquito, the phylloxera is tond of light. It ie attracted irresietibly by the glare of conflagration. Dr. Behr infere from tbie dietinctive tendency of the insect that the best praoticel mode ot guarding against its ravagee is to kindle bonfiree in the vineysrde ravished by them, thus luring them to immolation by fire.

Snail Shells.

Mr. R. E. C. Stearne read a paper on the "Vitelity of Land Shells." He sbowed a living specimen of a snail shell, one of many collected by Profeesor Davidson in 1873. After a sleep of over two years, the presenoe of ohickweed and other succulent vegetablee revived the torpid creatures, and they awoke from tbeir lethargic repose. One in the Britieh Musenm lived four years; and another case of a six-year term of lite is reported. It will be noticed that these animals come from rainless regione, where the tood supply of land molluske is precarious. Doubtleee by a procese ot evolution they were adapted to their habitat. Long hibernation gives them vitelity, and we bave another illustration of the compeneate work of nature. Mr. Stearns aleo submitted for publication desoriptione of two new shells. We will give Mr. Stearne' paper in tull in our next issue.

Mr. Henry Edwards submitted for publication, No 15 of his series of papers on "Pacific Coast Lepidoptera," being a description ot a new species of *catocula*, from San Diego.

Mr. J. F. Jerome presented specimens of candle nut. Mr. C. D. Gibbes described thie as *Aleurites triloba*, a tree of the family *Euphorbaceæ*, which growe to the hight of twenty or tbirty teet. The trnit is about two inches in diameter, the inner nut a very hard shell, within which the meat is preserved for yeere. It ie good to eat, but rather rich. The nil is easily expressed and is imported into England for candle-making. As a drying oil it ranke among the best. This is called by the natives of the Sandwich island the "Kukui tree." The Hawaiians string the kernele of the nuts on slender strips of bamboo and ligbt them as candlee. They burn well, with a peculiar but pleasant odor.

Our Agents.

Our Friends can do mnch in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. Tharp—San Francisco.
B. W. Crowell—California.
A. O. Champion—Tulare, Fresno and Inyo Counties.

SCIENTIFIC PRESS

Patent Agency.

SCIENTIFIC PRESS—Mining and Mechanical.

PACIFIC RURAL PRESS—Agricultural.

Publishers, Patent Agents and Engravers,

No. 224 Sansome Street San Francisco Cal

The Mining and Scientific Press.

[Established in San Francisco, 1860.]

Is the leading mining journal in America, and enjoys a large circulation among the more intelligent operators and workers in the gold fields of the world.

As a scientific and mechanical representative of the Pacific Coast, it is decidedly popular and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivalled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer will find profit by its reading.

Subscription, $4 a year, in advance. Sample copies post paid, 10 cents. As an

ADVERTISING

Medium for the Pacific Coast, it is superior to any other journal for all kinds of mining and hydraulic machinery and other mechanical work, building materials new manufactures and inventions. Our rates are very reasonable compared with those of other first-class journals. DEWEY & CO., Publishers.

224 Sansome street, San Francisco.

SECOND EDITION—REVISED AND ENLARGED.

The Explorers', Miners' and Metallurgists' Companion.

Containing a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy.

Containing 672 Pages and 83 Engravings

BY J. S. PHILLIPS, M. E.,

Of California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE, bound in cloth, $10.50; in leather, $12. Forwarded by mail for 50c. extra, at the Mining and Scientific Press Office, by

DEWEY & CO.

Every Mechanic

Should have a copy of Brown's

507 MECHANICAL MOVEMENTS,

Illustrated and described.

Inventors, model makers and amateure mechanics and students, will find the work valuable far beyond its cost. Published by Dewey & Co., Patent Agents and publishers of the Mining and Scientific Press.

Price, post paid, $1.

A Good Binder for $1.50.

Subscribers or this journal can obtain our Patent Elastic Newspaper File Holder and Binder for $1.50—containing gilt title of the paper on the cover. It preserves the papers completely and in such shape that they may be quickly fastened and retained in book form at the end of the volume, and the binder (which is very durable) used continuously for subsequent volumes. Post paid, 25 cts. extra. It can be used for Harper's Weekly and other papers of similar size. If not entirely pleased, purchasers may return them within 30 days. Just the thing for libraries and reading rooms, and all who wish to file the Press. 1amhp

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY CO., Mining and Scientific Press Office, S. F.

BY QUIDO KUSTEL,

Mining Engineer and Metallurgist.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price $2.50 coin, or $3 currency, postage free

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO $5.

Nevada and California Processes of Silver and Gold Extraction, for general use, and especially for the Mining Public of California and Nevada, with full explanations and directions for all metallurgical operations connected with silver and gold from a preliminary examination of the ore to the final casting of the ingot. Also, a description of the general metallurgy of silver ores. 1864.

As its title indicates, this work gives a wide range of information, applicable to all vein miners and workers in precious metals, affording hints and assistance of exceeding value to both the moderately informed and the most expert operator.

Price, $5 in cloth; $5 in leather—colu.

BY OTHER AUTHORS.

The Quartz Operator's Hand-Book; by P. M. Randall. 1871. Revised and Enlarged Edition. Cloth bound, 175 pages. Price, $2.

Sulphurets: What They Are, How Concentrated, How Assayed, and How Worked: with a Chapter on the Blow-Pipe Assay of Minerals. By Wm. M. Barstow, M.D.; 1867; cloth bound, 114 pages. Printed and sold by Dewey & Co. Price, $1; postage free. The best written work, and most complete work on the subject treated.

ANY OTHER BOOKS DESIRED will be furnished at the most reasonable rates by Dewey & Co., Mining and Scientific Press Office, S. F.

Pacific Rural Press,

A first-class 16-page Agricultural Home Journal, filled with fresh, valuable and interesting reading. Every farmer and ruralist should take it. It is immensely popular. Subscription, $4 a year.

DEWEY & CO., Publishers,

No. 224 Sansome street, SAN FRANCISCO.

Thursday Noon our last forms go to press. Communications should be received a week in advance and advertisements as early in the week as possible.

Just Published.

Thoughtlessness.—Persons sometimes return their paper, marked "stop this paper." Their name being pasted on the sheet they think that is all we need to be able to cross their names off. Now that is thoughtlessness. Your P. O. address is needed as much as your name. We have thousands of names arranged only according to locality. Our mailing clerk does not know where everybody lives.

Mining and Other Companies.

Cloverdale Mining Company — Location of principal place of business, San Francisco, California. Location of works, Cinnabar District, Sonoma County, California.

Notice is hereby given, that at a special meeting of the Stockholders, held on the fifteenth day of October, 1875, an assessment, (No. 3) of two hundred dollars per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, No. 305 Clay street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of November, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 15th day of December, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale. ED. B PARTRIDGE, Secretary.

Office, No. 305 Clay street, San Francisco, California.

Keystone Quartz Mining Company—Principal place of business, San Francisco, California. Location of works, Butte Township, Sierra county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 22d day of September, 1875 an assessment (No. 5) of fifty (50) cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at the office of the company, northwest corner Pine and Sansome streets, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 8th day of November, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 29th day of November, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

LOUIS VESARIA, Secretary.

Office, northwest corner Pine and Sansome streets, San Francisco, California.

Hope Quicksilver Mining Company—Location of principal place of business, San Francisco, California. Location of works, Cinnabar Mining District, Sonoma County, State of California.

Notice is hereby given, that at a regular meeting of the Board of Directors, held on the 2d day of August, 1875, an assessment (No. 2) of Five cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company Room 2, No. 403 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 8th day of September, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 30th day of September, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JACOB HARDY, Secretary.

Office, Room 2, No. 403 California street, San Francisco California.

POSTPONEMENT.—The date of the delinquency of the above assessment is postponed to the 8th day of October, and the date of delinquent sales to November 1st, 1875. By order of the Trustees. J. HARDY, Secretary.

September 8, 1875.

SECOND POSTPONEMENT.—The date of the delinquency of the above assessment is postponed to November 9, 1875, and the day of delinquent sales to December 1, 1875. By order of the Board of Trustees.

JACOB HARDY, Secretary.

San Francisco, October 8, 1875.

Mount Auburn Gold Quartz Mining Company. Location of principal place of business, San Francisco, Cal.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills:

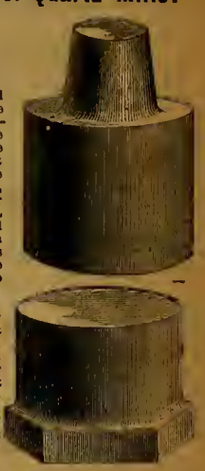
[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.



Address all orders, with dimensions, to W. R. Townsend, Secretary.

54 BUSHELS OF CORN AN HOUR.
HARRISON'S
LIGHT, VERTICAL BURR MILLS
BAKER & BACON, MILLERS AND LUMBER DEALERS, SOUTH VERNON, VT., write July 15th:
"We have been running two of your LIGHT VERTICAL CORN MILLS for the past 6 months with remarkable results, and have ground over 80,000 bushels of corn into No. 1 meal in that time, running the grist-mill nights only, as we run our saw-mill in the day time. We have often ground in the 20-inch Mill (which weighs about 500 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 24,300 lbs., or 434 bushels. To do this we have to run at a speed of 1,200 turns per minute, and use about a 20-horse power. You may refer parties to us for further information, and when we have tested your HEAVY VERTICAL MILL, we shall take great pleasure in giving the results."

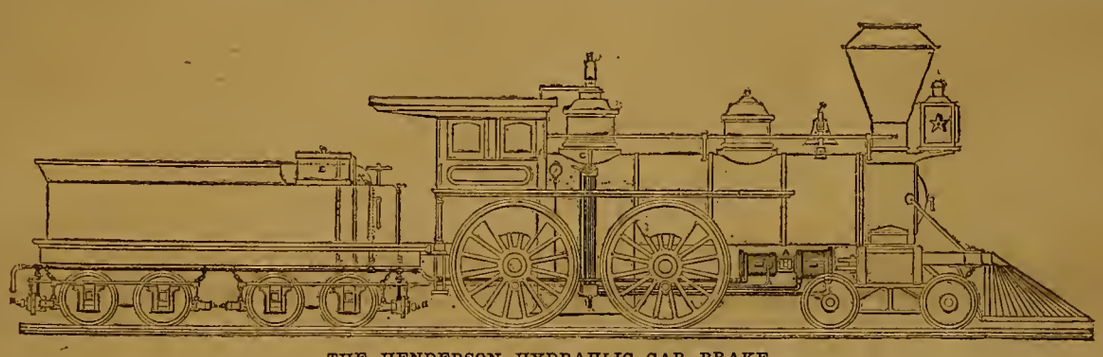
VOLUME XXXI Number 18.

The Henderson Hydraulic Car Brake.

As the subject of powor brakes has lately heeu prominently brought forward in the pnblic journals we have thonght it proper to draw nttention to a new brake which is made by the Honderson hydranlic car brake company, 119 South Fourth stroot, Philadelphia, Pa. We give an illustration herewith, from which the principle of its operation can he seen.

This brake is so simple in its construction and operation that it is almost impossible to give any detailed description of it further than to state that the power is derived by a very small portion of the steam from the boiler used in a pressnre engine, consisting of a small hydranlic press operated by a donble acting steam cylinder, the valve of which is workod, by the haud of the engineer. There is a piston in each cylinder; steam actuates the one, forcing the fluid from the other, creating hydranlic pressure within pressnre boxes, one of which is attached to one break beem on each trnok. An air cushion is provided above the press piston to prevent striking the head when coming back light.



THE HENDERSON HYDRAULIC CAR BRAKE.

The press receives water from a tank, which may he the engine tank or a special tank provided for the purpose, through a pipe furnished with a check valve opening towards the press cylinder, in snch a manner that the fluid cannot return to the tank. The supply is arranged to feed autometically; any supply or leakago past the press piston is at once returned to the supply tank in a small return pipe. For low temperetnres' a mixture of equal parts of glycerine and water is used in lieu of water, which is safe to 24° Farenheit below zero. The pressure boxes are of cast iron, simply bolted together as they come from the foundry, embracing a dish-shaped flexible disphregm of vulcanized india rubber. The body casting is of a similar form bnt somewhat deeper; a ram is fitted to the hollow of the diephragm, its reduced diameter passing throngh a projecting guide, furnished with a hydraulic packing. Two iron rods connect the end of the ram to the opposite break beam.

When pressure is applied, the body casting presses in one direction, and puts its breke on, and the rams going outwards draw the opposite brekes on—the movements of the rems being from one half an inch to one inch. When the pressure is relieved by the retraction of the press piston, the atmosphere reacts on the area of the rams and forces them back, assisted by the tendency of the diaphragms themselves to recover their normal condition. Double iron pipes are used nnder the tender and cars. A branch, governed by a 3-way cork conuects again with a tank above, by which the engineer can blow around the whole double line of pipes, to clear them of air before starting.

Flexible hose between the cers is nsed, furnished with hydraulic couplings, which, it is obvious, must he light, both with and without internal pressure, and to couple and uncouple without waste; peculiarities possessed by this coupling alone, which also has a cork joint and safety disconnecting chain attachment, preventing the coupling from blowing apart. These, with the steam valve and a few fittings, comprise all the machinery of the brake.

In the drawing, the pressure engine is shown under the forward part of the shell of the boiler; if preferred, it may be placed vertically on the side of the fire box, or under the tender. In the engraving, *A*, is the pressure engine; *B*, the pressure box; *C*, the breke valve, and *E*, the fluid tank.

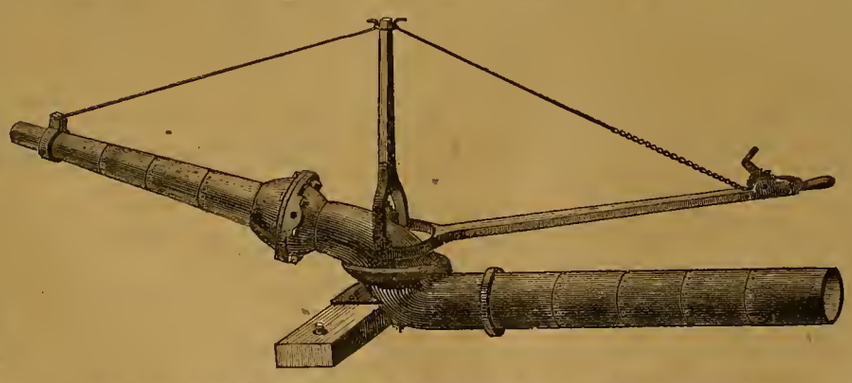
The points of merit claimed for the brake are as follows: 1st. Doing away with the use of complicated pumping machinery. 2d. Dispensing with the use of cylinders under the cers, and with their necessary pistons, piston packing, stnffing boxes, recoil springs, levers and joints, chains and rods for operating the brakes, and all the lost motion produced thereby. 3d. Doing away with all lubrication of brake cylinders, there being no parts that require oiling, and no parts that can he affected by dust. 4th. Ready for instant action, when steam is up, without special preparation, as pumping up for pressure, the boiler being the reservoir of power. 5th. The brakes are applied by the boiler pressure, are released by atmospheric pressure, and in no way interfere with the working of the hand brakes. 6th. The brakes are applied simultaneously from both ends of the train, reducing the time of application, and there is no jarring or jolting. 7th. Its simplicity—no delicate or complicated machinery is nsed in its construction; being chiefly unfinished casting—the cost of maintenance is trifling. 8th. Its economy—steam being only used at the moment of applying the brakes, and directly to that purpose. 9th. Its cheapness.

In addition to these advantages it has been discovered by actual experiment that, owing to the peculier arrangement of the double system of pipes used, either line can be cut loose anywhere between any of the cars without effecting the operation of the brake as a whole, or interfering with the action of a single brake-shoe. On the other hand, any individual truck can be shut off, or the whole may be shut off, with any selected exception. The use of the double system of pipes also causes the brakes to he applied from the rear end of the train, simultaneously with those at the front end, gaining in time in the promptness with which all the brakes are applied, an important advantage, when a single instant of time may avert disaster.

Improved Hydraulic Nozzle.

The accompanying engraving represents the well known Little Giant hydraulic mining nozzle with a new lever and crank attachment, as manufactured by R. Hoskin, of Dutch Flat. All hydraulic miners will recognize at a glance the utility of this arrangement, without any detailed description being necessary. The improvement reduces the power required to move the pipe horizontally, fully fifty per cent.

When piping at ordinary elevations the pipeman may stand either at the lever or the nozzle; when piping at extremes of elevation or depression, he uses the lever, and is enabled to keep it in a position in which he can apply his power to the greatest advantage. A simpler arrangement could scarcely be devised, or one which would be more practical and useful. It often occurred in the old arrangement that when the pipe was elevated and it had to be turned, the pipe-men was compelled to bring it to a horizontal position, turn it, and then elevate it again, sometimes washing into ground he did not want to wash into, simply because he could not turn the nozzle when in its elevated position.



LITTLE GIANT NOZZLE, WITH IMPROVED LEVER AND CRANK ATTACHMENT.

By means of the apparatus devised by Mr. Hoskins this difficulty is done away with, and the Little Giant made much easier to handle. By turning the crank he brings the nozzle at the proper elevation, and the lever in such a position as to be easily handled. By bringing the lever low down he can exert the full force of his strength upon it in the right direction, which could not be done were the lever as high as the pipe-men's head or shoulders. Although simple, this device is an important one to the hydraulic miner, and greatly adds to the usefulness of the Little Giant nozzle. Full particulars will be furnished on application to the manufacturer.

The Wholesale Clothing Trade.

During the coming seasons of the year, when new styles and description of goods constitute the wear or mode, in anticipation of a sound, reliable trade in clothing, the manufacturers of our larger cities, in some instances, are continuing operations on an increased scale, both in making up and in the shipment of the goods to the dealers. Recent improvements in the material and form of clothing, well as the manner in which the work of this nature can be turned out, have chiefly effected the good results which have been attained. The wholesale clothing trade of some of the business houses of San Francisco is of a progressive nature, the continuous extension of the boundaries of sale, the perfection of cut, and the remarkably low figure at which the goods can be disposed of to the trade, making it an indispensable interest for the comfort, convenience and benefit of the people in all classes of society.

Prominent among the leading wholesale clothing houses of this city, is the firm of Messrs. J. Baum & Co., importers and manufacturers of custom made men's youths' and boys' clothing, furnishing goods, etc. The house was established as early as 1854 by Mr. J. Baum, the present senior member, and conducted with the express purpose of supplying to the trade a superior class of clothing. The establishment where the goods are manufactured is located in New York, the business house in this city being devoted exclusively to sales departments and shipments of goods to the different sections of the State of California and contiguous country.

Messrs. J. Baum & Co. lately removed to new quarters, Nos. 521 and 523 Market street, this city, a three-story, iron front building, having a frontage of 52 feet by 155 feet deep. The business departments are so arranged as to enable the business to be conducted on the most expeditious plans, and an elevator facilitates the reception and shipment of the goods. The first floor is devoted to men's and boys' clothing, the second to fine clothing; furnishing goods contained in stock on the third and upper floor.

The several extensive floors are supported by iron columns which range in a row in the middle of the building. The ceilings are made of planed boards, and being painted white, the color of the walls, the general appearance of the place is enhanced, and the difficulty of selection of goods on the part of purchasers obviated by a general diffusion of light which prevails throughout the building. The establishment in question has a reputation of many years' standing, during which time the members, individually, J. Baum, H. Shrier and M. Shrier, have become extensively known.

The Board of Regents of the State University had a meeting on the 21st instant, and adopted a resolution authorizing the president of the university to arrange with the Mechanics' Institute for a course of lectures to be held in San Francisco during the coming winter, and in the same manner as heretofore.

The Donnelly air shaft on the Belcher, finished to 1300-foot level, is not only a work of vast benefit to the mine, but also reflects great credit on Mr. Henry Donnelly, foreman of the mine, the originator and superintendent of its construction.

Father Neri's Scientific Lectures.—The re-opening of Father Neri's popular science lectures at St. Ignatius' college, in this city, will commence on November 4th. The concluding lectures will take place on the evening of November 18th and December 9th. The lectures to be delivered are the three remaining of the unfinished course of six, and for them the best and most brilliant experiments have been reserved. We are assured that tickets bought at the beginning of the course will be good for admission as well as the new ones. The title of the lectures is "Electricity and its Practical Applications."

Two locomotives for the narrow gauge railroad at Saucelito have arrived from the Baldwin works at Philadelphia.

CORRESPONDENCE.

What Constitutes a "Mineral Vein" Within the Meaning of the Law?

MESSRS. EDITORS:—On no subject affecting the industrial pursuits of the country has Congress been called upon for action, that is of more vital importance to the nation than that of mining. None that, from a consideration of the amount of capital invested, or likely to be invested therein, and a successful or unsuccessful issue of enterprise, demanded a more careful digestion of all laws relating to its pursuit. That Congress has vastly underrated the magnitude of the subject must be evident to all intelligent miners who have given the laws of Congress of 1872 relating thereto even a passing examination. Among its many imperfections, although perhaps not the greatest, and calculated to render confusion worse confounded, is the provision, "That no lode claim can be recorded until after the discovery of a lode or vein within the limits of the ground claimed." Now, the *res gestae* of that requirement is, what constitutes a vein or lode within the meaning of the law? and upon this question litigation will arise involving interests of great consequence to the parties litigant. It is possible that the Legislature intended to impose upon the district recorders the duty of examination or of requiring proof of the fact; this they do not, but are satisfied by pocketing their fee. An ardent prospector who finds a showing of auriferous pyrites of iron in a quartz vein, or a trap or granite dyke or other auriferous rock, will fly to the recorder and place it upon record. He has then tied up an area of two hundred yards wide by five hundred in length. If he can find a particle of gold, or ore of any kind, he claims the right of record. He may abandon it as hastily as he seized it, as thousands have done, but should some more enterprising individual make a really valuable discovery within his limits, he is prompt in asserting his rights (?) under the law. Some go so far as to maintain that all quartz veins are metalliferous, and would so testify in adjudications! A satisfactory decision of what constitutes a mineral vein would be more difficult of attainment in cases of veins carrying smelting ores. Here we have more commonly than in other lodes a cleavage or flucan, and an earthy or brecciated matter with clay accompanying it. These, many will maintain, are sufficient evidences of a mineral vein, as indeed many excellent mines are entirely barren of ore in places, only showing these indications of a mine. Yet it is undeniable that such indications have been followed at great cost without finding what can properly be called, in justice to others, a mineral vein. Again, the reader, if a practical miner, will call to mind many instances of "gash" veins, wherein for a few feet ore may be found perhaps in paying quantities, but entirely gives out on a little exploration. Under the law it requires but slight evidence to entitle a man to record, and he may thus tie up an unlimited amount of ground, barring others and inflicting serious injury upon the country. Every one may be fully assured that such locators, and their name is legion, are acting the "dog in the manger;" yet there is no remedy, and although they have done the merest modicum of labor to answer the requirements of the law, they can dictate their own terms to those who would make valuable developments on their domain. It will be asked, *cui bono*, in complaining when the law is established and rights have accrued under it. The answer is, it is hoped that it may induce more careful legislation in the future. The greatest absurdity of the law, and to which the foregoing remarks particularly point, is the conferring so great a width of superficies on the locator, when in reality the location is made or should be made, for the purpose of securing only one lode; then lode or no lode could not affect them. Such ownership carries with it all necessary privileges of surface ground for the convenient working of the mine. This erroneous provision of a very incongruous law is doing great harm, and it is, I believe, the general opinion that Congress has performed in reference to mining legislation a great amount of inexcusable botch-work.

WILLIAM TEAL.

Bingham, Utah, Oct. 6th, 1875.

SHALL WE EVER TRAVEL FASTER?—Speaking of the late celebration in England of the fiftieth anniversary of the inauguration of railways, a St. Louis paper gathers some interesting statistics. The Stockton and Darlington railway, built by George Stephenson and Edward Pease, the first steam railway in the world, was opened September 27th, 1825. In 1830 the first American railway was built, in Massachusetts. In 1873, England had 16,082 miles of railway, and $294,160,140 invested in railway property, and the United States, 70,651 miles of track, and $3,784,543,034 invested. But Stephenson's engine, constructed in 1829, was run at the rate of thirty-seven miles per hour, the exact time made by the fast-mail train from Philadelphia to St. Louis. Has speed in railway traveling reached its limit?

On the Vitality of Certain Land Mollusks.

[Read before the California Academy of Sciences by ROBERT E. C. STEARNS.]

I submit for the inspection of the Academy a living specimen of *Bulimus pallidior*, Sby., one of nine given to me by Prof. Geo. Davidson, who collected them at San Jose del Cabo, Lower California, in March, 1873.

These snails were kept in a box undisturbed until June 23d, 1875, when I took them out and, after examining them, placed them in a glass jar with some chick-weed and other tender vegetable matter, and a small quantity of tepid water, so as to make a warm humid atmosphere. This hospitable treatment induced them to wake up and move about after their long fast and sleep of two years, two months and sixteen days. Subsequently all died but this, which seems to be in pretty good health, though not very active.

It may be remembered that I mentioned to the Academy at a meeting in March, 1867, an instance of vitality in the snail (*Helix Veatchii*) from Cerros island, even more remarkable, the latter having lived without food from 1859, the year when it was collected, to March 1865, a period of six years.

The famous specimen in the British museum which is cited in the books, *Helix desertorum*, had lived within a few days of four years, fastened to a tablet in one of the cases, when discovered to be alive.

Helix desertorum, as the specific name implies, is found in arid and sterile areas, in the continents of Africa and Asia, and has, as will be perceived, a wide distribution. From the former continent, I have specimens from Egypt, and it also ranges through Arabia in the latter.

The *Bulimus* from the mainland of the peninsula of Lower California and *Helix Veatchii* from Cerros island, off the coast on the ocean side of the same, come from within the same physical environment, being only comparatively a limited distance apart.

Your attention is directed to the fact that the three species herein mentioned belong to geographical areas, which receive only a minimum rainfall, or in simple language, nearly rainless regions.

Within such areas vegetation is exceedingly limited even in favorable seasons, and the presence and growth of the annual plants is of course dependant upon the rainfall; this last occurring infrequently makes the food supply of land mollusks and other phytophagons or vegetable eating animals exceedingly precarious.

It is highly probable that a careful investigation in this direction will lead us to the conclusion that the land mollusks which inhabit these arid areas have, through selection, adaptation and evolution become especially fitted for the contingencies of their habitat, and possess a greater degree of vitality or ability to live without food than related forms in what may be considered more favorable regions, and through and by reason of their long sleep or hibernation, with its inactivity and consequent immunity from any waste or exhaustion of animal strength, are enabled to maintain their hold upon life when animals more highly organized would inevitably perish; and we are furnished with an illustration in the instances cited, how nature works compensatively, when we institute a comparison with the opposite conditions of activity, and the food required to sustain it.

The Generation and Characteristics of Smoke.

Mr. C. W. Williams says: So much has been said and credited on the subject of the burning and combustion, and even consumption, of smoke; and it has been so often asked, what is smoke? that the subject must needs receive some attention, and we therefore produce the following interesting facts for the benefit of our readers:

Before the characteristics of combustible gases were known, it was natural that all colored vapors, rising from heated bodies, should be called smoke. So soon, however, as the proportion of the several gases were correctly ascertained, through the researches of Davy and Dalton, the misapplication of the term became unpardonable on the part of those who profess to be public instructors on the subject.

The gas from which smoke proceeds, in a furnace or retort, is carbureted hydrogen. The constituents of this gas have been already described; each atom consisting of two atoms of hydrogen and one of carbon. This latter we are warranted in assuming to be a solid, contained and concealed from view, by or within the gaseous volume of the hydrogen, since carbon has never yet been produced in the form of a gas, nor hydrogen in that of a solid. It is only when their chemical union, in the form of the coal gas, is broken up, that the carbon becomes visible and tangible. Now this circumstance alone furnishes an unerring test of the difference between gas and smoke; a distinction which, we shall see, is capable of physical proof.

When we see a dark yellow vapor rising from heated coal, as at the mouth of a retort, or from a furnace, or domestic fire, after fresh coal has been thrown on, this color is not occasioned by the presence of carbon, but is caused by the sulphur, tar or earthy impurities which might happen to be in the coal. All these are subsequently separated from the carbureted hydrogen in the purifying process—the gas remaining transparent—so minute are the several atoms of the carbon, and so diffused are they when in connection with the hydrogen. That the solid carbon is there, notwithstanding this transparency, is proved by its subsequent liberation; as when a polished body is thrust into a flame of a candle or gas jet, and brought out with a deposit of the carbon on it. Carbon, in fact, when in chemical union with gaseous matter, is always invisible and intangible.

The separate characteristics of the gas and the smoke will be made clear from the following:

A tin vessel was prepared, in which was placed some small coal, resin and tar, to produce a quick and large development of gas. The lid was removed, and an iron, made red hot, was introduced, and the vessel was again close covered. A small tube was then inserted into the side of the vessel, to be blown into, as with a blowpipe, to expel the gas in a stream through a nozzle on the opposite side of the vessel from the blowpipe. That the carbon in this gas is inaccessible, is proved by presenting a sheet of paper to the stream, and, although it may be slightly stained, if there be much tar present, no carbon, however, will be deposited. On this stream of gas (many inches long) being lighted, a lurid flame will be produced, but which, becoming cooled down before it can be sufficiently mixed with the air, produces a large volume of true smoke. Here, then, is exhibited the gas, the flame and the smoke, at the same moment, and in succession, just as they are produced in the furnace—the gas being converted into flame, and the flame into smoke.

Now let us examine the characteristics of each. The carbon in the gas, as already mentioned, is inaccessible, being concealed by or within the atoms of hydrogen respectively, and cannot be separated, or deposited on the paper. On being lighted the hydrogen combines with the oxygen of the air, forming steam, which flies off, as already described. The result is, the liberation of the atoms of carbon, either to be converted into carbonic acid (if the heat can be continued) or deposited in the form of the fine lampblack powder, as we see it collected on the wick of the tallow candle. This may be tested by presenting the white paper to it, when a large quantity of this black carbon will be deposited on it. We here see the double error of mistaking smoke for gas, and then assuming that the former can be burned.

It may be well here to notice an error with which we are generally impressed, namely, that the cloudy volume of smoke, as we see it, issuing from a chimney, and filling a large space in the atmosphere, is formed of carbonaceous matter.

With equal propriety we might say, if we put a few drops of ink into a glass of clear water, and thus give it a blackened color, that the whole would become a mass of ink. This black cloud is merely the great mass of steam, or watery vapor, formed in the furnace, as already described, but colored by the carbon; and when we consider that no less than half a ton weight of water (in the expanded form of steam) is produced from every ton weight of bituminous coal consumed, we can easily account for the enormous volume and mass of this blackened vapor called smoke, as it appears to our vision, and the palpable error of supposing that this cloud of incombustible matter was capable of being consumed, or converted to the purpose of heat.

Were it not for this mass of steam the carbon would soon fall, as a cloud of black dust; but, being intimately and atomically mixed with the large volume of steam from the furnace, it is carried along by the atmosphere, only differing in color, like the cloud of steam we see issuing from the chimney of a locomotive when in action.

The Eureka and Palisade Railroad.

Advices from Eureka, Nevada, dated Oct. 22, say: The Eureka and Palisade railroad was completed to this place to-day. A large concourse of people were assembled on the depot grounds to witness the coming of the iron horse, which at 4:30 came in sight with the construction train. A general display of bunting was made throughout the town in honor of the event, and a warm welcome given the railroad by the citizens. At five o'clock a salute was fired at the depot grounds, and music by the bands enlivened the scene.

As the track-layers, locomotive and cars came in sight, the citizens organized an impromptu meeting on the platform of the depot, and George W. Baker was elected chairman. Congratulatory addresses were made by Hon. George W. Cassiday, Hon. Thos. Wren, Major John Dennis, and other citizens. The utmost good feeling prevailed, and the advent of the iron horse in our midst shows to all the faith our capitalists have in the permanency of our mines.

The road just completed is ninety miles long, and has been built mainly by Edgar F. and D. O. Mills, through whose indefatigable efforts Eureka is now in direct communication with the principal cities of the Pacific coast and the Eastern States. The entire cost of the road is over $1,000,000, all of which has been expended without any aid or subsidy from the county or State.

The Cry for Capital.

William Teal, our occasional correspondent, who gives a letter in another column of this issue, writes the following sensible letter to the Colorado *Mining Review:*

The cry for more capital for the development and working of mines has become so universal and importunate, it is well to consider at this time whether or not much of this clamor is not only unnecessary, but absolutely injurious to the best interests of the country, as well as to individuals. A common fault among Americans, and one to be much regretted, is that they must do things on a grand scale, or in other words, "they despise the day of small things." As soon as a mine shows a reasonable amount of evidence of productive value, its owners are agog, ransacking the world for money to build a mill or smelter that shall eclipse their neighbors; very often to affect this object they alienate a controlling interest in a really valuable property and place themselves helplessly in the power of sharpers who may or may not, according to their own will, deprive them of their remaining interests. Now, a man who has a gold bearing quartz lode that will yield an average of ten or twelve dollars a ton, or an argentiferous lode that will yield thirty dollars a ton, can place himself on the straight road to fortune, in rather a seemingly slow manner at first, but "slow and sure will win the race" to a certainty. A little one-mule arrastra, by selecting the best of the ore, will give a large margin over day wages. That soon by economy might be succeeded by a four-stamp mill, and so on *ad infinitum*, and this by keeping within the bounds of his own resources. But he had better not indulge in driving fast horses, and smoking fine Havanas before he gets up to a twelve-stamp mill.

A better style of arrastra, and costing but little more, it one has free water power, is the Spanish water power arrastra. This is run by a horizontal wheel under the bed or motor, and if properly constructed will work from two to three tons of ore of average hardness in twenty-four hours. These have been run for centuries in Mexico with great success, and in the saving of gold, nothing will ever be invented to excel them.

But most readers will say, how about smelting ore? We cannot avoid great outlay in building smelters! Yes, much of the present outlay may be avoided, and with the business on a pretty fair scale, too. The Mexicans, Spanish, and it is said by the Spaniards that the Romans used what they call the water blast. It may be possible that this has been tried in Colorado; I have never heard of its being tried in any part of the country. I have seen it used, and have used it myself successfully, and so can vouch for its efficiency. Ure's Dictionary of the Arts and Sciences, I think, contains a full description of its construction and use. But the one built by myself was according to the following description: First, a perpendicular chimney twenty-five feet high, a foot or so space inside, then a horizontal passage fifteen feet long connects with this at the bottom, with an outlet barely large enough for the water to escape; from this passage a small pipe runs to each cupola. Into the chimney about fifty miners' inches of water is discharged from a flume. The amount of air carried by the water made a strong blast, and copper and argentiferous galena ores are smelted successfully by it. One might suppose the vapor carried from the water would be a detriment, but such does not seem to be the case. The total expense for labor and otherwise did not exceed $1,000. Men who are willing to creep before they can run, may adopt simple appliances which will surely lead to better things.

Many notable instances of success from such small beginnings in mining pursuits might be mentioned, that have occurred within my knowledge in California, whereas great calculations and expenditures on equally valuable mines have been very often disastrous. Thousands of miners throughout the country are crying capital, who might go to work and grind out their capital much more expeditiously than they can procure it from any other source. That this course must be adopted is quite evident on a slight consideration. Demand for capital in mining has reached so extensive an area that if met it would absorb all the wealth of the nation. It is imperative that we must lower our ambition a little and be content to go more slowly. Indeed these small beginnings will be safer, surer, and more beneficial in their lasting influences. Men may say that the Mexicans are a slow people; that is very true, but we are a fast people, perhaps a little too much that way. With our impoverishment we can operate with their simple appliances and accomplish vastly more than they do.

FOR CARPENTERS.—The Omaha *Bee* says: "A flooring match took place last week between two carpenters, Tuttle and Simmons, at Clark & Kinney's new building, in Omaha. Tuttle laid nine squares (a square is ten feet square) and fifty-six and seven-eighths feet, and Simmons nine squares and forty feet, in one day." We knew a carpenter here once who laid eleven squares of flooring in one day, and was floored himself at night by a quart of whisky.

IT is calculated that there are 50,000 locomotives now in use all the world over, the United States numbering 14,200, England 10,900, Germany 5,900, France 4,900, Russia 4,600, Austria 2,400, Hungary 500, Italy 1,200.

MECHANICAL PROGRESS.

Frameless Houses.

While many changes have been made in interior decoration and convenience within the last few years, house building itself has not materially departed from the "balloon frame" method for a long time. Recently, a method of construction that dispenses with framing, boarding, lathing, and plastering, has been invented, and is already attracting some attention. By this method, the substructure up to the sill is prepared as for an ordinary wooden house. The sill is then placed, and firmly bolted down to the masonry. Solid wooden staves, 2½x4 inches, and of different lengths, are then prepared, and in each is cut a groove 1x1½ inch the whole length on each side. One inch holes are then bored through the sides at intervals of eighteen inches. These, with a number of iron rods, bolts, nuts, and tongues, make the entire materials for the house, except the ornamental work that may be put on without or within. Three staves, equal in length to the intended hight of the house, or the first story, if it is a high one, are set up outside of the sill, and firmly bolted to it. Between each piece is placed the iron tongue, reaching the whole length, and between the three are placed iron rods through the horizontal holes. Three more staves, each with its iron tongue, are then set up, and more rods are inserted, while those passing through the six staves are screwed up tight.

In this manner the entire exterior wall is set up. The tongues close the cracks tight, and the rods (arranged to break joints) hold everything firm and solid. For doors and windows, openings are left, to be closed and finished afterward in any style desired. The first floor, made of the same materials, is laid in the same way, and tension rods, secured to the walls, are placed below to give support and strength. The partitions are set up in the same manner, and over these the second floor is laid as before. The roof (of any pitch) is laid down in the same way, except that each stave is channeled, and each crack is covered with a half round cap to shed the rain. To secure the roof from spreading, tension rods are placed under the pitch, and fastened together by tie rods. Balconies, piazzas, and porches, made in any desired style, may be added, and all the ornamental work, base and weather boards, etc., be fastened directly to the wall. The iron work is designed to be galvanized, and all the bolts and nuts are countersunk. When tension rods are used under the floors, they may be bronzed, painted, or otherwise ornamented, or may be treated as part of the gas fixtures. By this method of construction it is seen that there is no lathing or plastering, no dead spaces in the wall for fire or rats to creep unseen in, no opportunities for the builder to hide poor work. All the material is visible, and the walls are alike outside and in. The exterior may be painted, and the interior oiled, varnished, or papered. The natural wood—spruce, pine, etc.—makes a good interior finish, and for seaside cottages, railway stations, and small churches, varnishing would be sufficient.

A building of this character can be erected in forty days after the substructure and cellar are ready—thirty days for getting out the materials, and thirty days for setting up. In cost, a saving of thirty-three per cent. is claimed over a frame building of the same size. For sea-side and summer houses, railroad stations, churches, etc., this method of building presents points of interest and value.—*Scribner.*

Heating Feed Water for Steam Boilers.—The *Railroad Gazette* has an article on "Heaters for Locomotives," with a full demonstration of supposing the temperature of feed water at 40 deg. Fah., the percentage of economy due to an increase of temperature of each 10 deg. (over the 40 deg.) derived from the heater is 0.85 of 1 per cent. If the heater could raise the temperature of feed water from 40 deg. to 200 deg., the total gain would be only 15.25 per cent. 10 to 15 per cent. of the fuel, and work in handling it, and especially 10 to 15 per cent. increase of power may be too great a gain to be overlooked: but when the cost and maintenance of the heaters, the liability to get out of order, the impairment of the exhaust, etc., is considered, "it is evident that a feed-water heater, instead of being economical, may be the reverse." These deductions apply to all boilers and engines, as well as to locomotives, although some of the conditions of application of heaters to stationary boilers are much more favorable for the use of heaters. It must be noticed, however, that under no circumstances can the percentage of advantage be greater numerically than is stated above.

To Drill into Hard Steel.—Make your drill oval in form, instead of the usual pointed shape, and temper as hard as it will bear without breaking; then roughen the surface where you desire to drill with a little diluted muriatic acid, and, instead of oil, use turpentine or kerosene, in which a little gum camphor has been dissolved, with your drill. In operating, keep the pressure on your drill firm and steady; and if the bottom of the hole should chance to become burnished, so that the drill will not act, as sometimes happens, again roughen with diluted acid as before; then clean out the hole carefully, and proceed again.

Burning Coal Dust.

The arrangements for manufacturing coal dust into fuel are now a practical reality. A new machine for pressing coal dust into fuel was recently put into operation at the Harrisburg machine shops, and a ton of solid coal was made in six minutes. The machine is said to be simple and universally practicable. Five new machines are now being made for this purpose. The Reading railroad company are about using this coal dust fuel in their locomotives. At Norwalk, Conn., there is a paper mill run exclusively by steam produced by burning coal dust, the refuse from coal yards, at a cost of less than $2.50 per day. Previous to using coal dust the cost of running by ordinary coal was $8.50 per day, and they have less trouble in keeping up steam under present arrangements than was encountered before making the change.

A New Hot Air Engine.—Another novelty in motors driven by hot air was exhibited in motion at the late fair of the New York Mechanics' Institute. It is described in the *Scientific American* as follows: It consists of two cylinders, one for power, under which the fire is built, the other simply for compression. The latter has a water jacket, and both cylinders have pistons, or more properly, plungers. The piston of the compression cylinder passes through packing at the top of the same, but below fits loosely in the bore, so that the air compressed is at liberty to pass up around the piston, and to enter a connecting passage, which leads it into the power cylinder, where it is heated and expanded, and so lifts the piston. As the two pistons are set on cranks 180 deg. apart, the down stroke of the power piston corresponds to the up stroke of the compression piston, so that the air, which just before has been expended, is now returned to be recompressed and again used. Thus the air is merely shifted from one cylinder to the other, and its cooling or heating is quickly accomplished through its being exposed to the action of the cold water or the fire in thin annular sheets. The machine (one horse power), we are told, burns very little fuel, one scuttleful answering for an entire day. The expenditure of oil is also very small. This seems to be a very simple apparatus, and one well adapted for a large number of light uses. It is almost entirely free from the disagreeable noise usually incident to caloric engines.

New System of Plastering.—Builders, owners, and tenants of city houses will doubtless view with interest a new system of plastering, which is claimed to prevent the sudden and disastrous downfall of ceilings, so frequently occasioned by defects in the water pipes and consequent leakage or overflow. The invention consists of replacing the scratch coat and brown coat used in ordinary work by the combination of fibro-ligneous sheets with a cement composed of lime, sand, and plaster. The sheets are of a fabric resembling coarse bagging, which is secured to the lathing, and the cement is supplied in the ordinary way. A hard finish coating completes the work.

Street Car Motors.—In Glasgow, Scotland, a new car, propelled wholly by compressed air, has withstood the prescribed tests, and is pronounced a success. There is now in full operation in New Orleans, a car using stored-up steam, replenishing the supply at stations along the route. The Glasgow car likewise has stations of supply, as have several in this country recently patented. It takes two minutes to fill. The car runs fourteen hundred yards at a maximum speed of twelve miles per hour. A large number of inventors are studying how to meet this great public want. Nearly every large city in the Union numbers one or more experimenters in the direction of engineering for street cars.

Belting in England.—The *Textile Manufacturer*, an English cotemporary, says that in some English districts belting is quite taking the place of gearing for driving purposes. In the neighborhood of Halifax alone, we learn, there are at the present moment about half a dozen mills being refitted. This change of fashion is giving quite an impetus to the manufacture of leather driving bands, and several firms, who hitherto have not attached much importance to that branch of their trade, have become quite alive to what is being done.

How to Calculate Centrifugal Force.—A correspondent asks of the *Scientific American*, "What will be the centrifugal force in pounds of ten iron balls weighing one pound each, attached to a wheel two feet in diameter and running at a velocity of 3,000 revolutions per minute?" That paper replies as follows: The centrifugal force in pounds is found by multiplying the weight of the body in pounds by the square of the number of revolutions per minute, and by the radius of the wheel in feet, and by dividing the product by 2,935.

An Electrical Engine.—A gentleman interested in navigation on the Hudson river is building a 500-horse power electrical engine, with which, it is said, he proposes to supersede steam on his line of boats.

Berlin Iron.—The fluidity of the Berlin iron, from which the finest and sharpest, although not strongest, castings are made, is attributed to the presence of arsenic in the iron.

SCIENTIFIC PROGRESS.

A New Mode of Measuring the Intensity of Light.

Various instruments for measuring the comparative intensity of light have been devised, but hitherto they have been all substantially on the same principle. Dr. Werner Siemens, however, has recently devised something entirely new, and which is much less liable to error than any device hitherto employed. His device depends upon the remarkable property which selenium has in one of its allotropic forms for conducting electricity better in light than in darkness. This conductivity increases in exact proportion to the degree of illumination present and the measure of the former thence is the measure of the latter. Hence, as electric conductivity can be accurately measured, so by this instrument can the intensity of light be accurately ascertained. In all other photometers the comparative degree of light can only be guessed at by comparison of the intensity of different shadows.

Selenium is closely allied in its natural history and physical and chemical properties to sulphur, with which it usually occurs. Like sulphur it exists in three distinct modifications or allotropic states. This element was first discovered as a reddish deposit in the leaden chambers employed in the manufacture of sulphuric acid from sulphur. When this deposit is melted and suddenly cooled it takes the form and appearance of a brilliant black solid, like black glass. If cooled slowly the same deposit becomes a dark gray, brittle, crystalline substance, with a metallic luster like lead. In its vitreous glass-like form it does not conduct electricity; but in its crystalline form it does away with the remarkable peculiarity above referred to of an increased conductivity, with an increase of the light to which it is exposed.

This has been found to be permanent; that is, no permanent alteration of conductive power ensued from exposure to light, and the selenium returns to its original condition of conductivity upon removal of the ray. Heat, also, is effective in influencing the conductive power, and the effect of the heat decreases as the temperature increases by some ratio not stated. The apparatus employed by Dr. Siemens, and which constitutes his photometer, he describes as follows:

At the bottom of a small tube, which can be rotated, is some of the crystalline selenium placed between two small, flat spirals of wire. The ends of the two spiral wires are connected with each other through a Daniell cell and the wire of a galvanometer. The needle is thus deflected. If I remove the cover of the tube, and admit the light of a gas-flame, whose strength I would measure, to the selenium disk, the conductivity of the disk increases proportionally to the intensity of the light; so the deflection of the needle becomes greater. If I now turn the tube so that it is directed to a normal candle, instead of the flame to be measured, and regulate the distance of this normal candle so that the deflection of the needle becomes and remains the same when the selenium is alternately illuminated by the flame to be measured and the normal candle, the light action is the same from both, and the intensities of the lights are accordingly in inverse proportion to their distance from the selenium plate.

Assuming the permanency of this property of selenium and the instantaneity of the recurrence of the change of conductivity, it would appear that we have at last an accurate register of comparative intensity, measurably, if not entirely divested from the effect of color, (which has impaired the visual methods,) and if the effect of heat can be diminished (or reduced to estimable comparative value); a perfect photometer, likely to supercede all other devices of this kind.

This discovery is too important not to command attention, and the further development will be looked for with the greatest interest.

Arctic Geology.—But little is known of the geological conditions of the Arctic regions, and it was first announced as a great oversight that the late British Arctic expedition carried no officers competent to investigate the great questions which are so intimately connected with rock-making in that part of the globe. It has since been announced, however, that Captain Feilden, the naturalist of the expedition, has in addition to studies in zoology, given considerable attention to palæontology, and especially to miocene remains. He has received instruction in the field work of the British survey, and we may now hope that the field of science which at the present junction may prove the most fruitful of all in northern regions, may in the end receive some competent attention.

Coloring of Birds' Eggs.—Mr. Sorby finds that the coloring of birds' eggs is due to the variable mixture of seven well marked coloring matters. The principal red coloring matter is connected with the hæmo-globin of blood, and the two blues are probably related to bile pigments. There appears to be no simple connection between the production of these egg-pigments and the general organization of the birds.

Webb's Famous Swim Scientifically Considered.

The *British Medical Journal* remarks: The unprecedented exploit of Captain Webb stands almost unrivalled as an instance of human prowess and endurance. It places Captain Boyton's achievement completely in the shade as an exploit, though its practical utility to the species may be much less. It is not merely that Captain Webb is a daring and accomplished swimmer, of unusual powers of endurance as regards sustained muscular efforts; the great question is, "by what arrangement or modification of his heat producing and heat-conserving processes did he manage to sustain his 22 hours' immersion?"

It is notorious that J. B. Johnson's attempt to swim the channel two years ago ended in complete failure after an hour's immersion; and yet J. B. Johnson is no ordinary swimmer, but a stalwart fellow, possessing good powers of endurance. There must exist in Captain Webb's case strong contractile power in the vessels of the skin, by which his body-heat was conserved, and his stores of force thus rendered available for muscular effort. Combustion within the body produces heat and mechanical effort, and when the powers are taxed to produce heat, or the temperature falls, muscular effort fails partially or absolutely. But, though weary, he fulfilled his task; and if his immersion be followed by no pyrexia (fever), then Captain Webb's heat-regulating powers must be regarded as of no ordinary character.

How far and to what extent the porpoise-oil prevented heat-loss, and so aided in the result, is a factor that can only be appraised when others have tried it, and seen how far it will enable them to undergo the heat-loss of prolonged immersion. That it will have an effect is certain, as in cold regions it is usual to grease the body thoroughly in order to retain its heat. But, admitting all this, there would still appear to be peculiarities in the vaso-motor nerves, which make the difference, and which have made Captain Webb's achievement *un fait accompli.*

The Acid of the Gastric Juice.—Whether the acidity of the gastric juice be due to lactic or hydrochloric acid is still an open question. The former view rests on the authority of Prout, Graham, Schmidt and others, while the latter is maintained by Bernard. Rabuteen has investigated the point afresh, employing a new method which he describes in the *Comptes Rendus.* He obtains the juice from the stomach of a dog which has been allowed to fast for twenty-four hours, and has then been fed on bits of tendon. To the liquid, after filtration, pure quinia is added so long as it will dissolve. It is then dried *in vacuo,* and the residue treated, first with amylic alcohol, then with chloroform or benzine; the latter agents being able to dissolve many salts of quinia, while refusing to take up the mineral chlorides. On evaporation, the solvent leaves a pure hydrochlorate of quinia. Other analyses showed the absence of any trace of lactic acid. Quantitative determinations yielded 2.5 parts of hydrochloric acid in 1,000 of gastric juice.

Counting the Blood Corpuscles.—A Monthyon prize has been given to M. Malassez for researches on blood. He has contrived an instrument said to be superior to those previously used for ascertaining the number of red corpuscles in a given space. It consists of a capillary tube, into which blood and artificial serum are introduced, and which is graduated so that the contents of a given length are known. The mean number of red corpuscles in human blood is 4,000,000 in each cubic millimeter. A greater number is found in small arteries than in large, and in veins than in arteries, and most in veins that have lost part of their serum by exosmose. They are fewer in cases of cancer and tuberculose. Lead poisoning also lessens their number.

The Oil Diagometer.—Professor Palmieri has discovered a new instrument which he calls a diagometer, and which is constructed for the rapid examination of oils and textures by electricity. What the apparatus will do, Professor Palmieri details thus: First, it will show the quality of olive oil; second, it will distinguish olive oil from seed oil; third, it will indicate whether olive oil, although of the best appearance, has been mixed with seed oil; fourth, it will show the quality of seed oils; fifth, finally, it will indicate the presence of cotton in silken or woolen textures.

The New Fossil Bird.—Professor Marsh has recently made a critical scientific examination of the fossil bird, discovered during his researches at the West, and which presents the phenomenal development of well formed teeth. The professor concludes that the creature was an intermediate form between the bird and the reptile, and that its discovery supplies one of the missing links in the Darwinian theory.

The Progress of Science.—An illustration of what has been done by Great Britain for the advancement of science and art may be found in the appropriations made for the public museums and art galleries in the United Kingdom, the amount paid in 1874 being $1,033,485.

Of the 64 elementary substances known to exist, 20 are quite rare and of but little or no practical value.

Sales at S. F. Stock Exchange.

The Mining Stock Market.

This has been anotber eventful week in tbo mining stock market. The series of disasters wbicb bave been visited upon mining stocks of late has ended in this iest calamity, the destruction by fire of the hoisting works of two of the most prominent mines and hurning of the mill aad batteriee of the Coneolidated Virginia and California. Thore are no two minee upon tbe Cometock that have occnpied such important relations to other minee as Ophir and Coneolidated Virginia. Tbe former wae developing into a firet-clase property, wbile it hae alwaya been a favorite for speculation, and tbrongb its shaft tbe Mexican and Union Consolidated were being prospected. The Coneolidated Virginia bae attained a world-wide celebrity for its wonderful hullion production and ite immense bonanza, and hae become perbape the most celebrated mine in tbe world. Witb new hoisting works, additional milling facilities and improved macbinery, tbo output has been increased of late and it was expected this month to tarn out two million dollars in ballion. The destruction of the worke, bowever, will retard mattere at tbe mine, aad it may even pase over the nenal montbly dividend of $10 per share, and uee the money for the purchase of new machinery. Tbe effect of tbe newe of tbe fire npon stocks was to deprese tbose et tbe Virginia end from twenty-five to tbirty-threeper cent., with the Gold Hill stock seiso affected, yet not sufficient to cause any alarm to their holders. California and Consolidated Virginia baye been favorite stocks for investments—the large dividends of tbe latter enticing many into the fold that formorly adjured stocks, while the drifts and winzes of the former bavo exposed such rich and large bodies of ore as to make it tbe richest known mine in tbe world, and on this account it was widely scattered, and held by capitialiste as well as by merchants and all classes of people in large quantitiee, npon whom this depreciation will fall beavily. Opbir, which sold on Monday at $52, sold for $38; Con. Virginia, $320, declined to $210, and California from $62 to $52¼—tbese were tbe lowest figuree reacbed in the morning hoard. Before tbe hoards entered into session it was reported that tbe San Frencisco board would bold no session, end that some of their membere were in negotiation witb members of the Pacific board to adjourn over, hut that the latter would entertain no such proposition. The San Franeisco board, at its convening, beld a private meeting, and the question of adjournment wae disoussed and decided in favor of tbe continuation of business.

When tbe boards met and the liet wae called, a terrific elanghtor was made. Whatever price wae offered was immediately accepted, the seller feeling asenred that he had made a good bargain. This state of affairs continned for some time after the morning sessione were ended, and when tbe rally came it was not so great a reaction as wae expected. The afternoon salee showed a better feeling, and this prevailed nntil late, when the news came that the Ophir shaft was on fire, wbich hed the effeot to immediately depress Opbir down to $34, and sent the Mexican and Union Consolidated tumbling after it to a proportionate degree. The last news may he said to have had the sevorest action of any npon the market, and had not nigbt closed tbe scenee there is no telling wbat figure tbis stock would have reacbed, eo great was the excitement. Tbe terrihle fire of 1869 in the Yellow Jacket, Crown Point and Kentuck mines, and the amount of damage done, bas not been forgotten, and tbie wae frequently citod by people when diecussiag the eituation.

Tbe rumors that the Ophir and Coneolidated Virginia shafte were on fire, and perbaps that of the Gould & Curry too, helped to hreak the market, and tbere wae a perfect panic. Many supposed that the brokere conld not stand the second onset, coming so soon after tbe financial panic, wben the Bank of California eusponded. Ae yet, however, no failures baye been announced, although the fail bas, no douht, seriously crippled many small operators. Tbe market bas slightly recovered in tone, hut prices are still very mucb depressed. If tbe two injured mines beve to sbnt down temporarily, as eome suppose, it will bave a further depreseing effect. Somo of the sbrewd onee took all the stock they could get at panic prices, knowing that they would realize good profite when tbe excitement wes over. Verily tbe stock deslers bave berd times of it lately, and they were just boping for hriek times when this disaster occurred. It sbowe, however, bow intimately the interests of San Francisco are connected with thoee of the mines, when an occnrrence of this kind influences it to such an extent. Tbose who are desirone of learning tbe details of tbe fell in stocks are referred to tbe nenal tables in another column.

MINING SUMMARY.

California.

AMADOR.

LINCOLN MINE.—*Ledger*, Oct. 23: This mine snspended operation some two weeks hack, and it wae tbongbt prohahle that active mining would not be rosumed before the commencement of the wet seaeon. On Monday last, bowever, a force of twelvo men were put to work taking out rock and repairing the shaft. Itie not likely tbat this number will he decreased. We understand that the mill will run on ten stamps whenever tbe limited eupply of water will enahle it to so.

ONEIDA MINE.—Amidst tbe paralysis of milling operations, in conecquence of lack of water, it is gratifying to be able to note that tbe Oneida company are working eixty stamps—the full capacity of their mill. They are running entirely by steam, and bave heen so rnnniog for more than a week.

EL DORADO.

AIDING BUSINESS.—*Republican*, Oct. 21: It ie expected that the ditch company will disbarse in the neighborhood of $60,000 here tbis month, and tbat in consequence we sball all he in easy circumstances, financially, ae nearly all of as ere intereeted more or less in theee payments. Tbis payment will hridge over the usual dullness experienced at this seaeon of the year, to a large extent.

FRESNO.

RICH QUARTZ.—Merced *Express*, Oct. 23: Cargyle & Co's mine, eituated ten miles north of Jones' storo and two miles eaet of Fine Gold gulch, Freeno county, is reported to he turniag out some as rich rock as any mine in tbis whole region of country. Tbe main sbaft is down 400 ft, and tbe vein at tbe bottom of tbe sbaft is four feet wide. Mr. T. B. Cargyle, of Plainsburg, who is the principal owner in the mios, informs us tbat the rock now coming from it will pay $500 per ton. If Mr. C. is oorrect, and tbe mine bolds out at tbie rate, it ie destined

to be the best mine on the Pacific Slope, not even excepting the great bonanza mines of Nevada.

LAKE.

QUICKSILVER.—Middletown correspondence of the *Bee*, Oct. 23: The Great Western is running three of Green's furnaces. At the Wall street one of Green's forty ton furnaces, with Winterburn's improvement, is being erected, and the Kearsage company have made arrangements to erect one of Neat's furnaces, such as used at the St. John's mine near Vallejo. The latter two companies will be in full blast by the first of December. The American mine is taking out about thirty flasks of quicksilver per month in their retorts. The Edith mine has just started up their new furnace and it is working quite satisfactory now. The owners of the Columbia and James mines are respectively prospecting their claims, and by another spring we anticipate lively times hereabouts.

NEVADA.

THE KENTUCKY.—*Foothill Tidings*, Oct. 23: Every foot westward in the drift on the 300-ft level of this mine, shows an improvement in the character of the rock and the general appearance of the ledge. Kentucky is destined to be one of the big paying mines of Grass Valley.

WOODPECKER ravine, just in the edge of our town, was a very rich surface diggings region and it is thought there must be a splendid quartz ledge in the adjacent hill. The Phœnix company are quietly exploring in that direction and with very encouraging prospects.

THE Smartsville company, whose new strike was chronicled last week, are creating quite an excitement down there. In quality and quantity the yield of their mine is said to exceed anything seen in those parts for many years.

THE ditch which will convey water from South Yuba to Bluo Tent, is expected to be finished early next week. It will be thirty miles long, and cost in the neighborhood of 20,000. It was commenced one year ago last spring, and has been pushed ahead as rapidly as possible.

A WORTHY object is that of the Accident club recently formed among the workmen at New York Hill mine of this place; it being to give certain amount of relief to its members, when disabled from work in the employ of the New York Hill mining company. Each member pays to the club, monthly, the sum of $1, and when disabled from work draws a benefit of $10 a week besides his medical attendance.

LAKE IDAHO.—The Idaho continues to be in a steady paying way, declaring regular monthly dividends.

CINCINNATI.—The Cincinnati is in an encouraging condition, and the owners, who are experienced miners, have no doubt about the ultimate success of the mine.

OMAHA.—The Omaha is having a crushing through at the Larimer mill, and the crushing will turn out well, according to the appearances of the plates and other amalgamating appliances at the mill.

NEW YORK HILL.—New York Hill continues to send to the surface very rich ore; so rich that it is boxed up and placed in a bank vault. The mill is meanwhile running on ore that will average well. The richest ore is from the low-level of the mine—the 500-ft. Ledge good thick.

PERSEVERANCE.—The Prospect company is working a ledge between Forest springs and Nelson ranch, called the Perseverance. The company are now timbering up the old tunnel and will soon be ready to take out quartz. Rock from this ledge has paid from $16 to $36 per ton. Perrin's mill has been engaged for crushing the Prospect company's quartz.

FRANKLIN.—The ore heretofore taken out of the mine paid $6,000 to 45 loads. The works are now down some 20 ft below where the rich ore was taken out, and the ledge looks as well as ever. A water wheel, or other machinery for pumping, will have to be put up before the miners can sink any deeper.

PITTSBURGH.—The Pittsburgh mine is looking unusually well. This mine is near Deadman's flat, southwest from Grass Valley, and is the Pittsburgh situated near Nevada City. The other day there was a crushing of 19 loads of quartz which gave about $900 in gold, or about $48 to the load. The sulphurets will raise the yield still more, because the sulphurets from the Pittsburgh are always rich.

EMPIRE.—The Empire mine, the oldest one now in the district which is being worked, still goes on full-handed and with good results. We are not able to-day to give full figures from the mine because we could not catch either the superintendent, Mr. David Watt, nor the foreman, Mr. James Bennalleck.

THE EBYEN PROCESS.—There are a great many here, which are rebellions in their character. These are awaiting the result of Mr. Ebyen's experimente with his new works. In many many days it will be known to all whether the new process can do what is expected of it. We believe that it will be a complete success and that the process of the reduction of gold bearing quartz will be completely revolutionized by it. We, however, are not speaking by authority, but say what we do say because appearances suggest the opinion. Speaking of the Dryer process reminds us to mention that it has been brought here from San Salvador, Central America, to be worked by that pro-

SIERRA.

NEW MILL.—*Mountain Democrat*, Oct. 16: A new mill, of 20 stamps, at the Independence mine, commenced crushing rock last week. The old mill has 16 stamps, making 36 in all. Jo. Carney is boss of the two mills, and under his able direction the ore will be made to yield large dividends to the stockholders. Geo. Black and A. Hart are working here now.

ALASKA.—The old Alaska mine, situated at Pike city, and now owned by Spencer & Brown, will, Mr. Spencer informs us, be in working order by the 1st of November. The mine paid well in days gone by, but was worked to such a depth that it would require heavier machinery than the company felt able to put in. The present owners are fitting up the works in the most substantial manner, and having fully explored the ledge know just what they have before them.

TUOLUMNE.

THE OMEGA.—*Independent*, Oct. 23: Superintendent Watt is driving ahead in the Omega Table Mountain gravel claim. The whole length of the tunnel is 781 ft. He has raised 34 ft by an incline to a rim or shore that divides the west channel of the mountain near the Alpha line and expects to strike into this channel at any moment. After intercepting this channel he will run a gangway 279 ft to the Alpha works, where Superintendent Collins left off, the Alpha company cleaning up at this point as high as 33 ounces. This is claimed by many to be the old original Caldwall channel with its pipe clay and black gold. Watt says if the water holds out for air blast purposes he will show some of the rhino very soon.

THE SPRING GULCH.—Superintendent Wm. Sharwood informs us that the Spring Gulch mine shows a vein of six ft. For the past twelve months they have been running through a slate horee the distance of 100 ft. They are working three men and a boy to the shaft and taking out rock enough to keep ten stamps going, at a distance of 200 feet from the tunnel level where they are at present drifting. All through this six ft vein sulphurets and free gold are visible and will mill about $25 per ton. This is one of the proofs that our mines require depth to be of any permanent value. The property is owned by Sharwood, Johns, Bawden & Co.

DITCHES.—Water in the Tuolumne hydraulic mining company's ditch is still running down hill, and will continue to furnish a supply for mining and city purposes until the last of November.

THE supply of water in the Tuolumne County water [company's ditches has about ceased, and will not be able to get the miners at work until the rain comes.

Nevada.

WASHOE DISTRICT.

OPHIR.—Gold Hill *News*, Oct. 21: Daily yield, 350 tons of ore. The ore breaste are all looking splendidly, and continue an uninterrupted yield of good ore, keeping mills crushing to their full capacity. The upraise above the 1200-ft level, is still looking splendid and holds out a fair promise of a strong upward continuation of the ore body. The main eastheast drift, on the 1100-ft level, is rapidly advancing, the ground in the face steadily growing softer with more and better indications of a near approach to the ledge.

JULIA.—The south drift on the 1000-ft level is steadily advancing, the face in soft porphyry mixed with streaks of clay. The prospect of encountering a body of quartz is much more favorable. The face of the main southwest drift on the 1400-ft level is rapidly advancing, having passed during the past week, through several small veins of quartz and ore averaging from ten inches to four ft in thickness, all of a very favorable character. The face of the drift is now almost entirely in quartz, and it cannot be long before the solid portion of the ore vein will be reached. The excavating for the 1500-ft station is about completed.

WOODVILLE CONSOLIDATED.—Cutting out of the pump stations at the 210 and 426-ft levels is rapidly approaching completion. The heavy stone foundations for the new and powerful pumping engine is well under way and is being pushed to completion as rapidly as possible. A large force of men are employed, and everything is being done to forward the work that apparently can.

CALIFORNIA.—The bottom of the winze below the 1550-ft level is still in rich ore. The face of the north drift on the same level is also in good ore. The winze being sunk in cross-cut No. 5 below the 1500-ft level is down 15 feet, the bottom still in rich ore. The face of the main north drift on the 1500-ft level is still in ore of a fair milling quality, although not of as rich a quality as that heretofore encountered. The opraise from cross-cut No 2 on the 1400-ft level has been connected with the 1300-ft level, greatly aiding the ventilation in that portion of the mine.

CONSOLIDATED VIRGINIA.—Daily yield, 650 tons of ore, keeping the mills running up to their full crushing capacity. The ore breasts continue to look finely and yield well. A large amount of winter supplies, in the shape of wood, timbers, etc., are being laid in, to provide against the slow and expensive transportation of such things in the winter season. Sinking the C. and C. shaft is making rapid progress. It is now down 730 ft, the bottom in good sinking ground. The new hoisting engines are about completed, ready to start up. The main hoisting works building is completed.

BELCHER.—Daily yield, 180 tons of ore. The ore breasts are looking finely, and the yield can be easily increased to 350 or 400 tons per day whenever the crushing capacity of the mills will warrant it. The mine can easily net from $40,000 to $70,000 per month for a year or more to come. The water is drained from the main incline below the 1600-ft level, and the incline is being repaired in places where the water had caused a slacking of the rock and swelling of the timbers.

NEW YORK CONSOLIDATED.—The splendid and powerful new works are now in full operation, raising the water from the shaft at a very lively rate. It is already reduced to the second station or 200-ft level, and 200 ft more remains to be taken out in order to reach the bottom of the shaft. This will take about two weeks, and when done sinking will be actively resumed under the most favorable auspices.

CHOLLAR-POTOSI.—Sinking the new combination shaft is making rapid progress, the rock in the bottom blasting out finely. At the old shaft the usual amount of ore per day—50 tons—is being extracted from the old upper workings, and the three main south drifts on the 1150, 1250 and 1350-ft levels, are being steadily advanced.

SIERRA NEVADA.—Sinking the new shaft is going on steadily forward at the usual rapid rate. The main west drift on the 1000-ft level is being steadily advanced. The new drills and other machinery is all working splendidly.

LADY BRYAN.—Sinking the main shaft is making steady progress. The face of the west cross-cut, from the south drift, on the 380-ft level, is showing considerable improvement. The southwest drift, from the old shaft, on the 170-ft level, has been again started up, and being pushed farther to the southward.

OVERMAN.—The water has been drained down to the 1100-ft station, which is now about sufficiently clear to permit of a resumption of work on that level.

EUROPA.—The west drift at the 320-ft level is in a distance of 95 ft, the face in very encouraging ledge matter. During the first part of the week a fine seam of clay 3 ft in thickness was encountered. This clay has the regular Comstock dip to the east and begins to look as though the drift was gradually nearing the ledge.

COSMOPOLITAN.—A raise is being made to connect the 2 tunnels for ventilation purposes, and some very good ore is found in this raise, it being in the regular vein itself.

IOWA.—The main west drift at the 450-ft station is evidently approaching the main ledge, the stringers of quartz and ore coming in quite frequently, and of a very encouraging character.

BEST AND BELCHER.—Cleaning out and retimbering the south drift from the winze on the 1700-ft level is making slow progress on account of the intense heat.

SAVAGE.—Driving the main north drifts on the 2100 and 2200-ft levels going ahead as usual.

SILVER HILL.—The cross-cut at the 4th station is steadily advancing toward the ore vein, the face in soft working ground.

BUCKEYE.—Owing to the breaking of a shaft, nothing has been done in the mine for the week past.

LADY WASHINGTON.—The new works are about ready to start up and will do so very shortly, when the shaft will be freed from water and sinking resumed under flattering auspices.

MINT.—The bottom is still in ledge matter of a very favorable nature. The flow of water is slight.

GOWN POINT.—Work is going ahead as usual at all points, the machinery working well, and the prospects hopeful.

PROSPECT.—Work in both shaft and drift going ahead lively with fine prospects, and the new hoisting works pushed toward completion as energetically as possible.

UNION CONSOLIDATED.—The main north drift on the 1300-ft level continues to exhibit excellent indications of ore.

KNICKERBOCKER.—The repairs to the foundation and machinery are nearly completed, ready to again resume work in the shaft, as soon as the water is extracted.

MEXICAN.—Sinking the winze below the 1465-ft level, as usual.

JUSTICE.—The splendid body of ore at the 600-ft level of the old south mine continues a still better showing with each foot of development.

ORIGINAL GOLD HILL.—Work is resuming on the north drift, the new blower operating to very good advantage. The south ore body is looking finely.

GLOBE CONSOLIDATED.—Driving the north and south drifts on the ore vein at the 350-ft level, with some very favorable indications of ore.

LEO.—The prospecting drifts from bottom of the winze, 225 ft below the main tunnel level, are being steadily driven ahead in good working ground, and good progress is being made. The face of the drift is still in very much better of a very favorable character.

GOULD & CURRY.—The main incline has been sufficiently retimbered to admit of the passage of the incline car down to the 1700-ft level, and retimbering the main north drift on that level has been resumed.

YELLOW JACKET.—The east cross-cut, near the north line, on the 1740-ft level, has passed into a very favorable change of ground, with some excellent ore prospects.

HALE & NORCROSS.—The prospecting drifts on the 2200-ft level have not made any valuable or important developments during the week.

DAYTON.—Sinking the main shaft is making the usual good progress, the rock in the bottom working quite soft. Matters about the mine are fast assuming a shape that must soon admit of new and important developments in the mine.

BALTIMORE AND AMERICAN FLAT.—A small amount of very fine ore is being hoisted from the old workings on the 400-ft level. This ore will work at least $100 to the ton, and we hope is but the precursor of much larger quantities to come in a very short time.

BULLION.—The new combination drift on the 2000-ft level of the Imperial is steadily advancing. The main north drift on the 1700-ft level of the Imperial is steadily advancing along the west wall of the ledge, the face in quartz and ore mixed with porphyry.

IMPERIAL-EMPIRE.—Daily yield, 40 tons of ore. The ore breasts continue to look well and yield the usual amount of good milling ore.

NORTH CONSOLIDATED VIRGINIA.—The flow of water is light, and with the aid of a new iron tank for hoisting, which has just been placed in the mine, the flow of water for twenty-four hours can be hoisted out in about one hour's time.

FLORIDA.—The main west drift is evidently about to enter the ore vein itself, judging from the rich assays obtained, some running as high as $2000 to the ton. This was from pieces of ore washed out by the great rush of water tapped in opening the east wall of the ledge. The prospects for a bonanza in the Florida are very flattering.

ROCK ISLAND.—The 650-ft station is completed, and a drift started to cut and prospect the ledge. The water has retarded the work considerably.

SULLIVAN.—The shaft still continues in the excellent vein material mentioned in our last report. It is fully thirty feet wide, and is an important development.

SUTRO TUNNEL.—Ground at face of header very soft and treacherous, having to be lagged and otherwise supported very promptly and carefully as fast as any advancement is made, in order to prevent accidents. These soft streaks of dangerous ground are very liable to be met with at any time. Total length of tunnel to-day, 11,220 ft.

ELY DISTRICT.

BULLION SHIPMENTS.—White Pine *News*, Oct. 23: During the week the Eberhardt and Anrora company shipped twenty-five bars of bullion, valued at $35,986.06. The Shoba mill shipped one bar, valued at $1,299.47.

LOCAL ITEMS.—The regular amount of work goes on with indications of renewed activity in mines now idle as soon as necessary arrangements are completed. Considerable outside work is being done in anticipation of a break in the weather before long. The locomotive will probably make its appearance at this end of the line about the 30th, the contractors for repairs of the railroad being almost through. The shipment of bullion for the week ending October 23d, is $32,184, a slight increase over last week's amount.

RAYMOND & ELY.—Regular quantity of ore daily taken out, same grade as heretofore, considerable of the lower grade being sent to Salt Lake and yielding good returns.

ALPS.—During the past week have been hauling ore to the Floral mill, and yesterday crushing was commenced; the results we will get next week.

FLORAL MILL.—The Floral mill has been running steady the past week; have worked 100 tons for the Raymond & Ely, and is now working on Meadow Valley and Alps ore, with plenty of ore on hand to keep them going for some time.

NEWARK MILL.—The Newark mill was closed down Tuesday last, and will not commence operations until the superintendent, F. Clute, returns from San Francisco; in the meantime the ore is accumulating at the mill.

Utah.

STOCKTON MINES.—Cor. Salt Lake *Tribune*, Oct. 22: The mines of this district are principally located in Silver canon and Spring gulch, within a radius of 2½ miles of Stocktou. Many of them are located by the soldiers of General Connor's command, and "old titles," as a matter of course, abound to some extent. Developments have not been carried on to the extent that the merits of the district would seem to justify, yet considerable has been done, and a great deal more will be done during the coming year. In Silver canon, a short distance from its mouth, is located Lucky Boy No. 2. In this instance there is something in a name, for it has proved a decidedly lucky strike for its fortunate owners this season. It has an incline down about 60 ft, on a vein averaging over 3 ft in width, of galena and carbonate ore, assaying 10.69 ounces in silver and 80 per cent. in lead. The vein appears regular in its course, and has improved as depth has been attained. The owners, Messrs. Davie, Tate and Vaughan, have done their own developing under many discouragements and disadvantages, and are now reaping the rich reward of their perseverance. Regular weekly shipments are being made to the Chicago smelter, where the ore is regarded as being among the most desirable and easily worked in the district.

NEARLY ALL TOLD.—The Order has now been established in forty-seven of the fifty-three counties in California. The only counties in the State now without a Grange are Alpine, Klamath, Mariposa, Mono, Trinity and San Francisco.

THE Grinter Brothers, of Bolinas, are just completing a large trout pond at the head of the bay. It is 100x180 feet, and about five feet deep. The bottom is composed of a clean gravel well adapted to fish.

Government Tests of Beams, Girders and Columns.

A committee of the United Statea Board, appointed to test iron, steel and other metals, hes been instructed "to arrange and conduct experiments to determine the laws nf resistance of heams, girders and columne, to ohange of form and to fracture."

This committee, desiring to attract to this hranch of the inquiry the hest talent and experience of the conntry, in order to reach results of the greatest practical value, solicits the aid and co-operation of all who msnufacture or use heams, girdere or columns.

Many experiments have been made hy the rolling mills engaged in the manufacture of wronght iron heams, the results of which have, dnnhtless, heen carefnlly recorded and tahulated. The committee earnestly asks copies of euch records and tahles. Engineers, architects and mannfacturers, have also made many experiments upon cast iron heams and riveted wronght iron struts and girders, the reaults of which are respectfnlly requested hy the committee.

It is desirable that information as fnll ae may he ohtainahle, with reference to the constitution and mannfacture of the iron used in making the pieces tested, should accompany reports nf experiments, especially chemical analyses of the metal, where tbese have heen carefully made.

The proporlions of the various parts of the semples tested should he exactly given; and in all riveted work the size and position of the rivets shonld he clearly set forth. In all cases the modes of applying and measuring the strains shonld be given.

Accnrate cross sections of the samples tested, drawn to ecsle, large enough to admit of reliahle measnrements, will greatly facilitate a proper nnderstanding and analysis of the re aults.

During the constrnction of the machinery ordered by the board, the committee desires to collect information as above, and to make snch experiments ae seem practicahle hy the use of dead loads. For these experiments, and for those which will he made when the machinery is ready for use, mannfacturers are asked to snpply such hesms, girders and columns aa they may desire to have most carefully and im partially tested.

It may he of interest tn those who are thus asked to contribnte costly articles for destruction hy tests, to he informed that the machinery ordered is believed to he the hest yet designed for testing purposes, and to possess all the nicety and accuracy attainahle with the present knowledge of machine conetruction. The first machine will have a capacity of 400 tons (800,000 lbs.); and this will he replaced hy another of 1,000 tons (2,000,000 lbs.) capacity at an early day.

All snggestions as to the kind of tests to he made, and tbe manner of making them, calculated to give them the greatest practicsl valne, will be gladly received; and for these and all other assistance rendered, proper acknowledgements will he made.

Sample heams, girders or columns, furnished for test, should he stamped at one end with a distingnishing nnmher, trade mark and initials of the maker, and forwarded to Col. T. T. S. Laidley, President of the Board, at Watertown Arsenal, Watertown, Massachusetts.

Reports of tests already made, and all other information herein asked for, may he forwerded tn the chairman of this committee, at Maywood, Illinois.

Wm. Sooy Smith, O. E., *Chairman, Maywood, Ill.*

Mussels on the Great Eastern's Bottom.

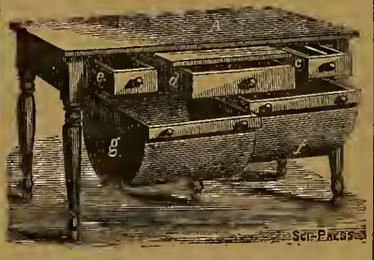
Henry Lee writes in *Land and Water* concerning an examination he has made of the bottom of the Great Eastern: "There were traces of a few harnacles near the level of the water line, especially ahont the atern post, and hetween it and the rndder, and the latter itself, ae well aa the propelling screw, was covered with the common acorn harnacles or "chitter;" hut all the rest of the hull nsually submerged was clad with an enormous mnltitnde of mnssels, clustered together in one dense and continnous depoait extending over a surface of 52,000 square feet nf iron plates, and in some parts six inches thick. Mr. Beckwith had made a oalonlation, which I was ahle to verify with him, of the total weight of the mnsels thns accumnlated. It was found hy careful experiment that the average weight of those on each square foot was from twelve to thirteen ponnds; therefore the vessel was encumhered with not less than 300 tons of living marine animals adhering to her—mnssels enough, in fact, to load witb full cargoes two ordinary collier hrigs. Although the mere weight of this mass would not, perhaps, mnch affect the huoyancy nf a vcasel of 25,000 tons burden, it will he readily understood that the friction of such a rough, jagged incrustation paesing through the water would materially diminish her speed. As those troublesome adheronte were scraped off with shovels hy workmen employed under contract to remove them, they were carried away hy cartloads and hoatloads and hurried along the shore of the haven. In some localitiee they wonld have heen heartily welcnmed hy the fishermen as valuable bait."

A Handy Kitchen Table.

We are certain that the ahove line will attract the attention of those of the gentler sex who are interested in domestic affairs; for "a handy kitchen table" is something not seen every day or in every house. A kitchen table is generally as plain and nnornamentel a thing aa can he conceived, with a little hit of a drawer jnst big enough to hold a cork screw, some clothes pins, pieces of string and perhaps an apron. In effective contrast with a table of this kind may be placed that which is represented on this pege hy the engraving.

As any one can see at a glance, this is one of the most convenient articlea ever presented to the housekeeper. While it is an ordinary kitchen table, it is at the same time a complete closet, as a reference to the cnt will show. *A*, is a general view of the table; *b*, a kneading board, which slides under the top of the table; *c*, a drawer, with spaces for rolling pin, yeast powder, spices, etc.; *d*, and *e*, two drawers for knives, table cloths and general purposes; *f*, and *g*, two convex drawers for flour and meal, each drawer holding 50 pounds.

This gives a closet complete in a table; at the same time it is neat, light and strong. It will save many tiresome steps in the preparation for haking, for instance: First for your kneading hoard, which is no donht split by the falling of a nail, or hy heing hid in the corner of a cloact; then again, for the rolling pin, which the children have had to play with, and left, no one knows where; then for your flour, which is in a sack, eaten up hy the mischievous mice, and the flonr scattered over the floor, or in a hox or harrel, in a distant closet; then for yeast powder and spices. Therefore, with the many steps you have to take in your preparations, yon are tired ont hy the time you are ready for your haking, and thereforo your "dear Hubby" hes to take a short allowance of pastry; hut hy having the "household treasure," all this running and fretting is done away with, as yonr flour is in nice, convenient, mice-proof drawers, yonr kneading hoard al-



C. H. Townsend's Improved Kitchen Table.

ways in its place, clean and sound, yonr rolling pin and spices at your elhow, so tbat you do not have to take a single step in your preparations for haking. These tables are mannfactnred and sold hy E. Hook, 1067 Broadway, Oakland, and also hy John West, 328 Pine street, San Francisco.

Anonnn the World in Eighty-eight Days Jnles Verne's delightful romance, entitled: "A Tonr of the World in Eighty Days," may soon he rewritten with a snbstential hasis of fact to give it additional interest. The *United States Mail*, a jonrnal devoted to postal matter, tells of a gentleman residing in the suburhe of New York, who recently made an experiment with a view to ascertain how long it takea a letter to travel round the world hy mail. He addressed a letter to the United States postal agent at Yokohama, Japan, marked it "*via* Brindisi," and dispatched the same hy steamer leaving New York for Sonthampton, England, on the 13th of May last. The letter inclosed another, addressed to himself, at New York, which he requested the postal agent at Yokohama to forward to the United States, *via* San Frsncisco, hy first steamer. The letter arrived in England on May 24th, and was thence dispatched hy way of Brindisi, Aden (*via* Suez), Ceylon, Siugapore, and Hong Kong to Yokohama, arriving there July 11th. From there the enclosed letter (addresaed to the writer) was forwarded by steamer leaving Yokohama on Jnly 12th, and arrived at San Francisco July 31st; left San Francisco Angust 1st, and reached New York Angnst 9th, having accomplished ita circumferential journey in exactly 88 daya.

Brimstone Works.—The *Silver State* saye: G. W. Meacham, of the Humholdt house, informs ns that Hale & Duffy and F. J. McWorthy & Co., the two companies who own the extensive snlphur deposits at Rahhit Hole, are making arrangements for refining the crude sulphur at the mines. Hale & Duffy have the material for refining works at the river, and McWorthy has just received two large retorts, each several tons capacity, and a lot of other castings and machinery for running the works. He has also brought six large wagons and teams from California to be used in hauling the hrimstone from the mines to the railroad. The demand for thie article is in excess of the supply, and it appears that the Rahhit Holo depoaits are the most available on the coast. A great many teams are employed at the present time in hauling the ornde snlphur tn the railroad, eight nf which, heavily loaded, arrived at the Humholdt hnuse yesterday,

The Microscopical Society.

The regnlar meeting of the San Francisco microscopical society was held on the 21st inst., President Ashhurner in the chair.

Mr. J. Edwards Smith, of Ashtabnls, Ohio, was proposed for corresponding membership.

A portion of the snrplus finds of the society has heen devoted to the purchase of hooks, and it is the pnrpose of the members to have, as soon as possihle, a complete library of microscopical literature. The corresponding secretary, Mr. Hanks, announced the receipt of eight volumea of "*Science Gossip*," twenty-two volumes "*Quarterly Journal Microscopical Science*," aud thirteen volumes of "*Popular Science Review*." There were also received by subscription the last nnmhere of *Grevillea*, *Journal Quekett Microscopical Club*, and *Monthly Microscopical Journal*, and hy donation from the publishers, the Octoher nnmher of the *Overland Monthly*.

The object cabinet waa most handsomely enriched hy donations both great in numher and variety.

Mr. Ashburner started out with a presentation of twenty-seven slides, mounted hy him with diatoms from as many localities, mostly from earths sent the society hy Mr. Arthur M. Edwards, one of the society's corresponding membera, and this was followed by the donstion of five slides of rock sections, by Mr. Attwood, from the foot wall, hanging wall and "horse," met with in the Gold Hill end of the Comstock voin, at a depth nf 1,400 feet. Mr. Attwood promised, also, to present an additional nnmher at the next meeting from the north end of the vein, and he will then accompany the same with a paper whicb will, no donht, he very interesting and useful in its suggestions.

Mr. Kinne donated a slide mounted hy him with specimens of the *Phylloxera vastatrix*, now heing cultivated in this State, under protest, and exhibited from his cahinet a slide mounted hy him, with a nnmber of insects commonly known as the "wooly louse," which infests the pear and other trees.

The great similarity hetween the two was noted, and particularly in the construction of the proboscis. Dr. Burgess handed in a slide which he had monnted with a portion of psuedo membrane from the intestinal canal, and Mr. J. P. Moore added to the list in the way of a slide mounted by him with a transverse section of *Myrica Californica*, California myrtle, and two, with both transverse and longitudinal sections of *Pachystima myrsinites*, or false myrtle.

Mr. Ewing presented a material for mounting, and sand from Feather river, Plumas county, Cal., showing quartz crystals, and Mr. Henry Edwards added to the cahinet some thirty species of lichens from various perts of Australia.

Dr. Harkness exhihited a hoantiful specimen of *mucorini*, growing npon a variety of the capsicnm. Long silvery filaments were attached to the substratum hy root like hranches, each snrmounted by a globular sporangium, which were filled with innumerahle spores. The mucorini may be found in great abundance at this season of the year on any decaying fruita and vegetahles, in whitish tufts, which tnrn hlack at maturity.

Dr. Harkness also exhibited the apormagonia of a new variety of *Puccinia*, found on the *Darlingtonia Californica* (specimens of which were exhihited at the late Mechanics' fair), and which appeared in dark hrown spots on the surface of the plant, and was shown hy a vertical section through the leaf. The spermagonia was run in nrn shaped receptacles hetween the cell structures, the receptaclea heing filled with exceedingly minnte threads, which force their way through the epidermis of the leaf. The hottom of this receptacle is covered with short mycelial hranches, from the ends of which are detached numerous very small spore-like hodies—*spermatia*.

Humholdt District.—The recent discovery of a rich lead in an old tunnel in Humholdt district hy the Knnkel Brothers, is creating much excitement among mining men. W. A. Bolinger and other good judges, who have heen to see the lead, pronounce it rich heyond question, and bring specimens of the ore in which free gold abounds. Several mining men from California who have heard of the strike are now in the district looking at the ledge and taking observatione in ita vicinity. There are many ledges cropping out in the district, some of them twenty or thirty feet wide, and none of them prospected to a greater depth than ten or fifteen feet from the surface. The discoverers of those mines had the tunnel fever hadly, and expended mnch lahor in boring into the sides of the monntains, hut ahandoned their holes before striking the leads they were started to reach. Thia new strike will nndoubtedly cause a reaction, and several companies are now arranging to commence work on the most promising of those ahandoned claims.—*Silver State*.

The Winn-Storm Accident which canaed the partial destrnction of a portion of the framework of the Agricultural hall on the Centennial gronnds recently, it is reported will cause but comparatively little incouvenience, as the huilding, which is to he of wood and glass, in a seriee of Howe trnss eashes of Gothic form, is capahle of erection in two or three months,

Calaveras County Quartz Mines.

Notwithstsnding the fact that the scaroity of water in a great measure impedes active operations in quartz mining, that hranch of industry was never in a more promising condition than at preeent. All through the npper country—especially in the Mosquito, Weat Point, Jesus Maria and Washington districts—more favorahle developments have been made the present season than in any previons yesr, and the results of operatione have heen more remunerative. Capital has taken a very active part in bringing about a hetter condition of affairs in this county, as regards quartz mining, and the fact that investments are in a msjority of instances proving profitable will stimulate further research and development. No county in the State stands better to-day, as a promising field for engaging in mining ventures than Calaveras, and the good showing now heing made will still further tend to attract the attention of moneyed men. What makes Calaveras more than ordinarily attractive to those wishing to engage in mining enterprisea—aside from the fact that the representative miuee of the county are paying well—is the large area of unoccnpied gronnd carrying gold hearing ledges. There is ahundant opportunity for locating and prospecting unclaimed veins, if parties prefer that method, or partially developed ledges can he purchaaed on favorahle terms. The quartz helt of this county—extending from the Mokelnmne on the nortb to the Stanislaus on the south—is fnlly twenty miles in width, and nearly the whole of that area is checkered with veins of gold hearing rock. The fact thst new discoveries are constantly heing made, in addition to the great number nf mines being profitably worked, is ample evidence both of the magnititude of our mining reaources and the fact that they are yet comparatively undeveloped. There is no qnestion but thst Calaveras offers hetter inducements for the prosecution of quartz mining than any nther section of the State, and that fact is acknowledged and appreciated by those who havo the energy, enterprise and capital necessary to engage in the business. Men of means are not slow in availing themselves of such advantages as are offered hy this county, and the consequence is that many of our minea are passing into hands that can combine capital with lahor in developing them. The present enforced inertness, consequent npon the lack of water, will be followed by increased activity with the first rainfall, and there is every indication that the coming season will mark extensive and remunerative quartz mining operations.—*Calaveras Chronicle*.

Manufactnae of Paper.—Of tbe 1,300,000,000 human heings inhahiting the glohe, 360,000,000 hsve no paper nor writing materisl of any kind; 500,000,000 of the Mongolian race nse a paper made from the stalks and leaves of plants; 10,000,000 nse for graphic purposes tablets of wood; 130,000,000—the Persiaus, Hindoos, Armenians and Syrians—have paper made from cotton, while the remeining 300,000,000 use the ordinary staple. The annnal consumption hy this latter number is estimated at 1,800,000,000 pounds, or an average of six pounds to the person, which has increased from two and a half ponnds during tbe last fifty years. To produce this amount of paper 200,000,000 pounds of woolen raga, 800,000,000 pounds of cotton rags, hesides great quantities of linen rags, straw, wood and other material, are yearly consnmed. The paper is manufactured in 3,060 paper mills, employing 90,000 male and 180,000 female lahorers. The proportionate amounts of the different kinds of paper are stated to he: Of writing paper, 300,000,000 pounds; of printing paper, 900,000,000 pounds; of wall paper, 400,000,000 ponnds, aud 200,000,000 pounds of cartoons, blotting paper, etc.

Rich Strike in the Fourth of July.—For some time tho Fourth of Jnly mine, at tbe head of New York canon, has heen showing exceedingly well, hut not nntil yesterday was the real marrow of the honanza reached. Contractor Thomas, we learn, has, by his well directed efforts, placed the mine in an enviable rank as one of the most promising in the whole district. Yesterday in the forenoon a small streak of heavy black metal came in at the bottom of the incline, and hefore night it had increased in width to twelve inches. The black metal on all points on Prospect mountain is very rich, going high up into the hundreds per ton, and the present indicatinns are that the Fonrth of Jnly has an ahundant supply of it. The Fourth of July is owned principally in Carson hy Judge Hilliyer, Ahe Drieshach, Jndge Whitman, Buel Davis, John Neil, Mr. Gardner and perhaps some others, all of whom we congratulate on the improved prospects of their Base Ring honanza.—*Eureka Sentinel*.

Big Teams.—More hig qnartz teams are at present to he seen on the streets of Virginia and Gold Hill than at any time during the past three or four years. Owing to the low stage of water in the Carson river many stamps in the quarter are idle, thereforo teams are in demand to haul ore to ontside mille—that is to mills on the line of the Virginia and Truckee railroad. It looks like old times to see the huge wagons with their "hack-actious" and their twelve, fourteen and sixteen mules rolling along the streets. We miss the jingling of the hells, however, that was heard in the daye of the mountain schooners.—*Virginia Enterprise*.

Useful Information.

Effect of Magnetism on Watches.

A correspondent of the *Scientific American* writes as fellews: A few weeks ago my watch for the first time in ten years, refased to go. Up to then it had kept correct time, and was then in good repair, having been recently cleaned. When it first began to stop I would start it by the key, and it would sometimes run a day; but finally it stopped entirely. I had it carefully examined by an expert, who, although he could find no cause, failed to make it run even for an hour.

I am running at my works a powerful magneto-electric machine for depositing copper; and having noticed that I could magnetize a piece of soft iron at a distance of at least six feet from the machine, so that it would lift and support the weight of a large nail, I became impressed with the idea that some of the steel parts of my watch had become permanently magnetized; so I made a watch repairer take it apart. Having some fine soft iron filings, I dipped the balance wheel, escapement wheel, lever and hair spring into the filings; and each piece raised up at least one-half its own weight of the filings, showing all the polar characteristics of the particles.

I have read of watches being spoiled by magnets, but had no idea that it was unsafe to go into a room containing a magnet.

The watchmaker thought he might "brush it off" for about a dollar. I let him brush on it three days as a lesson in magnetism, and then told him that nothing short of heating it red hot would demagnetize it. He put in new parts, including a new mainspring, which was also infected, and the watch now runs as well as ever.

Common Sense Ventilation.

The best practical statement I have met about ventilation, says Col. Waring in the last *Atlantic*, was contained in the remark of a mining engineer in Pennsylvania: "Air is like a rope; you can pull it better than you can push it." All mechanical appliances for pushing air into a room or a house are disappointing. What we need to do is to pull out the vitiated air already in the room; the fresh supply will take care of itself if means for its admission are provided.

It has been usual to withdraw the air through openings near the ceiling, that is to carry off the warmer and therefore lighter portions, leaving the colder strata at the bottom of the room, with their gradual accumulation of cooled carbonic acid undisturbed. Much the better plan would be to draw this lower air out from a point near the floor, allowing the upper and warmer portions to descend and take its place.

An open fire, with a large chimney throat, is the best ventilator for any room; the one-half or two-thirds of the heat carried up the chimney is the price paid for immunity from disease; and large though this seems from its daily draft on the wood-pile or coal-bin, it is trifling when compared with doctor's bills, and with the loss of strength and efficiency that invariably result from living in unventilated apartments.

Ornamentation With Autumn Leaves.—A very pretty way to ornament any plain article of furniture, a cabinet or panelled trinket cupboard, boxes, jars, trays, etc., is by the following simple process: Having collected the ferns and leaves in all their endless variety, prepare them thus: Lay the leaves one by one on a piece of soft paper, wrong side up, and with a sharp pen knife pare off the projecting veins, so that there will be as little roughness as possible, then place them in books, with a heavy weight, and press them smoothly, leaving them there until you are ready to use them. Prepare the article by painting it black, using a fine brush for the purpose, because it will leave fewer traces. When this is perfectly dry and hard, give it a coat of fine transparent varnish, and before it has become entirely dry, lay on the leaves and fern sprays in graceful groups, according to fancy, pressing them smoothly down, so that every part will adhere. When they are entirely dry, give it another coat of the same transparent varnish, going over the whole surface, leaves and all. If you wish to bronze the black ground in imitation of the Japanese lacquer ware, it can be done by sprinkling a little bronze powder over the sticky varnish after putting on the leaves, then rubbing it lightly with a soft rag to burnish it. These ornamentations are both permanent and effective.—*Cabinet Maker.*

Among the few inventors who have had the satisfaction of beholding the universal acceptance and commercial success of the offspring of their genius must be mentioned M. Jean Engelmann who died a few days ago in Paris. The problem of printing in colors was solved by him, and, indeed, the improvements he introduced in various branches of lithography justify the remark of a French journal, that the whole history of the progress of this art in France is summed up in his name. Beside the important invention of chromo lithography, the modification of this process known as *diaphanie*, and applicable to the decoration of glass, is due to the initiative of M. Engelmann. This eminent lithographer also devoted much of his time and energy to the reproduction of archæological works.

Cause of Hunger.

Persons Eating When Not Hungry.

The feeling of hunger is not caused by the emptiness of the stomach, but the stimulus of the gastric juice which is continually being secreted when in a state of health. Sometimes this secretion stops for reason of the various kinds of derangement in health; then no food can be digested; and there is no feeling of hunger, notwithstanding the stomach may be empty. Of course when in such a condition, it is very injurious to eat, and a horse or any other animal will not do it; but, unfortunately, most men, when the time for their meals has arrived, think that they must eat, hungry or not. The food is then introduced into a stomach unfit to digest; remains undigested, putrifies, and no end of troubles is the consequence. Some persons think they may stimulate their appetite by a tonic, such as bitters or other vaunted preparations; but this is a mistaken course, for its only result is to cause one to eat more when already an amount has been consumed beyond what the gastric juice has been able to prepare. The object to be attained is a large supply of gastric juice, not a large supply of food; and whatever fails to accomplish that object, fails to have efficiency towards the cure of dyspeptic diseases. The formation of gastric juice is directly proportioned to the wear and tear of the system, which it is to be the means of supplying, and this wear and tear can only take place as the result of action. The efficient remedy for dyspepsia is exercise—out-door exercise—beneficial and successful in direct proportion as it is agreeable and interesting.

A still more prolific cause of dyspepsia is drinking; and the danger of excess in this instance is still greater than in the case of eating, as drinks go down more easily than meats. The strongest proof of the excess daily committed by mankind in this direction is the fact that no trades are more flourishing than those dealing in things which people can get down their throats; and the manufacture and sale of drinks, as they go down the easiest, is the most prospering of all, especially beers and wines, and even the two extremes, soda water and whisky.

Every one knows that it is impossible to make a horse drink when he is not thirsty; and also that nothing is easier than to make an ordinary man take a drink whether he may be thirsty or not; and this is what makes the drinking saloons flourish, and keeps so many drunkards' households down in poverty, in case the head of the family has not manliness enough to resist the temptation of *"taking another drink."—Household Magazine.*

Preserving Cider.—A barrel of cider may be preserved in good flavor and condition for next spring by the following method: Fill a clean, strong barrel with juice from sound, good apples, and let it ferment from two to three weeks, until the liquor becomes quite clear. Then rack the cider into tubs, cleanse the barrel and fill it with the fumes of burnt sulphur by burning a rag, dipped in melted brimstone, in the barrel. Replace the cider in the barrel, taking care to fill the cask full, and bung tight. If kept in a cool cellar, it will be nice next April and May.

Good Health.

Feeding Babies With Starch.

The dangers liable to arise from feeding babies upon corn starch is set forth by the London *Sanitary Record* as follows:

Dr. W. Domett Stone writes to a contemporary, stating that his attention has been called to a report of a trial at Taunton, recently, of a married woman, on a charge of starving her twin children to death by feeding them on what is called "corn flour," which she had been warned by her medical man was incapable of sustaining life. Death in both instances having clearly resulted from partaking of this preparation, it cannot, he contends, be too widely known that "corn flour" *per se* is not food, but pure starch, prepared by washing out of maize flour the nutritive portion with alkalies, as was abundantly proved by the evidence of Dr. Bartlett before the Adulteration Committee of the House of Commons last autumn.

Numerous instances of children reduced to skin and bone, from being fed on one or the other of the "corn flours" now before the public, have come under his notice. It may be of some use to your readers to have a "rough-and-ready" test to distinguish those farinaceous foods which are innutritious. Whenever the powder is beautifully white and of extreme fineness the article should be rejected, as being almost certainly composed of starch alone. When, however, the nutrition has not been sacrificed to appearance, and they present their natural brownish color, some of these foods may contain even more nourishment than meat.

Disinfectants.—After an exhaustive series of practical tests of the various disinfectants sold in New York, embracing over fifty kinds, Professor Elwin Waller, of Columbia college, concludes that the best disinfectant is carbolic acid. About one per cent. of the mixture should consist of carbolic acid. For prompt disinfection which is only temporary, strong oxydizing agents, as chlorine, potash permanganate, nitric acid, etc., should be used. Of these the cheapest and most available is chloride of lime.

Extraordinary Sea Sickness.

The following experience of Captain R. C. Coleman, of the American rifle team, was obtained from a member of his family, and of course is authentic:

The Captain, soon after getting out of sight of land, was attacked with a peculiar kind of sea sickness which is very rare, it affecting not more than one in a hundred passengers. Instead of developing in the ordinary form of terrible nausea, it affects the brain, producing delirium and all the symptoms of brain fever. If the patient remains in this condition until he reaches land, or even feels a land breeze, he may recover, but a recovery from this disease under other circumstances than those mentioned—that is, while on board the ship away from land—is sure to be followed by ship fever, which is certain and almost immediate death. The fever and delirium lasted during the entire passage over, and his comrades were almost certain that he would be too much unstrung to shoot in the team. He recovered rapidly, however, on reaching land, and his practice soon proved that his ability to hit the bull's eye was not impaired.

The Captain was informed by the ship physician and other high medical authorities that he had a narrow escape from death, and that he ought not to cross the ocean again. Under such circumstances he very naturally dreaded the return voyage, but it had to be attempted at any rate. Soon after starting on his return he was attacked the same as before, though even more severely. He remained delirious the whole time, however, until the vessel reached Sandy Hook, and escaped ship fever. It was a severe experience; but considering the fact that few affected as he was survive a second ocean passage, he feels that he was very fortunate. Though he returns covered with honors, it would take greater inducements than the victories of Dollymount or Wimbledon to tempt him to cross old ocean again.—*Middletown (Conn.) Press.*

Alarming Spread of Trichinosis.

The *Transactions* of the Indiana State medical society, 1875, contain a report on trichinosis, by Dr. George Sutton, of Aurora, Ind., which contains the following alarming observations:

From microscopic examination of pork killed in Southeastern Indiana, we have found from three to sixteen per cent. of the hogs affected with trichina, the number of hogs diseased varying greatly in different localities.

That over five millions of hogs are slaughtered and packed in the Western States, not including those which are put up for family use by the farmers; that if four per cent. of this pork is diseased, which we believe to be a low estimate, we have 221,484 diseased hogs put annually upon the market; or over 4,000,000 pounds of diseased meat, every ounce of which, under favorable circumstances, is capable of producing disease.

That from the cases of trichinosis that came under our observation, and the *post mortem* examinations, and the effects upon the dog that was fed on the diseased meat, we have come to the conclusion that ninety per cent. of disease produced from eating trichinous pork appears either as gastro-entiritis, or as a diarrhœa or dysentery, and not more than ten per cent. as the fully developed form of trichinosis, in which the muscular system becomes affected.

That as diarrhœa, dysentery and enteritis rank high as causes of mortality in the United States, these diseases causing 31,153 deaths in 1870, as shown by the last census reports; and as we have seen that a large amount of trichinous pork, capable of producing these diseases, is among the principal articles of food in our country; we think it more than probable that trichinæ have a much greater influence in the causes of this class of diseases than has been recognized by the profession.

That it is highly probable that, when the fact becomes more generally known that so large a percentage of pork is swarming with trichinæ, capable of producing disease, it may have an effect upon the use of this meat, and consequently affect the sale, to some extent, of one of the principal articles of commerce in the West.

Oxygen as a Medical Application.—Soon after the discovery of oxygen gas, a strong feeling arose in favor of its medicinal application. Various diseases, such as scurvy, were ascribed to a deficiency of it in the system, and it was accordingly employed in many cases, and, as was at first declared, with brilliant results. In England, it was tried by Beddoes and Hill. The latter declares that he found it useful in asthma, weakness, ulcers, gangrene, white swellings, and scrofulous affections of the bones. These views have been again abandoned, both on chemical and physiological grounds. In asphyxia, from want of air, or from the inspiration of pernicious gases, oxygen gas may be inhaled with advantage. For the same reason, it has been recommended in spasmodic asthma, attended with danger of suffocation. Still it is, at the best, a mere palliative, and can by no means prevent renewed attacks. If we consider, in the application of oxygen gas, its physical action, as already discussed, we shall readily conclude that the inspiration of oxygen is in most cases useless, and that but little—and only in few cases—can be expected from its therapeutical application.

Domestic Economy.

Devonshire Cream.

This is considered a great luxury in the "old country." In Devonshire it is found in every market place, and is sold at about the same price per pound as butter, which costs more time and labor to produce. It is more perishable than butter, but less than cream that has not been cooked. Of course, the fresher it is the better, though it retains its eatable qualities for several days if properly cared for. If it were once fairly introduced to the American public by confectioners and dairymen, there is no doubt that a brisk demand for it would follow.

Directions: New milk fresh from the cow (Alderney or Jersey is best, because richest) is strained into a shallow pan and set away over night, or if in the morning, for the day, to allow all the cream to rise. This pan of milk, with the cream undisturbed, is then placed over the fire in another pan partly filled with water, and allowed to heat gradually until the milk is almost ready to simmer, when it is removed from the fire and set away for several hours to cool. When quite cold, the cream, which by the cooking has become thick and stiff, is skimmed off from the milk, and is then ready to be eaten. It is a nice point to know just when the milk is sufficiently heated, for if it is permitted to "come to a boil," it is spoiled for true "Devonshire," as the cream is set once dispersed and mingled with the milk, and the whole is no better than boiled milk and scum. By watching the surface, however, a careful eye will, at the right moment, see the cream begin to rise a little in the center; the pan should be immediately removed, before the surface becomes broken. It is usually served at dessert with berries or stewed fruits. Great caution must be used not to ruin the cream by over-cooking, but it is almost as nice a point for people with delicate stomachs to know just when to stop eating it.

A Good Family Soup.—According to the London *Agricultural Gazette*, a very good family soup is made from one and a half pounds of lean beef, two pounds of potatoes sliced thin, one large carrot, one large onion, a few shalots, one turnip, one stick of celery, four quarts of water. Let it simmer four hours, flavor with hot sauce to suit the taste, salt, pepper, etc. It is a great improvement to fry all the vegetables when cut in small pieces, together with the meat also cut in pieces conveniently small, taking care that there is fat enough added to prevent the raw vegetables from burning. A dessert-spoonful of coarse brown sugar may be thrown into the pan while the meat, vegetables, etc., are frying. After it has simmered four hours, it should be set to cool for the fat to be taken from the top of the soup before being served up for use. The meat should be sent to table in the soup, not strained as is usually done.

How to Bake an Apple Pie.—Pie is generally denounced, and with justice. The crust is either too rich, or tough and heavy, unfit for digestion, and unpalatable. Yet there are those who come to the rescue of this much abused piece of American cookery. But this is a different article altogether. It is a nice and yet a simple thing to make a pie that is both relished and healthy—that lies light on the stomach, and is easily digested. In this case it becomes a tidbit, and at the same time is inexpensive. Take half a teacupful of butter to a pie of ordinary size, to be rubbed in well with the flour, about a pint. Make into dough after adding sufficient water and a little salt. Quarter the fruit and lay close together; season to suit. In the case of the Spitzenberg no flavoring is required. Have the crust rather thin. Bake slowly and have it well done.—*Household Magazine.*

Rock Cream.—Wash a teacupful of the best rice, and boil slowly until quite soft, in new milk; add white sugar to taste, and then pile it on a dish. Lay on in different places lumps of jelly or thick preserved fruit. Beat the whites of five eggs to a stiff froth, with a little sugaring and flavoring. When well beaten add a tablespoonful of rich cream, and drop it over the rice, imitating the form of a rock of snow. —*Exchange.*

Cucumber Catsup.—The following is an English recipe: Gather the cucumbers when full grown, but before they turn yellow; peel and grate them; let the pulp remain upon a colander until the juice drains off; then rub through a coarse sieve, to separate the seeds; half fill bottles with this pulp, fill up with vinegar, and keep well corked. This retains, in a marked degree, the odor and taste of fresh cucumbers, and is excellent with cold meats. When served at table, salt and pepper are added.

Insipid Food.—Insipid food is not wholesome; and, on the other hand, food with too much taste over-stimulates the appetite and causes over eating. So, too, many foods not in themselves insipid, are made to appear so from contrast after one has been a long time accustomed to highly seasoned food.

MINING AND SCIENTIFIC PRESS.

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, W. B. EWER, GEO. H. STRONG JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week.	1 month.	3 months.	1 year.
Per line..... .25	.80	$2.00	$6.00
One-half inch.....$1.00	3.00	7.50	24.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the PRESS promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so?

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

San Francisco:

Saturday Morning, Oct 30, 1875

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Henderson Hydraulic Car Brake; Improved Hydraulic Nozzle; The Wholesale Clothing Trade, 273. The Virginia Disaster; The Reduction and Refining Works of R. J. Kohler & Co., 280. Our Home Industries; The Eureka Mine; New Single Track Railway; A Steam Fire Launch for San Francisco; The Divining Rod, 281. The Concentrating Works at Falun in Sweden; Patents and Inventions, 284.

ILLUSTRATIONS.—The Henderson Hydraulic Car Brake; Little Giant Nozzle, with Improved Lever and Crank Attachment, 273. C. H. Townsend's Improved Kitchen Table, 278. Design for a Steam Fire Launch for San Francisco Harbor, 281.

CORRESPONDENCE.—What Constitutes a "Mineral Vein" Within the Meaning of the Law, 274. Sulphurets, 284.

MECHANICAL PROGRESS.—Heating Feed Water for Steam Boilers; Frameless Houses; To Drill into Hard Steel; Burning Coal Dust; A New Hot Air Engine; New System of Plastering; Street Car Motors; Belting in England; How to Calculate Centrifugal Force; An Electrical Engine; Berlin Iron, 275.

SCIENTIFIC PROGRESS.—A New Mode of Measuring the Intensity of Light; Arctic Geology; Coloring of Birds' Eggs; Webb's Famous Swim Scientifically Considered; The Acid of the Gastric Juice; Counting the Blood Corpuscles; The Oil Diagometer; The New Fossil Bird; The Progress of Science, 275.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 276.

MINING SUMMARY from various counties in California, Nevada and Idaho, 276-7.

USEFUL INFORMATION.—Effect of Magnetism on Watches; Common Sense Ventilation; Ornamentation with Autumn Leaves; Cause of Hunger; Preserving Cider, 279.

GOOD HEALTH.—Feeding Babies with Starch; Disinfectants; Extraordinary Sea Sickness; Alarming Spread of Trichinosis; Oxygen as a Medical Application, 279.

DOMESTIC ECONOMY.—Devonshire Cream; A Good Family Soup; How to Bake an Apple Pie; Rock Cream; Cucumber Catsup; Insipid Food, 279.

MISCELLANEOUS.—Shall We Ever Travel Faster? On the Vitality of Certain Land Mollusks; The Generation and Characteristics of Smoke; The Eureka and Palisade Railroad; The Cry for Capital; For Carpenters, 274. Government Tests of Beams, Girders and Columns; Mussels on the Great Eastern's Bottom; A Handy Kitchen Table; Around the World in Eighty-eight Days; Brimstone Works; The Microscopical Society; Humboldt District. Calaveras County Quartz Mines; Manufacture of Paper; Rich Strike in the Fourth of July; Big Teams, 278.

THE RAINFALL.—Our dry season may now be considered over, as the first shower of rain fell on Tuesday night. On Thursday morning, also, a slight shower fell. Tuesday's rain amounted to .18 inches, and that of Thursday to .04 inches, or .22 inches in all.

THE pump trial has not yet come off, owing to the fact that the competitors have not yet completed all their arrangements. They are all busy, however, and in a few days at farthest this interesting trial will take place.

THE water in the Carson river is steadily on the increase and it will not now be long before the mills can greatly increase the amount of their crushing.

WORKMEN are now framing the timbers for the railroad bridge to span the Pajaro river. The structure will be 300 feet long, with a pier in the center.

IT is expected that the rich ore vein developed in the Justice mine will run directly into the New York Consolidated.

QUICKSILVER is so low and business in consequence so dull at Calistoga that the *Free Press* has issued its valedictory.

The Virginia Disaster.

Most unwelcome news came to this city on Tuesday morning, that Virginia, Nevada, was in flames and that not only the main business portion of the city was being destroyed, but several extensive mills and hoisting works also. This news proved to be too true, and now that the main details have come to hand we find that, contrary to the usual custom, the fire was as destructive as represented. Since the failure of the Bank of California and the sensational occurrences following, there has been nothing like the excitement which prevailed in San Francisco. The two cities are so closely joined by business interests that the calamity in one seriously effects the other.

The fire broke out in a small house on A street, between Taylor and Union, and spread until it burnt up the larger and more substantial portion of the town. From Stewart street to H, and from south of the Bank of California, almost to the divide beyond the Ophir, the city is a ruin. The burnt district extends over an area of three-quarters of a mile in length by half a mile in width. The loss is at present difficult to compute. A strong wind was prevailing at the time, and all efforts to prevent the spread of the fire proved unavailing. The flames and burning cinders were carried hundreds of feet, setting fire to buildings in all directions. Hardly anything was saved in the burnt district, and it is stated that 10,000 people are homeless on the hills, thankful that they escaped with their lives. Only one man was killed, and he by a falling wall.

Within the devastated district were many of the finest business houses and residences. Among the buildings destroyed we mention, besides the mining works, the Catholic, Presbyterian and Episcopal churches, the two printing offices, the railroad depot, the Bank of California, the International Hotel, Williams' block, the Post Office, Pioneer Hall, Piper's Opera House, Washoe Club, Mary's building, the Tahoe House, stores, livery stables, offices, residences, shanties, etc. A number of the best residences in the city escaped, and there is a considerable section of the city left despite the calamity. All the business houses carried heavy stocks of goods, having laid in their fall and winter lines. A brisk trade was anticipated after November 1st, when it was believed that a large number of miners would be paid off, and all were preparing for a lively winter trade. The conflagration has in many cases caused all these hopes to be abandoned. Not only have the stocks of merchandise been destroyed, but the buildings containing them have been swept away. As soon as the confusion and chaos occasioned by the calamity have been somewhat allayed, arrangements will be made to erect temporary buildings, and, if possible, to construct substantial stores on the sites of those destroyed, though some of those burned down were considered fire-proof. The merchants of this city will extend all possible facilities to their customers to aid them in resuming business, and give to those who need it a new start.

The losses to the mining companies are very serious indeed, as the works destroyed were of the most substantial and expensive character. The Consolidated Virginia hoisting works, building and sixty-stamp mill, the battery department of the new California mill, the Ophir works and all the surroundings were destroyed. The Gould & Curry and Andes works had a close shave of it, but were saved. It was hoped to save the Ophir, and giant powder was freely used, but with no avail. When it was observed that the works of the Ophir were in danger, orders were given to bulkhead the shaft at a point about twenty-five feet from the surface, where a tunnel extends to the surface of the ground, about two hundred yards to the eastward. This tunnel has been constructed with a view to such catastrophes as that of yesterday, so that men might escape below it and the shaft be bulkheaded at the point of its intersection. A strong platform was thrown across the shaft, and so much earth piled on as to make it almost fireproof. This work had been accomplished just as the flames had enwrapped the building, and all hands had to flee for their lives. The shaft, from the fireproof partition to the surface and the whole length of the tunnel, were exposed to the fire, but the mine below Mr. Curtis considers secure. Mr. Curtis says that as soon as possible he will have men at work constructing a covering for the shaft and machinery, and commence retimbering down to the level of the tunnel as soon as timbers can be had. All the timbers in the yards have been burnt. The boilers and all the larger portions of the engines are in such a condition that they will do for work again. The boilers are all in place, and partly filled with water, and as soon as possible an engine will be put in position to lower and hoist into the mine. The Ophir workings are so far beneath the surface that an engine larger than a portable donkey will be required. Mr. Curtis has no fears for the safety of the lower workings, and says that even in the event of the possible burning of the shaft below the bulkhead the ground would not cave.

The shaft of the Consolidated Virginia mine was bulkheaded a few feet from the surface by lowering safety cages, springing the catches and piling dirt or ore upon them, thus saving the shaft. On Tuesday night, as smoke was seen issuing through the shaft openings on the bulkhead, it was thought to come from the Ophir. It was also thought there might be fire underground, as there was so much gas rising from the Gould & Curry, that the men could not go into the shaft. A dispatch sent down to-day (Thursday) at 10:40 A. M., states that men have been through the Consolidated Virginia mine as far north as the Ophir line, and everything was all right. The gas in the Gould & Curry came from the old shaft in the Sides ground. This dispatch states that it is certain the Ophir shaft is not badly damaged and is not on fire.

The Consolidated Virginia works will be immediately rebuilt, as will all the others destroyed. Those of the Consolidated Virginia were new and extensive. The Lady Washington mine has duplicates of the machinery, and it is thought they will be purchased for the bonanza mine. The heavy parts of the machinery are not much injured, but the full damages are not yet ascertained. A new flume to the Sierra Nevada mountains will be constructed at once in order to get mining timbers as soon as possible. The saw mills are already running on foundation timbers for the Consolidated Virginia, and they are cleaning off and pushing work as fast as possible. The California mill was entirely new, just completed and was never run a day. It was the finest over built on this coast, the machinery being heavier and more extensive. The pan department of the mill was saved, being some distance from the battery. The surface machinery of the Consolidated Virginia was also of the most substantial and extensive kind and perfectly new. The Ophir works were also of great value, but will soon be replaced.

The Consolidated Virginia mine was the only one upon the Comstock lode that was paying dividends, disbursing over one million dollars monthly since last March, with every prospect of increasing this amount in a few months had not this calamity befallen it. The greatest loss is not that sustained by the burning of the buildings, but the stoppage of work in the mines dependent upon the Ophir shaft, and either the cessation or diminution in amount monthly of dividends from the Consolidated Virginia for several months.

The Con. Virginia hoisting works are entirely destroyed, but this need not prevent the extraction of ore, as it is connected with the Gould & Curry by two drifts, one connection being at the 1145-foot station and the other at the 1500, the latter being the drift that will most probably be used to run this ore through the Best & Belcher to the Gould & Curry shaft, the hoisting power being fully sufficient to raise from 500 to 750 tons of ore daily, besides running the pumps.

The destruction of the Consolidated Virginia mill, and also the batteries of the California, entail no loss upon these companies, as they belong to the Nevada mill and mining company—a corporation of which the principal stockholders are J. G. Fair, J. C. Flood, Wm. S. O'Brien and John Mackay. These mills were named after those mines, and were erected principally to crush the rock extracted from them. The loss of the use to the California of these batteries, or stamps, is especially severe, as these works had just been completed and would have started up crushing its rock sometime in November. Nearly a year was occupied in building the foundations and putting up its machinery, while its sixty stamps were intended to crush 250 tons of ore daily. But the lack of these mining facilities will no doubt be soon remedied by the employment of some of those mills which were lying idle this summer upon the banks of the Carson river for the want of water to run them, and which at this season of the year increases in quantity by the fall rise and the rains which are near at hand.

The rebuilding of the destroyed works will not take so long as their first erection, especially the machinery, patterns of them being saved at the machine works in this city, who can cast and finish their duplicates at very short notice. The shafts are uninjured, with the exception of Ophir, whose top of shaft caught fire, with the extent of the damage not yet ascertained. The Con. Virginia was saved by the covering of its shaft with iron doors and overlaying these with bags of sand, which prove sure securities against the entrance of fire to the interior of shafts.

As yet the full extent of damage is not known. Collections are being made all over this State and Nevada in aid of the sufferers. Wells, Fargo & Co., as usual, are in the van in this good work, collecting and forwarding supplies and money free of charge. The San Francisco Stock Board sent $6,000; Wells, Fargo & Co., $1,000; the Pacific Stock Exchange, $2,000, and many individual contributions swell the amount. Bales of blankets, packages of provisions, and quantities of supplies are being sent forward. Virginia has been very unlucky of late. The day before the fire an immense body of water flooded several mines; for several weeks typhoid fever has raged there, and now fire destroys the city and the works of two principal mines. It is expected the losses will foot up to four or five millions of dollars, and it will take many a day to repair the damage. The people of Nevada, however, are energetic and plucky, and already steps are being taken to rebuild and repair as far as possible.

Our cotemporaries, the Virginia *Enterprise* and Virginia *Chronicle*, whose offices, type, presses and material were entirely destroyed, will, no doubt, resume again shortly. Their proprietors have the sincere sympathy of their brethren of the press. The insurance men have sent their adjusters to the scene of disaster and by our next issue some definite idea may be had of the aggregate loss. The machinery destroyed will be immediately replaced, and as the patterns, etc., are all at the foundries here, it will probably take not more than ninety days to replace the whole machinery. The mines which have lost their works are amply able to pay the loss without assessment, but the big bonanza mine may have to pass its assessment this month. The mines will hardly have to shut down for any length of time, but the disaster unhappily throws a great many men out of employment at an inclement season of the year. A more serious blow to the business interests of this coast could not have occurred, and coming, as it does, on the heels of a heavy financial panic, it will of course work injury to hundreds who were not directly interested in the town. We will be able to give full details of losses and damage next week. The effect of the fire on the mining share market is commented on in another column.

The Reduction and Refining Works of R. J. Kohler & Co.

[Written for the PRESS by E. PIQUE.]

MESSRS. EDITORS:—Having had the opportunity of visiting the above works, I wish to give you a short description of them, as it might be interesting to some of your readers. These works are erected about six miles from Oakland, and are connected on one side with the Central Pacific railroad, and on the other with the bay, so as to insure an easy transportation of ores and materials by water and by land. Their object being to extract the precious metals from any kind of ore, no matter how rebellious and in whatever combination with base metals and other substances, their apparatus is adapted to a variety of operations, such as smelting, refining, roasting, lixiviating, etc. The works are on a very large and substantial scale, involving the expenditure of a very large capital, insuring durability and saving later expenses for repairs and loss of time, connected with other works of a cheap and slight structure. When in complete working order, they will be able to reduce fifty tons of ore per day. Their chimney will be 125 feet high, when finished; at present it reaches seventy-five feet, which is sufficient to commence operations. The smelting furnaces consist, at the lower part of their circumference, of a strong, double wall of cast iron, and between these two walls a regulated stream of water is circulating, so as to prevent the iron walls from being destroyed by too great a heat. The upper part of the smelting furnaces is made of fire-bricks, and the escaping fumes of lead, antimony, arsenic and other volatile substances are forced to travel a long way before they reach the chimney, and to deposit in those underground chambers, and partly at the bottom of the high chimney, everything valuable that would otherwise be carried out in the open air and lost. The refining furnaces are built on the most approved principles, and furnished with some of Mr. Kohler's own improvements. The roasting furnace is a long one, so that three lots of ore can be roasted at the same time, being exposed gradually to different degrees of heat, as understood by metallurgists. This furnace, like everything else, is very substantial, and provided with a very large number of strong iron bars, braces and screws, so as to steady the brick-work.

For the different mechanical operations there is a steam engine of sixty-horse power, besides an excellent artesian well, yielding water in great abundance, and a great many other contrivances, too numerous to mention. A particular feature is a set of apparatus, invented and patented by Mr. Kohler. I am not permitted to enter into details, but I am confident that the very powerful chemical action produced by the above contrivance, will enable Mr. K. to extract completely the precious metals from a certain class of rich ores that would give up only a very small portion of their treasures by any other treatment. Mr. K. being himself the proprietor of a very valuable mine, and having also the promise of very large amounts of ores from other extensive mines, to be worked by him, I do not doubt in the least that the enterprise will be a complete success, rewarding Mr. K. and the shareholders interested in it, according to their highest expectations.

ON THE WRONG SIDE.—The Gold Hill *News* in speaking of the Ophir mine says that it is now confidently believed that the greater proportion of the work done in the mine during the past three or four years has been on the west side of a great horse of porphyry, and that the east side of the ore vein has never been reached at all.

THE Alameda *Independent* is our authority for saying that work on the narrow guage road is going on actively. Three miles are ready for the ties. This portion is on the high ground near Newark, extending southerly from the marsh ground between that place and Dumbarton point. In three weeks it is expected to have the embankment for the road to the marsh.

MR. CARTER, of the firm of Carter Brothers, San Francisco, car builders, is now at work putting up the turn-table at the Grass Valley depot.

IT is intimated that the Southern Pacific will be completed from Soledad to San Miguel within the next eighteen months.

Our Home Industries.

Manufacture and Preparation of Chocolate, Etc.

In reviewing the industrial interests of the city of San Francisco, noting at the same time some of the establishments which figure most prominently therein, we have at different periods and on many occasions spoken at length of the value and importance which the multitudinous industries bear upon the mercantile transactions of the State, and also the acknowledged high reputation which our houses have achieved abroad, in such localities as Mexico, Sandwich islands, Japan, China, etc., the manufactured goods of the city finding a natural channel in the transactions or business intercourse with foreign as well as home countries.

The number of business institutions or diversified branches of general trade which forms the basis for commercial transactions in all the important cities of the United States, is immense. Was it possible to enumerate or give in detail the character and importance of each business house, a number of copious volumes would be necessary. What we would most directly speak of here is the manufacture and preparation of chocolate.

In this direction our city is not inferior in the quality of production, although in quantity it may be equaled or even surpassed by the older cities of the Eastern States. An establishment for the manufacture of chocolate was instituted in this city as early as 1852, and since that period the progressive strides of manufacture have become apparent on every hand, the establishment under discussion becoming identified with the progress, and increasing palpably every year. Mr. D. Ghirardelli formerly carried on the manufacture of chocolate in Peru, and at the period above named he settled in this city, the opportunity here for a wide field affording him auspices for successful prosecution.

The Eureka Mine.

The Eureka (Grass Valley) mine is one of the well-known gold mines of California. The company went into operation about the 1st of October, 1865, since which time it has turned out $4,373,239.85 in bullion, from which dividends to the amount of $2,054,000 have been paid. The dividends have amounted to $102 70 per share. The past year, however, has not been a favorable one, and an immense amount of prospecting has been done, and a large amount of money expended without making any favorable developments. In the annual report, however, the superintendent states that there are still three places worthy of a further prospect, viz.: the 12th level, the Roannaise from No. 3 shaft, and the Morehouse claim.

The mill, hoisting and pumping machinery although getting old, are still in fair working order.

Referring to the Morehouse claim, the president explains to the stockholders that the claim is located south of and cuts the Eureka ledge at right angles, comprises 1,800 feet in length and is covered by a United States patent which includes twelve acres of surface ground. The explorations in the Eureka seem to indicate a probability of the ledge having turned south across Wolf creek into the Morehouse ground instead of continuing west, through the Roannaise ground. For these reasons the trustees of the Eureka thought it advisable to secure the Morehouse claim, the owners of which having fixed a higher value on it than they were willing to pay, an arrangement was made with them as follows: When the Eureka company shall have expended $10,000 in prospecting their ledge, the Morehouse company will deed to the Eureka one-half of the claim. It is further agreed that the Eureka company have the right to stop work at any time they wish to do so, and to remove any machinery they may have on the claim. Shaft No. 3, referred to above, is on the Roannaise ground further to the east than any previous prospecting.

During the year ending September 30th, 1875, in the Eureka mine proper they drove 196 feet of drifts, 879 feet of cross-cuts, and sunk 34 feet of winze; they also sunk 71 feet of shaft on the Roannaise, and 22 feet of shaft and drove 611 feet of drifts on the Eureka No. 2. They hoisted 4,235 tons of quartz and crushed 4,310 tons in 214 running days, with 10 stamps, averaging a little over two tons per day to each stamp. They also concentrated 27¼ tons of sulphurets and worked 39⅛ tons, having also on hands 4¼ tons. There are 250 tons of quartz on the surface, 100 broke in the mine, and Mr. Wm. Watt, the superintendent, estimates there are upwards of 900 tons of ore in sight, which will pay a small profit. The majority of the quartz taken out last year came from the 6th level of the Eureka—3,402 tons out of the 4,235 hoisted.

From the secretary's report for the year ending September 30th, 1875, we make the following extracts, showing the financial affairs of the mine:

RECEIPTS.

Book Account, Oct. 1, 1874	$ 98,340.36
Bullion Account	100,091.36
Mine Account	21.00
Mill Account	725.10
Wood Ranch	100.37
Wood Account	12,897.56
Premiums	446.55
McDougal Works	450.56
Interest	5,700 00
Total	$218,572.91

DISBURSEMENTS.

Mine Account	$ 39,340.26
Mine Account, Prospecting	43,667.50
Mill Account	15 213.56
Sulphuret Concentration	1,042.00
Sulphuret Reduction	243.00
Mine Purchase	800.00
Eureka No. 3 Shaft	2,840.47
Eureka No. 2 Mine	18,476.51
Wood Account	13,083 41
Wood Ranch	88.75
McDougal Works	240.00
Bullion Expenses	388.15
General Expenses	6,163.74
Discount Account	1.96
Book Accounts, Sept. 30, 1875	76,974.57
Total	$218,572.91

The largest item in the receipts was from ores worked—$97,801.91. The heaviest item in the disbursements was for labor on mining account. The pay rolls amounted to $50,725, and the labor on contract was $10,908.

The assets of the company are placed at $120,316 and the liabilities nothing.

They hoisted 4,235 tons of ore during the year and crushed 4,310 tons at the company's mill.

On October 1st, 1874, they had on hand 16½ tons of sulphurets and concentrated during the year 27¼ tons, making 43¾ tons. They worked 9 tons during the year and sold 30⅛ tons. The 27¼ tons concentrated during the year cost on an average of $38.24 per ton. Those worked yielded $91.36 per ton and those sold $47.39 per ton. The 9 tons worked yielded $822.23 and the 30⅛ tons sold yielded $1,415.50.

They worked 4,310 tons of ore by mill process, which yielded $97,823 62. All the ore worked, including sulphurets, yielded an average of $23.21 per ton.

As reduced by mill process the average fineness of the bullion was .844⅛, equal to $17.45 92-100 per ounce. As reduced by chlorination process the average fineness was .985½, equal to $20,37½ per ounce.

The cost of mining 3,985 tons was $39,628.26, or an average of $9.94 per ton. The cost of milling 4,310 tons was $14,388.41, or an average of $3 34 per ton.

Since going into operation, in 1865, the company has disbursed for purchase of mines and perfecting titles, $302,706; for construction, $158,383; for dividends to stockholders, $2,054,000; for mining, milling and other expenses, $1,819,940; making a total of $4,335,030. The receipts from bullion from the mine in this time have been $4,373,239. The net profits have been $2,595,057.

New Single Track Railway.

W. H. Harrison, of Livermore, Alameda county, has recently invented, and patented through the Mining and Scientific Press Patent Agency, an improved single track railway. The improvement consists in a novel means of guiding and steadying the carriage upon its single line of wheels, by means of a series of rollers or pulleys which are fixed upon each side of the rail, while the carriage is provided with a rail upon each side, which successively engages with the pulleys as the carriage passes, and thus maintains it in a proper position.

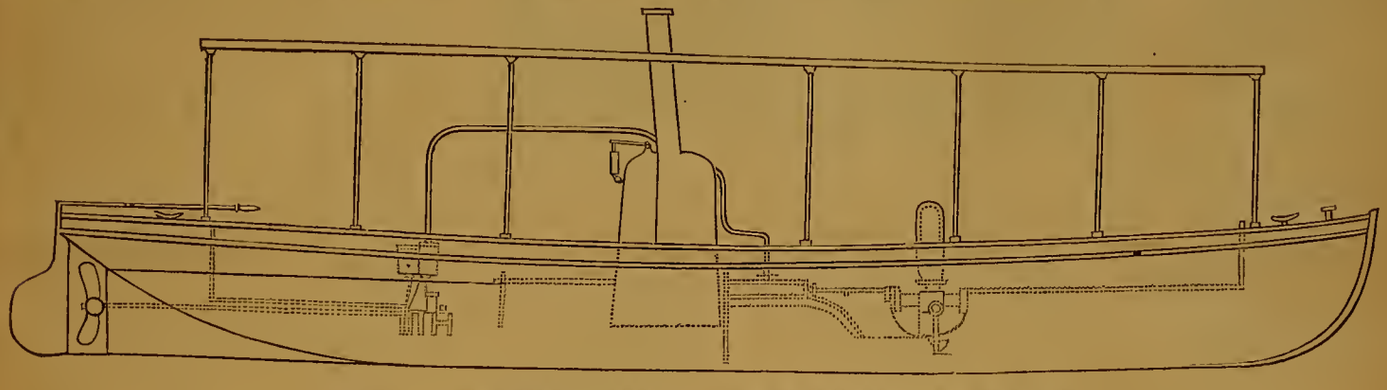
The carriage is mounted on suitable bearing wheels, which are fitted to run upon the single rail. In order to give the carriage stability it will be necessary to guide it at times, although when running at a high speed upon a perfectly straight line, it will be nearly self-sustaining (like a hoop), and will only be thrown off its balance by imperfections in the work. Mr. Harrison's guiding device consists of a rail at each side which is strongly secured to the car in any suitable manner, so that the pair of rails stand opposite each other beneath the level of the car body.

At intervals, upon each side of the main rail, pulleys are fixed so as to turn upon vertical axes, and these pulleys are so grooved that they receive the edges of the rails as they pass, and thus maintain the car in a perfectly horizontal position. The pulleys may be secured in pairs to strong metallic base plates, or any other desirable method may be employed. The ends of the guiding rails are slightly beveled, so as to insure their taking the pulleys easily and without shock. The arrangement is quite simple and easily carried out.

A Steam Fire Launch for San Francisco.

The floating fire engine, of which we give an illustration, is designed for the protection from fire of the shipping wharves and property adjoining the water front. It consists of a steam launch fitted with fire-engine. The length of the hull is thirty-five feet; beam, seven feet. The engine for propelling this little craft is placed near the stern, as will be seen, and is quite independent of the fire-engine, although but one boiler supplies both with steam. The speed is eight miles an hour. To avoid, if possible, the use of salt water in the boiler, fresh water tanks are fitted sufficient for a supply of about one hour's steaming. An awning for the protection of the machinery when stationary is provided, extending, as will be seen, from end to end. It is of wood and made in three sections, so arranged that the whole or part can be easily removed. The fire-engine is placed in the forward end of the craft, working horizontally. The diameter of the steam cylinder is 6½ inches; stroke, 18 inches; and the pump 5¼ inches diameter by 18 inches stroke, capable of discharging 300 gallons per minute to a hight of 160 feet. The delivery is provided with two branches, but if desired, four may be used, in which case four jets, five-eighths of an inch in diameter, could be thrown simultaneously to a distance of from seventy to eighty feet. The suction is taken from the boat's side through a perforated plate.

The boiler is on the Field principle, which is doubtless well known to our readers, in which steam can be raised from cold water in ten minutes. A successful trial of a similar floating engine was made in the East not long since, and from the great ease with which the craft was handled, and rapidity with which she steamed from place to place and at once got to work, we have no doubt that this floating fire-



DESIGN FOR A STEAM FIRE LAUNCH FOR SAN FRANCISCO HARBOR.

The establishment, Nos. 415 and 417 Jackson street, this city, a property forty-six by eighty feet, three floors and basement, contains machinery particularly adapted to the manufacture, and having been constructed in Paris, France, and shipped especially for use in the establishment of which we speak. To this reason we can assign the superiority of the manufacture of this house. Our manufacturers can not only excel the French in the quality of production, but for surpass them when the fact of price is taken into consideration. Our home manufacturers have fought against the prejudice respecting goods manufactured here, and have succeeded in establishing a reputation for making goods, unexcelled by manufacturers in any part of the world.

On entering the manufactory, the business offices are noticed, as well as processes of manufacture and storage of chocolate, Chartres coffee and spices, which go to make up the stock contained in store, and awaiting shipment to all parts of the Pacific coast, Mexico, China, Sandwich islands, South America, etc. The works are under the personal supervision and management of Mr. D. Ghirardelli, Jr., son of the founder of the concern, the financial affairs devolving upon Mr. Harry Chevesich.

The cocoa employed in the manufacture consists of different varieties and obtained from vastly different sources. The superior article is produced in Tabasco, Mexico, and on the other hand, the cheapest and inferior is obtained in San Domingo, while the quality mostly used is what is called Guayaquil. In the basement of the Jackson street establishment the cocoa is roasted, as also coffee beans, and stored ready for use. Machines for grinding, mixing, making the substance up into hard cakes, moulding tables, a room where is performed the cooling process, etc., constitute the features of a department on the first floor, the adjoining apartment containing offices, storage and packing rooms. On the second floor the same unceasing processes of grinding, cleaning cocoa beans of extraneous matter, and facilitating processes, the emanations of the Messrs. Ghirardelli. Spice mills perform their same unceasing round of duties, and throughout the establishment there is an evidence of busy labor, the importance of which is attested by the high standing of this industry in the business pursuits of the people of San Francisco.

The Divining Rod.

Messrs. Editors:—A sharp discussion is now going on in England, in regard to the dowsing or divining rod. Some claim that it has great merits, while others are equally as positive that it has none. If in the search for and discovery of mineral lodes the divining rod has any merits at all, it is certainly desirable they should be generally known. With this view, I would ask of those of your readers who have had any experience in the use of this instrument themselves, or reliable accounts from others, to communicate such facts to you as they may have ascertained, whether they are for or against the use of the rod.

More *opinions* are not desired; *facts* only are wanted. Veritas.

The Nevada *Transcript* says: A company of English and French capitalists are soon to commence to run a tunnel from the Middle Yuba river into a large tract of gravel, situated near the Backbone house, above North Bloomfield. The tunnel will be in the neighborhood of three miles in length, and it is said it will open up one of the best gravel fields on the ridge.

The Nevada *Transcript* says R. H. Smoot had his eye blown out, check blown off and fingers of his left hand shattered by a premature powder explosion while he was filling a blast at Blue Tent.

The Sacramento smelting works are at present running day and night upon ore from Battle Mountain.

Kern county is the scene of the latest notable mining discovery in the State. A ledge of ruby silver has been found six miles from Keroville. This is the only mine of this character of any magnitude on the western slope of the Sierra. It is stated that the ledge shows vein matter of twenty-two feet, and has been cut through at a depth of 110 feet.

Averill Chemical Paint,
MANUFACTURED BY THE
Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR APPLICATION—requiring no thinner or dryer, and will not spoil by standing any length of time.

It is Cheaper, more durable, more Elastic, and produces a more Beautiful Finish than the best of any other Paint.

It will not Fade, Chalk, Crack, or Peel off, and will last twice as long as any other Paint.

In ordering White, state whether for Outside or Inside use, as we manufacture an Inside White (Flat) for inside use, which will not turn yellow, and produces a finish superior to any other White known.

Put up in ¼, ½, 1, 2 and 5 gallon packages, and in Barrels. Sold by the Gallon.

For further information send for Sample Card and Price List, or apply to the office.

AMMONIA!
For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.

It is unequalled for cleansing Woolen Fabrics, Cutlery, Carpets or Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing.

It renders water soft, and imparts a delightful sense of coolness after washing.

DIRECTIONS.—For Laundry, use two to four tablespoonfuls to a washtub of water. For bathing, use one tablespoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterwards. For stimulating the growth of plants, use a few drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.

Also, SULPHATE OF AMMONIA for chemical purposes, fertilizing, and the preparation of artificial manures. AMMONIACAL PREPARATION, for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing, and PURE LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes.

☞ Manufactured by the

OF INTEREST TO
MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially *machinery for mechanical ore concentration*, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

SAVE YOUR HORSE'S FEET!

NO MORE RASPING AND HAMMERING TO CLINCH HORSE-SHOE NAILS. TENDER FOOTED HORSES SHOD WITH EASE. EVERY TEAMSTER HIS OWN BLACKSMITH.

The new patent implement used is an attachment to an ordinary pair of pincers. A scoop-shaped graver, or chisel, and a flattened, roughened plate, (formed in one piece) are hinged and fastened on to the handle of the pincers. When the forceps are closed the graver projects from one side of the handle, and is retained in that position by allowing the end of the plate to enter a slot between another plate on the other handle, and the handle, thus holding the graver steadily, while the forceps are grasped by both hands, and the grooves cut in the hoof below the point where the nails come through. When the grooves are cut the handles are opened, and the roughened plate turned outward, thus carrying the graver into a slot in the socket, out of the way.

To clinch the nails after the grooves are cut, the handles are opened, and the roughened plate is put beneath the hoof. The edge of a steel plate on the handle of the forceps is then placed above the nail point, and by closing the handles the nail will be bent down into the groove already cut, where it lies nearly flush with the hoof. The plate can be adjusted for large or small hoofs. The groove cut by the graver is about one-eighth of an inch long and one-eighth of an inch wide. No hammering or rasping is necessary. The foot is not bruised or scarred. Any one can learn to use it in a few minutes. Tender-footed horses can be shod with no pain to them. Further information given, if desired, by CHARLES DONNER, Inventor, or C. F. SUHL, Cor. Commercial & Drumm Sts., S. F.

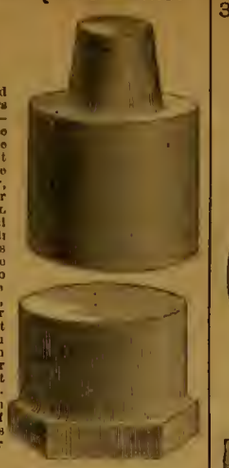
Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.



[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

54 BUSHELS OF CORN AN HOUR.
HARRISON'S
LIGHT VERTICAL BURR MILLS
BARBER & BACON, MILLERS AND LUMBER DEALERS, SOUTH VERNON, VT., write July 15th:
"We have been running two of your LIGHT VERTICAL CORN MILLS for the past 6 months with remarkable results, and have ground over 80,000 bushels of corn into No. 1 meal in that time, running the grist-mill nights only, as we run our saw-mill in the day time. We have often ground in the 20-inch Mill (which weighs about 500 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 24,300 lbs., or 434 bushels. To do this we have to run at a speed of 1,800 turns per minute, and use about a 20-horse power. You may refer parties to us for further information, and when we have tested your HEAVY VERTICAL MILL, we shall take great pleasure in giving the results."

The Concentrating Works at Falun in Sweden—Continued.

[Written for the PRESS by CHAS. C. RUEGER.]

VIII.—The Sorling and Separation of the Sands and Slums.

As repeatedly mentioned above, the combined palp from the rnbhieh works, from the rock breakers and from the Cornish rollere passes into the funnel appsrstus *a* 9 and *c* 8, where it ie condensed, and then ie raieed, together with the battery pnlp and the overflow of the eand jiggere above desigoated, into the eertiog or grading apparatueee *e* and *f*, thie being accomplished by means of the elevators *d* 6 and *d* 7.

Each of these grading appsratuses coneists of the eix V boxes (Germ., Spitzlutten) *e* 1 to *e* 6, respectively, *f* 1 to *f* 6, and of two fannel tanke (Germ., Spitzkasteo) *e* 7 and *e* 8, reepectively, *f* 7 and *f* 8.

The coustraction of the V boxes and funnel tanke corresponds exactly with Rittinger's requirements. The former consist of boxes having two vertical parallel eides, betwcen which are introduced inclined sidee forming with each other an angle of 60°. Inside the space so enclosed a prismatic box is fitted, corresponding in form with the outside casing, and wbich can be raised or lowered with a ecrew, whereby the channels or "limbs" of the V box, formed between the elanting sidee, is enlarged or decreased, cansing the pulp psssiug through the same to assume a greater or leeser velocity.

Two and two of the V boxes correspond iu breadth. The breadth of the first two is one foot eight and a half inches, that of the third and fourth box 2′ 2″, and of the last two, three feet.

The width of the limbs of the V boxes is adjueted to the quantity of pnlp psssing through them, and is generally about one and one-fonrth inches in the first box, and increaees proportionately in each of the following onee.

The grade of sand separated from the current takes its course through a slit in the bottom of the V, which ie one and one-half inches wide, and converges downward to a small discharge hole commnnicating with a wooden pipe attached benesth. Here the sand ie met by a current of clear water, which ride it of slum, by forcing the latter back into the converging slit; while the coarser grade is forced along to a rising outlet pipe.

Out of the V box, *e* 6, the palp flows into the fnnnel tanke *e* 7 and *e* 8, which are provided with two inverted pyramidal compartments. The eurface of the water in the first tank hae a breadth of nine feet, and a length of fonrteen and one-half feet; while that of the eecond tank, *e* 8, ie twelve feet breadth and eighteen feet long.

The conetrnction of these funnel tanks doee not vary materially from that commonly in use (illnstrated in Knstel's book). The shelle of 3″ plank have an inclination of 55° to the level, and are supported by a framework of euitable strength.

Out of the deepest point of the two compartmente of the funnel tanks the pulp pssses npwards, through a three-fourth inch iron pipe carrying a faucet on its upper or discharge end. The graded pulp is discharged into a second smaller fnanel, in which it is condensed, in esse it be fouud too thin; generally, however, it is fouad suitable to be rnn diretly on to the rotating continnous buddles.

The eame arrangement applies to both of the funnel tanks. In the latter of these the current is very slow, so that the slum therein contained ie almost wholly deposited, and the water pussing off at the surface seeme almost clear. Repeated, carefully conducted experimente have shown, that one cubic foot of the outflow water contains only 0.08 lbs. of slum, and this in such a minnte stage of division as to preclude further treatment by concentration.

The sorting or grading of the eande is very perfect; the six V boxes each furnish one grade of sand, and the two funael tanks two grades of slun esch, so that ten distinct grades are produced, which flow directly into their respeo tive eeparating apparatusee.

The disoharge pipe on these grading sppliances seldom choke np, and since there are pluge at proper placee, it is oasy to avoid and remove disturbanoce. The apparatus therefore require no special enpervision, and are therefore attended to by the workmen having in their charge the percuesion tables and buddles, etc.

For the separation of the saude there are at present six Rittinger's continuons percussion tabice, *g* 1 to *g* 6, which are set up in three groups of two tables each, and at various elevations, as suiting the position of the V boxes.

The general construction of theee tables may be assumed as heing knowu, or it is to be found described in the works ou concontration by Kustel and Raymond; the description here is therefore limited to the mention of a few modifications.

The table has the usual dimensions of eight feet length, and a breadth of eight and one-half feet, and is divided by three strengthening ribs into two fields or divisious. Upon the frsme of the table are fastened one and one-fourth inch boards of fir wood, and over these one and one-fourth inch boards of beech, in the abence of a hardor wood. These latter boards are rnbbed off with pumice etone from time to time, and have been foand servicesble. In the emall experimental works—erected to test the varione machines, and study ont the best mode of their application to the ore under treatment, before planning the large works—a table so made hae been in constant uee for four yeare, and is yet in good condition.

Near the lower end of the table esch divieion has two traneversal slite, one for the waste palp, the other for the middlings. The concentrated stuff dischsrges over the lower edge of the tshle, into the conveying sluice provided for the purpose.

Instead of the wooden posts of the ordinary table frames, there are cast iron standards, to which the tables are hung with adjnstable eyebolts. To facilitate the adjustment of the iaclination of the table, the eye-belt nute are provided with handles.

For the guidance of the tsble, a cast iron fork clasps the extreme end of the percussion beam. On the other end of the beam, and on its lower eide, a one and one-fourth inch iron rod is fastened, and passed through the percnssion block. This bolt or rod carries on its outer end a compound rabber buffer, which eerves to propel the table back against the percussion block. This form of spring is much euperior to the wooden oues. Evolute springs of steel are still better.

Esch tsble hse its own driving ehaft of Bessemer steel, foar and one-hslf inches in dismeter, with eingle cam, conical driving palley, and a fly wheel three feet foar inchee in diameter.

In order to be sble to increase or decrease the number of etrokes of the tsble, the line ehaft is aleo provided with conical pulleys. The line ehsft, *h*, lies along the center of the building, one and one-half feet above the lower floor, and psrallel to the length of the percussion tables, so that the motion can be transmitted to both eides, to the tables set up right and leit. The pulp distribntors and olear water slnicee are placed over the head of the tables.

To facilitate the regalstion of the flow of the clearing water, the cocks on the iron water pipes are provided with long rods of one-half inch roand iron, which reach beyond the foot end of the tables, so that the workmen, while regnlating the flow of water, can observe its effeot on the sepsration of the eande.

The graded sands pass from the V box into a distribnting. elnice, from which two transporting slnicee hranch off to the two divieions of the tables, and it is so arranged that the palp from either V box, or from both together, can be given to either table of the reepective group.

The percussion tablee yield rich "emall" ore for smelting, with six to fourteen per cent. coppor, according as the ore containe more or lees magnetio iron; furthermore, middlings and wastes.

The eande contain about one-millionth part gold, or about six ceats to the ton of ore, and yet a great part of it is saved as free gold, by concentration. It is, however, too little to be separated on the ore tables, it is therefore saved on ocntinnously working endless belt tablee, *i* 1 to *i* 6, set np below each percnssion table. These tables are six feet eight inches long and one foot eight inches broad; the belts lie on an incline of two inches to the foot.

The coucentrated small ore, being collected from both percussion table divisione into one sluice, rune into the distributor of the belt tables, and spreade in a thin layer on to the ten-inch wide belt of coaree duck, which being stretched evenly above and below the tsbles, and the ends lapped, is eecurely eewed together with strong twine. At the head end of the table, and above it, ie a clear water elnice, and below the table a squirt-off pipe.

By means of a mechsnical appliance, the endless canvas belt is drawn over rollers, one at each end of the table, periodically, and with a jerking movement, and carriee with it the gold dnst deposited thereon, which, in paseing below the head end roller, is swept off by the squirt pipe, and accumnlated in especial veesele, while the separated small ore flows with the clearing water downwards, to discharge into reeervoirs placed at the foot of the tsble, so thst this gold dust has continually a clean surface to depoeit oa. The gold contained in the enriched small ore thns extracted, is very variable, amounting to about six to thirty-six, sometimes to 170 millionth, or $3.60 to $102 per ton.

The middlings pnlp flows from the Rittinger percussion tables into the funnel apparatus *K* 1 for condensation, then to be raised by the elevator *l* 1 back into the V box *e* 1.

For the "gleaning" of the percussion table wastes, the endlese belt tables *m* 1 to *m* 3 are provided. The construction of these corresponds with that above described; they are much larger, however, the length is eleven feet six inchos, the breadth five feet, and the iuclination per foot one inch. The belt itself is four feet wide.

The product swept off at the head of these tables by the squirt pipe, consisting of impure, poor small ore, goes with the middlings palp from the percussion tablee back into the V boxes. The wastes from the belt tables flow into the fnnnel apparatne *K* 2 for condeusation, to be subsequently raised by the elovator *l* 2 into the sluice *n* for further transportation.

The arrangement is such, that by means of a cam, in connection with a few levers and rods, the belts of the tables *i* 1 and *i* 2, as well as that of *m* 1 are eimultaneously put in motion. The eame applies to the tables of the other groupe.

Twelve lifts per minute are given, each caueing an upward movement of the belt of one and one-fourth inchee, so that on each of the first two tables 62½ equsre feet of belt are washed per hour, and on the larger table 300 square feet in the eam⁹ time.

The wastes from the percussion tables usnally contain 0.8 to 1.2 per cent. copper, and after having passed the belt tables ooly 0.3 or at moet 0.4 per cent. In the experimentsl works, the wastes from the ordinary "plane tables" were 0.2 to 0.4 per cent. richer.

The arrangements just deecribed apply also to the two following groupe of percussion and belt tables, with the difference, only, that the middlings pnlp from the tsblee *g* 3 and *g* 4 flowe with that of the first group into the funnel apparatus *K* 1, and is lifted by the elevator *l* 1 bsck into the first V box, for a repeated grading and separation, while the middlings pulp from the tables *g* 5 and *g* 6 runs, for the same purpoee, into the funnel apparatus *K* 4, then to be lifted by the elevator *l* 3 into the fifth V box.

The attendance aud eupervieion of the six V boxes and six percussion tables, as well as of the six belt tables for the extrsction of the anriferous small ore, and of the three belt tables which serve for the gleaning of the wastes, ie in the hsnds of two men by day, and the same number by night.

For the separation of the slame, there are at present fonr continuous rotsting buddles (called commonly the Hsiz. rotsting buddles), *p* 1 to *p* 4.

The face of the buddlee ie convex, and has sn inclinstion of one inch per foot, outward. The cone of the bnddles has sixteen feet diameter, and lies 3.7 feet above the lower floor, in order to obtain sufficient fall for the middlinge and waete pulps.

The cast iron verticsl ehaft is hollow, ite outside diameter being six inches, ite inner diameter four and one-half inches. It carries a rasette of cast iron, to which are fastened the spider arms of the buddle coue. Further down on the shsft is another raeette, to eapport the braces for the epider arme.

[To be Continued.]

Sulphurets.

MESSRS. EDITORE:—In reply to Mr. Aaron'e letter: If he will have the kindnese to farnieh me with a esmple of the eulphnreted mstter, with the gold ia the peculisr condition which he describes, I ehall feel obliged. After the examination of it I might be able to answer his queetions, and at the same time, perhape add something interesting to my collection: "Laminated gold persietently retaining the color and hne of the grennd eulphurete, after grinding and washing, and which conld not nuite with the quicksilver."

Since 1852 I bave been both owner and manager of quartz mills in different parts of California, and had a caetom mill at Grass Valley for upwarde of ten years, for which mill the commiseionere appointed by the State Agricultural Society in 1858, after a carefnl examination, awarded me the premiam "for the best quartz mill in the State." During all that time, and while working anriferoue rock from hundreds of different veins, I never met with anything like that described by Mr. Aaron.

With respect to the Wsshoe vein-stone, that containing two per cent. of silver mineralized would be worth upwards of $700 to the ton without taking into acconnt the kustelite or argentiferons gold. The majority of the Washoe mills obtain larger results and work mnoh close thaa they are given credit for. They keep accnrate accounts of silver and gold contents of the veinstone worked, and loes on treatment. I would therefore recommend Mr. Aaron, iustead of gaessing at what ie claimed to be esved by the paa process, or listeniug to the gossip of outsiders, to get permission to examine eome of the Washoe mill books, and find out what has really been done at the different mills during the past six months, which would he better thau imagining resnlts and then asking questione about them. If the Patchen process has any merit it will no doubt be adopted, hnt the idea of the Washoe millmen, with their knowledge, experience and energy, eitting quietly down and working their vein-etone with a loss of fifty per cent. of the eilver contents, cannot be entertained for a moment, except by the man who has on sale a new proces to save all the silver and gold. Most of those conversant with mining mattere know that there are three modes of redncing vein-stone—namely, crnshing, stamping and griuding. The first by horizontal rollers and rock breakere; the second by etampers; the third by edge mills, arrastras, pan mills, mill etones, etc. I recommended fine stamping in the Waehoe mills, as being cheaper than grinding with the pans. I snppose when Mr. Aaron speaks of crushing in the batteries that he means stampiug.

I trust Mr. Aaron will not attribnte it to any want of courtesy on my part, bnt I muet decline to answer any other commnnication from him till he furnishee me with a sample of the sulphurets with the gold in the pecaliar condition he describes. M. ATTWOOD.

SELF-MURDEROUS NEGLECT.—To suffer cold to accumnlate on cold, or a cough to become more chronic, when a few doses of HALE'S HONEY OF HOREHOUND AND TAR taken at the outset, invariably effect a cure in a few hours. For sale by all druggists.

Pike's Toothache Drops cure in one minute.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington D.C., Oct. 26th, 1875.

FOR WEEK ENDING OCTOBER 12TH, 1875.*

SEWING MACHINE TABLE.—Walter B. Higgins, S. F., Cal.

HYDRAULIC LIFT DRY DOCK.—Theodore A. Blake, S. F., Cal,

FARE BOX.—Aaron J. Cortie, S. F., Cal.

MACHINE FOR FILLING SEWING MACHINE BOBBINS.—George Gowing, S. F., Cal.

SHORT THREAD SEWING MACHINE.—John S. Hall, S. F., Cal.

GANG PLOW.—Daniel Kendig, Napa, Cal.

SLOTTED FRAMING SQUARE.—John H. McInnes, S. F., Cal.

SEPARATING GOLD FROM OTHER METALS.—Conrad Wiegaud, Virginia City, Nevada.

ICE MACHINE.—John M. Beath, S. F., Cal.

KNIFE SHARPENER AND POLISHER.—Ed. A. Bashnell, Oakland, Cal.

COMBINED PLANTER AND CULTIVATOR.—Chas. F. Keller, Hesldsburg, Cal.

METHOD AND APPARATUS FOR BURNING OIL.—Elisha E. Rice, S. F., Cal.

BRICK PAVEMENT.—Henry M. Stow, S. F., Cal.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

THE SYNDICATE MINING CO.—Oct. 20. Location: Bodi district, Mono county. Trustees—John J. Valentine, John Skae, Andrew Baird, H. M. Yerrington and W. H. Hall. Capital stock, $5,000,000, in 50,000 shares.

COMET G. M. CO.—Oct. 20. Trustees, Wm. A. Levanway, S. H. Harmon, E. C. Burns, S. A. Kelley, L. L. Alexander. Capital stock, $5,000,000, divided into 50,000 shares of $100 par value each.

STOCKBROKERS' S. M. CO.—Oct. 23. Trustees—D. B. Harris, O. R. Johnson, R. B. Kyle, A. C. Taylor, Wm. H. Wilcox. Capital stock, $5,000,000, divided into 100,000 shares of $50 par value each.

MENDOCINO RAILROAD CO.—Oct 23. Object, to maintain and construct a railroad from Cuffey's Cove to a point on Douahne's creek, a distance of five and a half miles. Capital stock, $150,000, divided into 10,000 shares of $100 par value each. Trustees, A. W. Hall, West Evans, James McKinley, George C. Perkins, Charles C. Athern.

GLENCOE CONSOLIDATED G. AND S. M. CO.—Oct. 24. Location: Calaveras county; capital, $6,000,000, divided into 60,000 shares of $100 each. Trustees—A. Lefevre, S. Heydenfeldt, J. W. Brumajim, John F. Finn and L. Leavitt.

SULPHUR BANK QUICKSILVER M. CO.—Oct. 27. Location: Lake county, Cal. Trustees—John Parrott, Wm. Burling, James W. Burling, Tiburcio Parrott and Henry L. Lightner. Capital stock, $10,000,000 in 100,000 shares.

DEWEY & CO.

American & Foreign Patent Agents.

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chili, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advise of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.,

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 224 Sansome St., S. F.

Mining and Scientific Press.

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi.

As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Miners, Assayers, Millman, and Metallurgist in the United States should take it.

Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columns for fresh and valuable information.

Mining Engineers, Superintendents, Metallurgists, Mine Owners and Mine Workers throughout the world should profit by its illustrations and descriptions at New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughout the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

DEWEY & CO.,
No. 224 Sansome street, S. F

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY CUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price $2.50 coin, or $3 currency, postage free

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Mill man, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO $5.

Nevada and California Processes of Silver and Gold Extraction, for general use, and especially for the Mining Public of California and Nevada, with full explanations and directions for all metallurgical operations connected with silver and gold from a preliminary examination of the ore to the final casting of the ingot. Also, a description of the general metallurgy of silver ores. 1864.

As its title indicates, this work gives a wide range of information, applicable to all vein miners and workers in precious metals, affording hints and assistance of exceeding value to both the moderately informed and the most expert operator.

Price, $5 in cloth; $6 in leather—colu.

BY OTHER AUTHORS.

The Quartz Operator's Hand-Book; by P. M. Randall. 1871. Revised and Enlarged Edition. Cloth bound, 175 pages. Price, $2.

Sulphurets: What They Are, How Concentrated, How Assayed, and How Worked; with a Chapter on the Blow-Pipe Assay of Minerals. By Wm. M. Barstow, M.D.; 1867; cloth bound, 114 pages. Printed and sold by DEWEY & Co. Price, $1; postage free. The best written work, and most complete work on the subject treated.

ANY OTHER BOOKS DESIRED will be furnished at the most reasonable rates by DEWEY & Co., Mining and Scientific Press Office, S. F.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THARP—San Francisco.
D. W. CROWELL—California.
A. C. CHAMPION—Tulare, Fresno and Inyo Counties.
JOHN ROSTRON—California.
A. C. KNOX, California.
G. W. MCGREW—Santa Clara county.
CHAS. T. BELL—California, Oregon and W. T.
D. J. JAMES—Australian Colonies.
CHAS. T. BELL—Montana, Utah, Idaho and Nevada.
O. K. LAWTON—Santa Barbara County.

THOUGHTLESSNESS.—Persons sometimes return their paper, marked "stop this paper." Their name being pasted on the sheet they think that is all we need to be able to cross their names off. Now that is thoughtlessness. Your P. O. address is needed as much as your name. We have thousands of names arranged only according to locality. Our mailing clerk does not know where everybody lives.

PASO ROBLES, CAL., October 18th, 1875.

DEWEY & CO.—*Gents:* The letters patent for the Tire Upsetter have come to hand. For the prompt manner with which you have brought the matter to a successful issue, please accept my thanks.

Yours Respectfully, JOHN H. MERTZ.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

UNITED STATES

Mineral Land Laws, Revised Statutes,

And Instructions and Forms Under the Same.

We have just issued a pamphlet containing the general mineral land laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of $500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO.,

A Good Binder for $1.50.

Subscribers or this journal can obtain our Patent Elastic Newspaper File Holder and Binder for $1.50—containing gilt title of the paper on the cover. It preserves the papers completely and in such shape that they may be quickly tasteued and retained in book form at the end of the volume, and the binder (which is very durable) used continuously for subsequent volumes. Post paid, 25 cts. extra. It can be used for Harper's Weekly and other papers of similar size. If not entirely pleased, purchasers may return them within 30 days. Just the thing for libraries and reading rooms, and all who wish to file the PRESS. lamhp

At a Stated Term of the Circuit Court

of the United States of America of the Ninth Judicial Circuit held and for the District of California, held at the court room in the city and county of San Francisco, on Thursday, the 30th day of September, in the year of our Lord one thousand eight hundred and seventy-five. Present—The Honorable Lorenzo Sawyer, Judge.

Nicholas Seibert, complainant, vs. Wm. T. Garratt, defendant—In equity.

DECREE.

This cause came on to be heard at the February Term, A. D. 1875, of this Court and was argued by counsel and thereupon upon consideration thereof, it was ordered, adjudged and decreed, as follows, viz: That defendant, William T. Garratt, was not the first or original inventor, or discoverer of the improvement or discovery claimed by him, in and by those certain reissued letters patent of the United States, number five thousand three hundred and twenty-eight (No. 5328), for an alleged new and useful improvement in lubricators, issued to said defendant, William T. Garratt, on the 18th day of March, A. D. 1873, and is not entitled to a patent therefor, and that said reissued letters patent, number five thousand three hundred and twenty-eight (No. 5328) are declared void and the same are hereby vacated and set aside by reason of their interference with those certain letters patent of the United States, number one hundred and eleven thousand eight hundred and eighty-one (No. 111,881) for a new and useful improvement in lubricators, issued to complainant, Nicholas Seibert, on the fourteenth (14th) day of February, A. D. 1871.

It was also further ordered, adjudged and decreed that complainant do have and recover of and from defendant his costs and expenses to be taxed herein.

(Signed) LORENZO SAWYER,
Circuit Judge.

The above decree has reference to "Seibert's Eureka Lubricator" for oiling the valves and cylinders of steam engines.

It has a glass gauge and condensing pipe, or reservoir, with a regulating feed valve, and works as follows: As the water of condensation is admitted, under the oil, just so fast the oil passes out at the top through a pipe into the steam pipe to oil the valves and cylinder.

Parties who infringe or purchase the infringed lubricators, will be held strictly responsible.

Mining and Other Companies.

Cloverdale Mining Company — Location of principal place of business, San Francisco, California. Location of works, Cinnabar District, Sonoma County, California.

Notice is hereby given, that at a special meeting of the Stockholders, held on the fifteenth day of October, 1875, an assessment, (No. 3) of two hundred dollars per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, No. 306 Clay street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 18th day of November, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 16th day of December, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale. ED. B PARTRIDGE, Secretary.

Office, No. 306 Clay street, San Francisco, California.

Keystone Quartz Mining Company—Principal place of business, San Francisco, California. Location of works, Butte Township, Sierra county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 22d day of September, 1875, an assessment (No. 5) of fifty (50) cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at the office of the company, northwest corner Pine and Sansome streets, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 8th day of November, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 29th day of November, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

LOUIS VESARIA, Secretary.

Office, northwest corner Pine and Sansome streets, San Francisco, California.

Hope Quicksilver Mining Company—Location of principal place of business, San Francisco, California. Location of works, Cinnabar Mining District, Sonoma County, State of California.

Notice is hereby given, that at a regular meeting of the Board of Directors, held on the 2d day of August, 1875, an assessment (No. 2) of Five cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company Room 2, No. 408 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 9th day of September, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 30th day of September, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JACOB HARDY, Secretary.

Office, Room 2, No. 408 California street, San Francisco California.

POSTPONEMENT.—The date of the delinquency of the above assessment is postponed to the 9th day of October, and the date of delinquent sales to November 1st, 1875. By order of the Trustees. J. HARDY, Secretary.

September 8, 1875.

SECOND POSTPONEMENT.—The date of the delinquency of the above assessment is postponed to November 9, 1875, and the day delinquent sales to December 1, 1875. By order of the Board of Trustees.

JACOB HARDY, Secretary.

San Francisco, October 8, 1875,

Orleans Mining Company—Location of principal place of business, San Francisco, Cal. Location of works, Grass Valley Mining District, Grass Valley, Nevada County, Cal.

Notice is hereby given, that at a meeting of the Board of Trustees of said company, held on the 27th day of October, 1875, an assessment, No. 8, of two dollars per share was levied upon the capital stock of said company, payable immediately in gold coin of the United States of America, to the secretary, at the office of the company, room 8, No. 315 California street, in the city of San Francisco.

Any stock upon which said assessment shall remain unpaid on the 30th day of November, 1875, will be advertised on that day as delinquent, and unless payment shall be made before, will be sold on the 18th day of December, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

GEO. P. THURSTON, Secretary.

Office, room 8, No. 315 California street, San Francisco, Cal.

Peytona Gold and Silver Mining Company. Location of principal place of business, San Francisco, Cal. Location of works, Virginia Mining District, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 23d day of October, 1875, an assessment of five dollars per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, room No. 11, 215 Sansome street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the thirtieth day of November, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the 18th day of December, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Directors. F. J. OWENS, Secretary.

Office—No. 11, 215 Sansome street, San Francisco, Cal.

California Planers and Matchers, and Wood Working Machinery of all Kinds

Smith's Celebrated Moulders.

We have four sizes of these Machines always on hand—"B," "C," "D" and "E,"—to work either three or four sides. Have slotted heads and all other improvements, and may be seen in any mill on the Coast. ☞ *Prices reduced* to 15 per cent. less than Eastern list.

SAN FRANCISCO, SATURDAY, NOVEMBER 6, 1875.

VOLUME XXXI Number 19.

The Fryer Process.

Ever since the "Fryer Process" for working ores was first spoken of on this coast, there has been much speculation as to its natare and as to the reaalts it was to accomplish. Rnmor said it was to entirely "revolutionize" the present system of working ores; hnt as that phrsse has been applied to many dozen patent processes before this, and yet the same old system is still in vogue, the shrewd ones didn't believe in it. In fact, it is hard to make mill men pay any attention to "processes," as so many failnres have been made ia times goae hy.

The people who brought the Fryer process here, however, were "Eastern men," who, strange to say, didn't want any capital "to make a few experiments with," or want any oae to make the experiments for them. They did not want to sell the patent; and, stranger atill, had no stock in it for ssle. They looked abont for a placa in which to try their process on an extended scale and selected Grass Valley, Nevada conuty, as a field of operations.

As soon as it wss known that they had commenced to have machinery made, everybody wanted to kaow what kind of machinery it was. As it happened, however, this did not transpire, as whatever was required they had made at several different foundries, ao that no two machinists oonld oompare notes. Some of the machinery wss made here and some at Grass Valley. No stamps were to be nsed; that was evident and was confessed hy the projectors. How were they going to crnsh the rock, then? That was the qnestion. Were they going back to hydrofluoric acid and dissolve the qnartz and try an old experiment which had proven a failure long since? Was it a roasting process, a smelting process, an amalgamating process, or whst?

Strange to say, as far ae the public is concerned, these questions still remain nnanswered, althongh several months have elapsed since the process was first talked of here.

They have kept their secret well, and althoagh extensive worke have heen pnt ap at Grass Valley, and ore from many different mines worked, no one bnt those directly interested know anything about how it was done. The miners themselves owniag the ore do not know anything aboat it. The results of working are stated to be eminently satisfactory to all, as they get a higher perceatage of assay value than by ordinary mill work; and we are informed get more out of the ore at Grass Valley than they even do by the much-vaunted and expensive chlorination process. They get what silver there is, whioh the chlorinators do not.

The owners of the process, who, by the way, seem to care very little what the public think one way or the other abont it, are perfectly certain they can do what they claim. They will have no hesitation whatever in msking the whole thing public as soon as their patents are all obtained. When they are ready they will in all probability let the pnblic know; hut for the present, the pahlic must continne to he cnrious without having its curiosity gratified.

Our friend Mr. W. A. Skidmore, well known among mining men on this coast, and Deputy to the U. S. Mining Commissioner, has heea np at Grass Valley for the past two weeks, and on his retnrn we qneetioned him as to what the Fryer process was, and what it was doing. He does not know anything more ahout the system than the rest of outsiders; says there are no stamps, bnt there ie a steam engine, the lattsr being the only part of the machinery visible to the outside world. He is eatisfied, however, that as far as working the oree np to a high percentage is concerned, the Fryer proces is a success. Moreover, that seems to be the opinion of most of the miners in that seotion. The works are of large capaoity, and expensive. The ore is heing treated hy the ton; not in small lots. It has heen practically a snccess on a large scale, and as far as he can see, will he ia some measnre like milling in this respect: that the ores can be worked cheaper on a large scale than a small, jnst as a 60-stamp mill oan work cheaper thau a 5-stamp mill, the addition of lahor not increasing with the additional machinery.

Mr. Skidmore informs us thst they havo worked a large nnmher of samples of ore for different parties, charging nothing for working it, and invariably returning the gold and silver resultant to the owners of the samples. It seems to make no difference as to olass of rock, free or refractory. They are now working several tons of rock, from the Providence mine, situated near Nevada City, which is oonsidered the most refractory in the State. What they have already worked of this has given good results. This ore is nsually worked by chlorination, but this process is said to have worked the ore better than the chlorination, saving considerable silver ss well as the gold.

The expense is a trifle more than the ordinary first-class milling treatment, but all the precious metals are saved. The operators claim thst they are able to save ninety-five per cent. of the assay value in any class of rock, no matter what the gangne matter may he.

There is no water nscd in this process; that is, the rock is not snhjected to the action of water at all. The system is fonnded on the fact of the extremo divisihility and atomic chsracter of gold in rock.

The gentlemen interested in the procese, and who have "pnt np" the money, came out from the East recently and last week visitod the works. They are all completely satisfied that the thing is a saccess and have retnrned home again. Mr. Fryer himself is no more adventnrer. He is well known to a number of the gentlemen comprising the company. He is an iaventor of some note, and although a man not more than thirty years of sge, has already perfected a nnmber of very importsnt inventions. He has come here to make his home, and has proved coaclusively to those who have assisted him to perfect his process that he can do what he claimed. It is understood that as soon as the company's arrangements are perfected the right to use the procese will he sold for a very small royalty, so that no very extensive capital will he required. We notice that the Nevada county papers have abiding faith in this process, having become convinced that it is a perfect success. Skeptical persons, however, will naturally desire to eee the works and learn the rationale of the process before helieving in it completely.

The peaks at the Summit are now covered with snow, which fell on Thnrsday. Snow fell in Tnckee, hut only in a mild way. It quickly disappeared.

The Grass Valley *Union* says: "It is reported that the hank of Findley & Co. will he reopened soon and everything satisfactorily adjasted."

An Improved Floor Clamp.

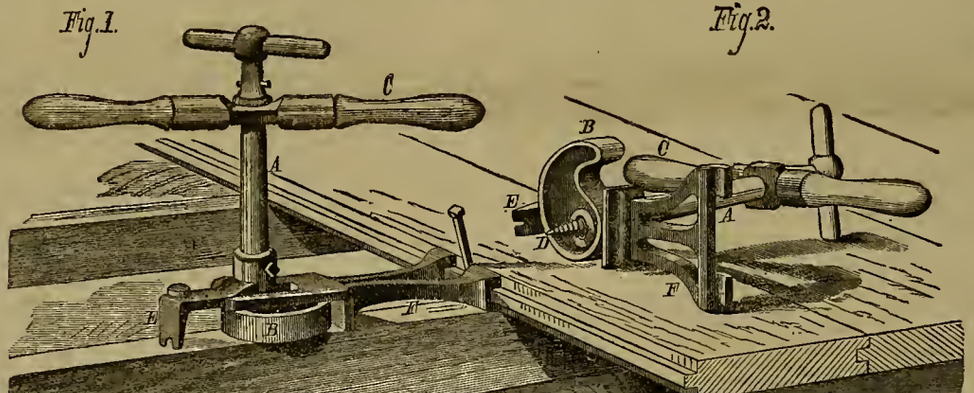
We illustrate herewith an inventioa of especial interest to house carpenters, cabinet makers, oar hnilders and others reqniriag an effective clamping tool. This floor cramp is patented hy W. D. Clarke, of Springfield, Illiaois, and is fnlly desoribed as follows:

It consists of a sleeve, *A*, which at its lower extremity carries a cam, *B*, Fig. 2, and st its upper end has a handle, *C*. Passing through the sleeve, is a rod having a screw point, *D*, at its lower end, and tnrned hy the npper handle shown. Attached to a oollar on the sleeve, *A*, is a rearward extending arm, *E*, the end of which is turned downward and toothed so as to engage with the sarface of the joist or floor. *F* is a slotted or grooved arm which is pressed by the cam agsinst the boards when said cam is snitably revolved by the handle, *C*. The holding arm *E* prevents any rearward motion of the device which is still fnrther secured by the screw point, *D*, entering the wood of the joist or floor. Althongh the device is designated as a floor olamp, it can be used for any pnrpose where a clamp is required, such as clamping doors, sash or articles of fnraitnre, or, in short, anything reqniring a strong and continons pressnre.

We think it wonld be of service in laying deck plank on vessels, where close fitting joints are so necessary.

The immense pressure exerted and the ease and readiness with which the machine can he spplied will, no douht, recommend its nse to carpenters, cabinet makers, car huilders and others having need af an efficient clamp.

The mschine is very compact, occupying but little space, and osn be placed in auy carpenter's chest.



CLARK'S IMPROVED FLOOR CLAMP.

At a meeting of the citizens of Santa Clara, to ohtain snbscriptions to the narrow gauge railroad, to be rnn from deep water on the hay to Santa Clara, thence throngh the Redwood district to Santa Cruz, a committee was appointed to solicit snhscriptions and to report at a meeting to he held next Saturday evening. In the event of $50,000 being snbscribed, the company will locate their principsl offices and shops there. Mnch enthnsiasm is manifested, and no donbt is entertained that the requisite amonnt will he raised.

The Black Hills.—It appears after all that trouble between the Black Hills gold hnnters and the Indians is inevitable. The Sioux City *Journal* has the following, whioh ie snggestiee: "The Black Hills excitement has not all died away, and in fact there ie considerable heing done hereahouts in a quiet manner. Several partiee arrived yesterday in this oity with the intention of making their way without mnch ado into the repnted gold country to pass the winter."

Judge White, the new Chief Jnstice of Utah, arrived in Salt Lake on the 24th nlt.

Our Home Industries.

Maccaroai, Vermicelli, Farina, Etc.

In speakiag of manufactnres it seems to ns a truism, and one beyond aay reasonable doabt, that the iacrease and perfection of basiness occnpations, or art of manufacture, is not so mnch on acconnt of the proportionate increase of popnlation every decade, bat definitely constitnted so, from the faot of specializing business pnrsuits.

We can here trace the csuse which makes the people of this age snperior to those of the past; the fact of individuals devoting special attention to any particnlar pursuit or branch of what once helped to form a certain trade, and the perfection accomplished in the nndertaking tending strongly to the expression we made, that we are a progressive people, and aided considerably hy the knowledge of individuals respecting distiact trades, which once only helped to form a corollary or whole.

The preparation or mannfacture of Italian pastes, maccaroni, vermicelli, farina, etc., in this conntry, and particnlarly in this oity, may be stated as being of no very recent origin, as the hasiness was began in 1853, by a firm—Messrs. Brignardello, Macchiavello & Co., at qnarters Nos. 704 and 706 Sansome street, the qaarters now occnpied hy their snccessors, the California Italian paste company, whose establishment is the largest in point of production in the Uuited States. The business of which we treat, has for its sonrce of supplies not only the conntry west of the Rocky monntains, bnt extends as far Esst as St. Lonis, while large shipments are constaatly made to Mexico, South America, Sandwich islsnds, Japan, China, etc. This fact affording evidence of the importance of the pnrsuit and its high standing in the general trade indnstry of the city.

The Messrs. Prusso & Splivalo have carried on this interesting pnrsnit, in their own right, for the last two years—the gentlemen having formerly participated in the business as the "Co." of the firm which inangurated the bnsiness in San Frsncisco, in 1853. They have bccome practically edncated in the bnsiness; and to their profioiency may be ascribed the snccess which has heen achieved of late years, an acknowledgment of which has been attested in the faot of obtainment of first preminm for goods of the description named, at the Mechsnics' Fair, lately held in this city, and possession of similar testimonials awarded them on other occasions of a similar nature.

The superiority of the firm we speak of does not solely rest npon the proficiency of the members, though to this fact may be ascribed the excellent condition of their mannfactnres; bnt also is dependent npon the excellent and superior qnalities of wheat which they raise in different psrts of the State of California; the oereals here produced heing acknowledged to be the hest in the market. It also adds to their favor when we remark, that it is the only firm in the conntry which employs a similar qnality of whest in the manufactare of Italian psste.

The property occupied by this firm oonsists of 50 feet front, on Sansome street, and extending to the depth of 137½ feet—the entire space occupied by building, in which has heen introdnced machinery of the latest style and description, and particularly adaptable to the production of large qnantities of the several varieties which constitute the mannfactnre, as carried on.

The trade of this establishment, controlled by Messrs. J. Prusso & C. R. Splivalo, is exclusively wi'h wholesale dealers, in the direction of conntry we have named, whero the superiority of their goods have won for the honse a high standing, the degree of commercial snccess achieved by the firm ranking their establishment as the most prominent of its kind in the conntry.

CORRESPONDENCE.

Travels About Santa Rosa.

MESSRS. EDITORS:—Peeks of the Coest range loom np in plein view from Santa Rosa, sherply defined egeinst the northweet horizon, more than twenty miles ewey. On a cleer day the huge redwoods are so distinctly vieible thet the iutervening distence seeme hardly five miles. But a trip there consumes four houre' herd driving, end develops deep canons, e river of respecteble size—a hundred miles long—and the remeins of oue of our meguificent redwood forests, now producing, from four mills, about one hnndred thousand feet of hoards daily.

Whether the writer went there a few deys ego to pleese his fancy for the romantic, to gather stetietics, or as an envoy of the Lick trustees to select a site for the observatory, is nobody's business. Bnt it is certein thet he was provided with one of the heet four-horse turnouts for the occasion; fare, $2. Ten miles of the road lies through the Santa Rosa valley. Farm-honsss, orcherds, fields aud cattle dot the landscape on every hand. The late harvest has heen a plenteous yield and prodncts bring fair prices. One well-known farm, finely improved, with all necessary huildings, a large bearing orchard, ten acres of grapes, excellent fences, and a eituation es heartsome as the September picture on the page of an old almenac, where we used to eee, in our boyhood, the thrifty farmer sowing his grein—can he purohased for $45 per acre. These are 160 acree, three miles from the city; unimproved lands are lower in price. Fifteen miles out we entered the Russien River valley throngh Pocket canon. The first saw-mill ever erected in this region was here, at the intersection of Oregon canon. It was removed in 1858, by Sedgley & Miller, to a poiut lower down, neer Dr. Alden's place. There, hy the way, is a fine patch of cultivated hlackherries, which grow without irrigation. Torrence huilt a water saw-mill in 1861, still further down the stream, which did a thriving husinese until he thinned out the timber. The dam and building, and a few rotten saw logs may be seen yet. At that time no one thonght the redwood wilderness heyoud the river would be cut off for generations. There was no settlement at Stnmptown, which is in the heart of it, until 1867, when Heald & Guerne erected a saw-mill there, and Mr. Guerne, nnfortunately, gave his name to the place. For the sake of euphony let them select an easier name. One redwood standing in Torrence's field, acroes the river from Stumptown, measures fifty-four feet in circumference, a single etem, and 340 feet in hight.

Every few rods on our wey down the canon we met huge lumber wagone, drawn by four or six horses, when we had to give the road and wait for them to paee hy in cloude of dust. Now and then we started up flocks of quails, and onoe we saw a deer feeding with some cattle. It was eome consolation to think we wonld not have seen any game if we had had a gnn along. Betwoen times, when not delayed by teams, we tried to make np lost time. Our wheel horses were mules—good for holding back—though under the exhortatione of our driver they cantered as gracefully as a couple of cows coming from the pasture, each with a boy hanging to her teil. The driver of our mail hack invariahly waters hie team at the "Humming-hird saloon" hefore reaching the river. Why? will always remain a mystery with him, nnless he, too, is in some way connected with the observatory. For it was hore thet our expedition developed some eigns of a scientific charactor, by teking several observatione of a celestial nature through tho bottom of beer glaseee directed toward the zenith.

The channel of the river is about 500 feet wide and thirty feet deep. A stream of clear water, fifty feet broad and knee deep, ripples over the pehhles, where one cannot help looking for stray nuggets of gold that may have heen overlooked. A hoy is watering a horse, mid-side deep in a pool, up the stream. Tha horse turne with a snort and a plunge, making the spray fall like showers of diamonds in the setting sun-light, and canters across tho sand ahead of us into the village. The driver cracks his whip, his leaders hreak into a gallop, and we make our triumphal entry into Stumptown. Though the Octoher day had heen hot, a delicious coolness came with tbe evening seahreeze end pervaded the air. The sun set behind a neighboring mountain, covered to the snmmit with trees, and long rays of yellow light streamed across the valley, which, with the river, the village and the forest helow, soon faded into the sober gloom of twilight. It was very pleasant to sit on the porch after supper, leaning back in a split-hottom chair, reeting and looking at the strango scenery. Rough men, wearing fancy shirts and big hoots, droppod in, one hy one, to gossip with the stage driver, fishing for hits of news from the county seat. A party made up a game of "seven-up" at the har-room table, and some dogs were stretched before the wood fire on the hearth.

In the morning we waked up and peered through the winaow at gigantic redwoods, standing like church steeples, propping wreaths of fog which crept up the river through the night from the ocean, only ten miles distant. We brought a good appetite to the hreekfest, presided over hy Mother Teggert. There was a snowy cloth, with venison steak, hem and egge, hot rolls, hutter cekes, golden hntter, coffee with creem, and so on. After paying a very modest bill we took np the line of march, on foot, through "Big Bottom," the finest hody of redwoode south of Hnmholdt hey. At the outset we passed a mill, where the tanhark of this region is ground and sacked for the city market. Rough berk eells for ten dollers a cord, of two thousand ponnds, delivered at the mill. The hills are full of the oek producing it, and the industry is so well paid for thet squettere are foraging over the lands of our Uncle Samuel, in defiance of the law. A mile further we pess e saw mill, in the midst of the largest timher. The office stends on a stump, and many of the stumps thereahout ere ee hig as the houses. Six yoke of oxen were drewing a log over the skid roed. Ae we leaned against a tree, viewing its pessage, the nine-foot monster jolted the eolid ground and the tree hehind us. Continuing a couple of miles to the head of the valley, at Batchelder's, we passed through a thick iorest of immense trees, etanding so close it is estimated they would eaw more than one hundred thonsand feet of inch hoerds per acre. As commonly piled, there would he a hoard yard covering the surface of the land. Many single trees will cut forty thousand feet of clear lumher. There may he two hundred millione of redwood lumber remaining in "Big Bottom" and its neighhoring canons, hnt the estimete is large.

North of San Francisco there are few other redwoods for supplying the Santa Rosa and Napa valleye; hnt everywhere there is a sprinkling of fir, on the hills, for freming timber and rough uses. There are elso great quantities of oek, madrone, end other woods, good for fnel. The city ie reaching ite iron arms towards thie forest already. A railway *via* Tomales, and one *via* Santa Roea, will soou cross the Russian river. At uo distant day, when the land ie cleared, the eoil will be found very veluable for agricnlture—corn, alfalfa, potatoes and melons succeed finely on the low, alluviel lands. The various kinds of fruits and grapes will doubtless grow on the hill sides, especially where there are springs that may be used for irrigation. Oue drawhack will he, the trouhle of working around the stumps; hut redwood roots lio very deep and the plow can he run close. As this timher fires easily, perhaps they can he hurued out with kerosene oil. There are numerons instances of decayed trees hurning ten feet below the surface. The eoil is from five to twenty-five feet in depth, of a rich deposit of eilt and mold, where plant roots readily penotrate and draw enpplies. At present these lands, where denuded of timher, are reckoned of little value by the lumbermeu. Ten years hence, in the hands of a thrifty popnlation, almost every acre can he made to yield its harvest. I will make the statement eo plain no man can misnnderstand it—that every product of the soil in middle Californie will, and does, grow on these alluvial lands without irrigation.

For several days the writer was employed in surveying thereahout. The lines often ran over hills and gnlches where it was hard, slow work to olimb, and not at all hard to descend if one likes sliding. Each day, at noon and sunset, the mines in Mt. Jackson fired off eharges that echoed and re-echoed through the hills, signals for quitting work. At night, the eilence of the forest was unhroken around the cahin where we slept. It was overshadowed hy redwoods and fragrant laurels, which let in glimpses of the firmament through lofty branches, that seemed to move against the stars.

Now is ths time for men who have faith in the future to go in, ahead of the tide of improvement and speculation, to secnre small homes. The railwaye will bring both. True, the conntry is new, hut time and labor will round up and soften ite rough face. Those who weit aronnd the cities and settled portione of the State, expecting to drop into livee of pleuty and luxurione ease, may ae well stay away, hearing in mind that the primeval curse of labor still rests upou mankind.

J. B. ARMSTRONG.

Santa Rosa, Cal., Oct. 20th.

ORO FINO.—The rich strike in the Oro Fino is developing hetter than even the most sanguine friends of the mine expected. It is found very rich between the 2d and 3d levels, hoth north and south of the shaft. In some places the ledge is from 12 to 14 ft wide, and will averege from 5 to 6 ft in width of good ore, the richest streak heing ahout a foot in thickness and literally filled with coarse, free gold thet does one good to look at. Superintendent Catalow offered to bet last evening that within ten daye from now he could select a ton of ore that wonld mill over $10,000, and he found no takers. The deposit gete richer, the more it is developed, and promises to he an extensive and permanent thing. The mine is now yielding over a ton of ore per day to every man employed in and ahout the mine. The hullion product of the Oro Fino for the current month will he considerably over $40,000, and, if the present rich strike holds out, there is no telling what next month's product will be.—*Idaho Avalanche.*

THE highest mountain in the world has been discovered again. It is in New Guinea, and ie said to he 32,783 feet high. They have ohristened it Mount Hercules.

The C. & C. Shaft—An Immense Engineering Work.

Tbere can be no doubt that the engineering skill displeyed in sinking the new combination shaft of the California and Consolideted Virginie compenies hee heen superior to anything heretofore seen on the Comstock. When it was determined to sink a ehaft to the eastward to touch the bonanze at a point from which it could he worked more advantegeously than from eny other, speed in sinking end en eerly completion of the work were considered all important. To this end every modern applience wes introduced and the experience of the oldeet Comstock minere brought into requisition. The repidity with which the shaft ie being pnt down ie worthy of remark, four feet a day heing the rate of progress. This morning a *Chronicle* reporter visited the shaft, and took a few notes of what had been done and what is now going forward. Ahont seventy-five men are employed on the surface, putting the machinery in order and finishing

The Buildings.

These latter are large and substentielly constructed, the main hnilding being 120 by 50 feet. This merely covere the hoisting engines and the shaft. On the north side of the boiler room, containing three sets of boilers, are the dressing room for men, the office for the timekeeper, hath room, store room, etc., the whole covering an area of 120 by 60 feet. On the south eide are the carpenter and machine shops. There are two carpenter shope, built independently of each other, with an intervening space of fifteen feet, the one being for use in framing and fitting timhers for the California mine and the other for the Consolidated Virginia. They are each 40 hy 80 feet, the one nearest the shaft having a heesment. Parallel to these, on the west, is the mechine shop, 34 by 80 feet, in which lathes, air-compressore and mechines for doing the iron work of hoth mines will be placed. This room ie not yet completed, however, the sills only being laid. The othere are all up and enclosed.

The Hoisting Engines.

The machinery at the C. & C. shaft strikes the observer, nnless he be a practical machiniet, as being immensely complicated. The engines contain all the latest appliances in mining mechinery, and are as perfect as man'e present knowledge of mechanics can make them. They were designed by W. H. Patten, the architect of the Consolidated Virginia mills and several other worke on the Comstock. There are two hoisting engines of twenty-six inchee in diameter and six feet stroke, operating directly upon a ehaft eighteen inchee thick in the center and sixteen at the ends. By thns having the engine cranke directly upon the shaft, the loss of power in friction of gearing, together with the cost of euch gearing and the danger of breakage, are avoided. The cranke are of wrought iron, the pins and piston rods being of steel. The engines are supplied with Cornish double-beat valves and cross-cuts off. They look to the unpracticed eye something like the incline enginee at the Savage, hut differ from these in eome of the detaile of conetruction. They are estimated to have power sufficient to hoist from a depth of 4,000 feet.

A New Safety Brake.

Attached to the hoisting engine is something in the way of a safety brake, which reflecte credit upon the architect of the machinery, and is something which miners, above all others, will appreciate. By an ingenious arrengement of levers, a powerful iron brake strap, which nearly eucircles the fly wheel, ie operated hy a couple of small steam cylinders placed under the floor, eo thet, should the cable he overwound and the cage he on its way toward tho sheaves, the steam from the cyliudere of the engine passes into these small cylinders and the hoisting is instantly stopped. This transfer of the steam is effected hy meane of an indicator, which is itself something new. It ie a perpendicular rod ascending a perpendioular scale, one foot indicating one hundred feet of the shaft. Shonld this indicator be carried above tho mark described, hy over-winding, as above steted, it oporates instantly upon the small steam cylinders and an immediete stoppage is secnred. There are many other points ahont the hoisting engines that are worthy of mention, such as the putting on of the clutch on to the shaft hy an octangular fib, instead of with feathers—the usual way.

The Pumping Engine

Is a monster of its kind, and is novel in its construction, working also so smoothly and so much like a thing of life, that it is worthy of a visit from the ourious. The diameter of the cylinder is forty inches and the etroke eight feet. The pieton ects directly upon the heam of the pump, hy means of a large wooden conuecting rod, thus saving, as with the hoisting engines, a great deal of friction. The engine is supplied with that very intricate machine, the cataract valve, and can be made to perform one etroke per minute, or ae many more as may be desired. At present two strokes per minute are sufficient to keep the water out of the shaft. The ordinary pumping engine cannot he reduced helow four or five etrokes per minute, eo that where the water comes in hut elowly there muet he some unnecessary labor performed. The adaptation of the cataract valve to the pumping engine is due entirely to the study of Mr. Patten. Some time ago it was charged hy a flippent newspaper writer that thie gentleman olaimed the invention of the valves. It is almost needless to say that ths charge is ridiculous, inesmuch as the invention was mentioned, we believe, in an English pnblication on practical mechanics, by John Bourne, eome ten yeare ago. Davis subseqnently improved upon the invention, and the adaptation to the Cornish pumping engine, ee eaid before, is dne to the ingenuity of the architect of the C. & C. works. The engine and the eteem piping ere covered with Salamender filling, the new preparetion for saving heat, and conseqnently eteam. The filling is a wonderful non-conductor, and the engineers think it is a valuable acquisition for an engine. The pnmping engine ie situated, as might have been remarked before, npon the north eide of the hoisting department, and is about ten feet below the level of the hoisting engine.

The Gallows Frame, Etc.

The gallows freme, it was intimated when the works were begun, would be built of iron, ae wood soon rotted away, the constantly ascending steam from the sheft keeping it continually moist. A sort of sprnce pine, however, was got from California, which, for a long time, withstande decay, and of this the frame has been built. The main uprights are abont two feet square, with double trestles thrown across. The frame ie forty feet high, and ie braced with iron and wood in the most thorongh manner. The sheaves, or pullies throngh which the cable runs, are twelve feet in diameter. There is a double floor immediately aronnd the shaft, with a space between of eight feet. The rock will be hoisted, for the most part, np to the second floor, the lower one heing used for loading short timbers for deecent into the sheft. The lower floor is on a level with the basement of the carpenter shope. The blacksmith shop will be on the east side of the main building, bnt is not yet very neer completion. The whole arrangement at the C. & C. sheft betokene skill on the pert of the mechanics, and a desire on the part of the owners of the property that it shall last at least a few ages.

The California's New Mill.

The California's new mill, at Six-mile cauon, commenced on the 19th of April last, is another enterprise that ie making rapid progress, under the superintendence of Mr. Rooney. It will be ready by the 15th of November. It is the largest of its kind on the coast, and therefore in the world, and will be one more wonder for distingnished visitors when finished. It is 150 feet long hy 92 feet hroad—thirty feet longer than the Consolidated Virginia's—and contains forty pans, twenty setting and two cleaner pans. The agitating room, which measures thirty-two by ninety-two feet, contains four agitators, two pans and two settlers. The pan-frames are two feet higher from the floor then those of the Consolidated Virginie, thereby giving much easier access to the bands, etc., helow. The boiler room ie very epacious and solidly huilt, and has in it four sete of hnge boilere. It and the engine room meaenre together eighty feet. The retort house and blacksmith ehops, which are deteched from the main building end built of brick, are jnst being commenced and will meaeure 80x24 feet.

The New Style of Blasting.

A great deal of heavy work had to be done in excavating the foundation for the mill, as the grade npon which it ie built is so steep that a depth from seventeen to twenty-four feet had to be roacbed through eolid rock to obtain a level. Mr. Rooney need a churn drill, making the hole fifteen or twenty feet deep. In this he placed one or two cartridges of giant powder, which, whon exploded, formed a large chamber, and in this the final blasting charge of black powder wae placed. So effectnal is this process, that one blast kept seventeen certs hnsy for three days in removing the debris of the explosion. This was at the Consolidated Virginia works, the only other place at which Mr. Rooney has blasted in the manner prescribed.

The new mill will he well protected against fire, as three hydrants are placed around it, each throwing a magnificent stream of water, more powerful and greater in volume than any steam engine in thie city could supply. At present 140 men are at work. When completed tbe mill will give employment to over forty men, and will crneh abont 275 tons per day.—*Virginia Chronicle, Oct. 22d.*

ALTURAS MINES.—Correspondent Idaho *Avalanche*, Oct. 23: In former lotters to the *Avalanche* I have endeavored to give an nnprejndiced view of the condition, etatus and prospecets of the minee at Rocky Bar and Atlanta. I have represented them as I have found them, not deeming it necesary to make comparisons, disparaging or otherwise, with other camps, hut desirons of aiding to make them known abroed, believing ae I do, that as soon as live capitalists of the Pacific elope find out what there is here, there must unavoidably be a more healthy development and conseqnently a greater increase of popnlation and prosperity. With good management these mines cannot fail to prove an immense source of wealth, and there is no reason why season after season ehonld elapse without their being teken advantage of and mines worked snccessfully. The mammoth ledge in the vicinity of Atlanta is capable of yielding bullion to the valne of millione of dollare, and why should not the advantage of ench a development he reaped at present? There are many emeller minee, also, that ought to he made more productive and give employment to a larger number of men. More capital to develop and hetter management are the great wante of the camp at present.

Scientific Progress.

Geological Importance of the Colorado Explorations.

Very few if eny explorations heve been undertaken which have been pushed forward so rapidly, or resulted in euch important developments, as the recent explorations in the Colorado basin. The immense canyons there have been the result of river erosion rapidly carried on in soft sandstone, and the almost total absence of rain in that region has preserved the results of the erosions almost as intact as if they had but recently been made by artificial means. Hence, the opportunities for studying the geology of the country are extremely favorable. That region is also particularly rich in geological developments.

The extreme barrenness of this region is due to the fact of its great depression—so great that the salts and all the soluble matter contained in the ancient sea which once covered it, have been left in the soil. The soil has never been washed of its impurities as have most other portions of the globe, because its waters have had very little opportunity of finding their way to the sea.

The explorations show that that region has been "lifted up from the ocean's bosom three times; that three times the rocks were fractured, that three times the lava poured out of the crevices, and that three times the waters carved out valleys in their course seawards. The first of these periods was after the formation of the granite rocks; the second succeeded the sandstone formation; the third period is the present. The remnants of the first and second periods are buried; but we know that unnumbered centuries ago in the past, the granites and schists, now on the bottom of the grand canyon, were formed as a sedimentary bed beneath the sea, that then an upheaval took place, after which thousands of feet of beds were washed away in the sea by rains; then a depression took place, sinking the whole region some 20,000 feet below the ocean's surface, and allowing the formation of sandstone, at least 10,000 feet in thickness, as a sediment; then a second upheaval came, changing it again into dry land; then the rains washed away channels in the sandstone 10,000 feet deep, requiring countless years of gentle but unrelenting energy. Again the sea rolled over the land, which became its bottom, and received a new deposit of more than 10,000 feet of rocky bed; and lastly, this ocean bed was again upheaved, and for 100,000 years the atmospheric influences and the running streams, gathered from the clouds in the highest mountain tops, have been making gorges, canons and valleys, and carrying the *debris* back to the sea, from whose bottom the material all came."

The period of time required to form this successive deposits which have been opened up to view by the immense canons of the Colorado, must have been enormous; and in view of its present extreme depression and past uncertain stability, the question naturally comes up: "Will not the sea, at some future period, invade that land, by the sinking down of the latter, and will coral reefs be formed, and serve perhaps for the burial of the bones of the beings which then shall exist? Will the surrounding continents or islands be washed into that sea and form new beds of rock, which, when again upheaved, will form a new land, and canons again be formed, and reveal in their walls, to another race of intelligent beings, some of the features of the time in which we live at present?"

Discovery of a New Metal—Gallium.

Gallium is the name given, "in honor of France," to a new element which has been discovered by M. Lecoq, an amateur *savant*, of Bois-Baudran, Cognac. The celebrated chemist, Wurtz, presented to the Academie des Sciences, in its sitting of September 20th, a note on the part of M. Lecoq, announcing the discovery, particulars of which had been communicated under seal as far back as August 27th. This new element has not yet been isolated, and has not therefore been seen by any one; its physical characteristics remain so far unknown. It is an analogus of zinc and cadmium, of which metals it is an alloy, and was found in a blende from Pietrafita, Spain. The forms under which it is known, so far, are those of the chloride and sulphate. The discoverer is a student of the phenomena of the spectroscope, and it was in the course of his observations that the new metal presented itself, its character being revealed by a spectrum which no simple body had ever given. Two lines, one much brighter than the other, both situated in the violet—the region occupied by the brightest lines of the zinc—were noticed, the place of the former line being at the 417th degree of the scale of lines, and the other at the 404th.

The affinities which gallium has with zinc are declared by chemical analysis as well as by its spectrum. Like zinc it is not thrown down from solution in hydrochloric acid by sulphuretted hydrogen; and preserves its analogy with zinc by being precipitated by the same gas from an acetic acid solution. Under these conditions it is obtained before the zinc, and on fractionation, the two are got separately. Like zinc, the new metal gives a white precipitate with the sulphide of ammonium. On immersing a piece of zinc in a solution of the new metal it separates and comes out, not in a metallic form, but under that of an oxide, precisely as aluminium does under similar circumstances. The analogy with aluminium, however, is not long sustained, for if a small dose of ammonia precipitates the gallium, an excess redissolves it. Up to the present time, only a very small quantity of gallium has been obtained, but M. Wurtz, who presented the paper, has given the academy tubes of solution for experiment; and on asking for a commission to examine into the question and to place gallium on the list of simple bodies, the academy named M. Wurtz himself, joining with him M. Fremy. The actual number of known elements is sixty-three—forty-seven of which are metals and sixteen metalloids. If the new element takes the place claimed for it, France will have obtained an honor equal to that of England, which discovered thallium, and approximative to that of Germany, the discoverer of cæsium and rubidium.

The Magnetization of Gas Spectra.

Some very curious experiments have recently been laid before the French Academy of Sciences by M. Chautard, relative to the influence of a powerful magnet upon the spectra of gases contained in Geissler tubes and illuminated by means of the electric current. In all simple bodies of the chlorine family, and in the gaseous or volatile compounds derived therefrom which thus far have been examined, the action of the magnet is immediate, and manifests itself, not merely by a change of color in the tubes, but by an increased brilliancy of the spectral lines, which become doubled. The bodies thus far submitted to investigation, besides chlorine, which behave similarly include bromine, iodine, the chloride, bromide and fluoride of silicium, the fluoride of boron, hydrochloric acid, chloride of antimony and of bismuth, bichloride of mercury, and the protochlorids and bichloride of tin.

The lights of sulphur and of selenium become extinguished the instant the magnet is excited, and the same is the case with that of the tubes containing chlorine, bromine, and iodine, when the tension of the coil is suitable. The feeble brilliancy of the oxygen illumination is not sensibly modified, nor is that of carbon compounds, such as carbonic acid, carbonic oxide, etc. The fine bands of the nitrogen spectrum are not changed, except in the red and yellow portion. These colors become almost completely extinguished, or at least are replaced by a flat uniform tint, in which all traces of lines disappear. The lines in the more refrangible region remain intact.

The hydrogen lines keep sensibly their normal appearance, but by employing a sufficiently powerful magnet, at the moment of excitation a very brilliant yellow line appears, which is due to sodium, doubtless obtained from the surrounding glass. This line vanishes as if by magic when the current is interrupted, to reappear again, however, for some time, as often as the electric flow is established.—*Scientific American.*

Steam as a Magnetizer.—Steam has been used as a source of electricity in the steam electric machine of Sturgeon, and now it is announced by Donato Tommasi as a source of magnetism. He states that if steam of five or six atmospheres pressure is passed through a copper tube of one-tenth of an inch in diameter, wound as a helix around an iron cylinder, the iron will be magnetized, and attract other iron, act on the compass-needle, and manifest other phenomena. This simple discovery, if correct, opens a new field of investigation. The first matter for investigation must be to compare the steam current with the electric current, and to find if steam corresponds with the positive or with the negative current, that is, if the boiler giving the steam corresponds with the zinc pole of the battery or with the other, (carbon, platinum, etc.,) which question is easily settled by observing which end of the iron bar acquires north or south polarity. The next point of investigation is the increase and decrease of this polarity with the increase and decrease of steam pressure.

What is the Sun?—Professor Randolph, in a lengthy paper on the sun, says: "A molten or white hot mass, 856,000 miles in diameter, equalling in bulk 1,260,000 worlds like our own, having a surrounding ocean of gas or fire, 50,000 miles deep, tongues of flame darting upward more than 50,000 miles, volcanic forces that hurl into the solar atmosphere luminous matter to the hight of 160,000 miles, drawing to itself all the worlds belonging to our family of planets and holding them all in their proper places, attracting with such superior force the millions of solid and stray masses that are wandering in the fathomless abyss that they rush helplessly toward him and fall into his fiery embrace. And thus he continues his sublime and restless march through his fiery orbit, having a period of more than 18,000,000 years.

Oxygen Gas, when inclosed in a thin glass tube, will show itself under the action of a magnet to be paramagnetic, inclining north and south like iron; and while nitrogen, hydrogen and carbonic acids remain unaffected, phosphorus, leather and wood show themselves to be diamagnetic, and arrange themselves equatorially from east to west.

Mechanical Progress.

More About Compressed Steel.

We recently gave, in these columns, a lengthy article on the gigantic efforts which are now being made in Europe to cast steel under powerful compression. The costly experiments and works which have been undertaken in this direction afford ample evidence of the public estimate which is placed upon the most perfect production of this class of steel.

The process of compressing steel in the liquid state, says *Engineering*, is one which we must regard as rational if ingots cannot be cast commercially without being more or less honeycombed; but going to the root of the matter, we are led to inquire how far this honeycombing is a necessity.

It is perfectly well known to steel manufacturers that at some of the principal works at home and abroad thoroughly sound steel castings can be cast by "dead melting" the steel, employing molds with a non-conducting lining, and running the ingots with a sufficient head, and it is a question how far the ingots so cast are inferior to those which have undergone compression. In other words, information is wanted as to the effect of compression on sound steel. If Sir Joseph Whitworth would run two ingots from the same melting of steel, subjecting one only to compression, and then test samples cut from the solid portions of both ingots, the comparative results would be of great interest, particularly if accompanied by further tests made of samples cut from the ingots, and subjected to forging. Such a series of tests would go far to show to what extent the admirable character of the material which Sir Joseph Whitworth is producing is due to the process of compression, or how far it is due to the careful selection of the materials from which the steel is made.

The whole question of the production of high class steel is, however, one on which much could be said, and it is, therefore, one on which it is undesirable to treat at the end of an article which has already grown to considerable length. We shall therefore, for the present dismiss the subject, but we propose to return to it, and to have something to say respecting other modes of treatment than that of compression in a fluid state.

Wooden Rails for Heavy Traffic.

The superintendent of the Muncy Creek, Penn., railroad, says the *Iron Age*, is about to try the experiment of laying wooden rails on that portion of the road between Hughesville and Tivoli, or two miles beyond. With a view to testing the feasibility of wooden rails, the superintendent recently had seven hundred feet of track laid on the curve just beyond Muncy creek, and to the surprise of all, it has been found to answer the purpose much better than was anticipated. The rails are of sugar maple, seven by four inches, and about twelve feet in length. The ties are laid down in the ordinary way, notched, and the rails "let into them" about four inches. They are then keyed firmly with wooden wedges driven on the sides, which makes the track very solid and firm. The locomotive and heavy cars have passed over this experimental track at different rates of speed, and it has been found to work admirably, and give every assurance of success. The cost of laying wooden rails, manufactured out of this hard material—that becomes almost as solid as bone when seasoned—is $450 per mile. Iron costs $4,000 per mile. No iron spikes are required, as the rails are secured with wooden wedges, and the cost of track laying is about the same as putting down iron. These wooden tracks have been tried at different places in the country, and invariably been found to work well.

The Bessemer Converting Process to be Improved.—The Bessemer metal process, in dispensing with the puddling process, and in utilizing the carbon, silica, and other combustible impurities contained in the pig-iron, to effect the fusion of the final metal, has given a vast extension to its application for railway bars, tires, boiler plates, etc. A drawback however to this method is, that it was thus far limited in its application to superior brands of pig-iron, containing much silicon and carbon and no sulphur or phosphorus, which latter impurities are so destructive to the desired qualities of the metal. Indeed, for such qualities of iron the puddling operation has still to be resorted to unless a new process is substituted, to purify those inferior pig irons which constitute the bulk of production; and this is the problem to be solved by iron masters, with the help of metallurgical chemists.

Rapidity of Steel Rail Manufacture.—As an evidence of the rapid progress which steel rail manufacture has made in America—a branch of industry of but very recent origin—the feat of making 1,010 steel rails in the space of twenty-four hours has just been accomplished at a rolling mill of Chicago. They were for the Chicago, Rock Island & Pacific railroad, of standard length, of sixty pounds to the yard, and of a total weight of over 268 tons. Eight furnaces were engaged in this achievement—the greatest accomplishment, it is claimed, ever done anywhere.

Ribless Boats.

Small boats, for coast and river fishing, "built up" without ribs, are very popular in Massachusetts bay, on account of their speed, lightness, cheapness, and ease of construction. They are so easily and quickly made that Eastern fishermen are becoming independent of the boat-builders, and each man builds his own boat at his leisure. To make one, the only materials needed are good clear pine boards, each the whole length of the intended boat, a few pounds of small nails (galvenized), and the materials for stem, keel and stern-post. The boards are run through a sawmill and cut into strips about an inch and a-half wide, and out of these the boat is built up according to working models. The models are merely patterns of wood that give the outside of a half-section of the boat. They give the shape of the boat at every foot of her length, and are formed from some existing boat or drawn from a scale designed by some competent boat-builder. The keel, stern-post and stem are set up and secured together firmly, and then to the keel two strips are fitted horizontally, one on each side, and having been planed down at each end to fit the model, holes are bored through them and they are securely nailed to the keel. Over each is laid another strip, and with the plane and shave it is fitted to them in such a way as to conform to the shape of the hoat, and then each is nailed down as before. In this simple manner the work proceeds. As the strips are nailed one over the other, they are bent to conform to the shape of the boat, and beveled to give the sides the right form.

A single day's practice in fitting the strips to the shape of the boat will enable a good carpenter to do the work with neatness and dispatch, and any person skillful with plane and hammer could in time turn boat-builder. When the sides rise to the gunwale, a broader and thicker strip of oak or ash is laid over all, to act as a fender and gunwale. During the whole process, the strips are kept heavily painted with white lead, and, when all is finished, we have a ribless shell, showing no nails except at the top, and exactly conforming on the outside and in to the model. To give lateral strength, shorter pieces of the strips are built up from the keel inside, and carefully fitted to the sides. The seats are placed over these, and then decks, store-room and cabin may be added as desired. Boats made in this way are very light and buoyant, and, being smooth on the outside, are good sailers. In case of injury they are easily repaired by cutting out the broken place and inserting new strips, secured by hacking on the inside. In practical use, such boats are found to be swift, dry and safe. They make good sea boats, and are said to resist injury with ease. In sailing they demand plenty of ballast, to compensate for their lightness. Their cheapness and ease of construction are rapidly bringing them into favor, as the cost is about one-third less than by the ordinary method. Two men with the material in hand can easily make a boat 18x6 in sixteen days.—*Scribner's World's Work.*

Reduction in the Weight of Cars.—Intimations are constantly coming from intelligent quarters that one of the fields of practical railway reform or improvement which is most neglected in this country relates to the reduction of the weight of freight cars or dead weight in transportation. The latest testimony bearing on this point comes from a prominent iron merchant of New York, who has recently visited England, and who has related to a reporter of the New York *Tribune* as one of his experiences that he "saw ore and coke arriving at furnaces on cars containing nine and a half tons of material, while the cars themselves were marked as weighing less than 13,000 pounds; on one road less than 12,000 pounds." Our own ten-ton cars weigh frequently 18,000 pounds. The saving of dead weight by the English plan seems well worthy of careful study by our railroads.

The Monster Gun Tested.—The secret testing of the monster gun at Woolwich arsenal, September 24th, sufficed to show that the great 81-ton gun is much the most powerful piece of artillery in the world. It is but a short time until it will be definitely settled whether vessels can be constructed in any manner to be invulnerable to the heavy projectiles of the future.. Six pounds were fired with quantities of powder varying from 170 to 240 lbs.; weight of projectile, 1,273 lbs. The pressure in the powder chamber varied from 22.2 to 29.6 tons to the square inch. The highest stroke force of the shot was estimated at 20,400-foot tons. The highest muzzle velocity of shot in sand bolt was 47 feet. The highest recoil of the gun up incline was 38 ft. 2 in. Bore of gun, 14½ inches.

Electric Light for Locomotives.—Russian railroad managers are experimenting with the electric light as a headlight for locomotives. Successful results were obtained on the line from Moscow to Kursk. The apparatus consisted of a battery connected with the front axle, the revolution of which set it in operation, and the track was illuminated a distance of 1,800 feet.

A New Motor has been invented by Chief Engineer Wood, of the United States navy, consisting of a power derived by the agency of carbonic acid obtained by means of electricity and galvanism. He has filed a caveat, and promises to exhibit his invention at the Centennial.

Sales at S. F. Stock Exchange.

The Mining Share Market.

The mining share market still remains in a very depressed condition, with low prices and few sales. The failure of the First National bank had very little effect on the market, but subsequent street rumors of the failure of prominent operators was a good thing for the "bears." The money pressure tells upon the market notwithstanding the prosperous outlook of the mines. The course adopted by the banks in relation to overdrafts keeps a check upon the stock movement for the present, until some new adaptation of means to wants is devised.

Among some a notion got abroad that the Con. Virginia dividend would be passed in consequence of the fire, but $9 per share was freely offered for the dividends payable next week, by the thousands of shares, or any part. There is no doubt about the payment of the amount, $10, and therein is manifested the extraordinary ability with which the mine has been managed exclusively in the interests of the stockholders.

There is really little of interest to mention in connection with the stock market. Several companies are having investigations or suits between stockholders and trustees, and so far, we are glad to say, the stockholders are ahead. We notice also a peculiar feature in an assessment levied on the Great Eastern Cons. quicksilver mining company, which has the following notice tacked on to the assessment:

Notice is hereby given that the directors of the Great Eastern Consolidated quicksilver mining company, at the same meeting at which the above assessment was levied, passed a resolution to give each stockholder one share of the company's working capital stock for every dollar of assessments paid in by each of them to the company.

Inducements of this character are so extremely rare that such a circumstance is worthy of mention. Our stock tables will show the state of the market during the past week.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

IONE HYDRAULIC M. CO.—Nov. 1. Location: Amador county, Cal. Capital stock, $1,000,000. Directors—B. Peart, Samuel Hart, David Goodman, J. D. Fry and Wm. A. Hooper.

MILLER G. M. CO.—Nov. 1. Location: Nevada county, Cal. Capital stock, $5,000,000. Trustees—S. W. Shaw, J. R. Gates, J. W. Wilber, John Miller and C. K. Robinson.

LEE G. M. CO.—Nov. 1. Location: Storey county, Nev. Trustees—J. M. Seamans, A. Heath, J. A. Harned, J. Treadwell and R. W. Hamilton.

CALIFORNIA FERTILIZING CO.—Nov. 1. Object: Manufacturing, using and selling fertilizers and fertilizing material, and especially that certain compound of animal matter known as a fertilizer of the soil, and claimed to have been invented by Gabriel Vidy; and for the purpose of buying the land and erecting and setting up buildings and apparatus required in the manufacture of fertilizers. It is provided that the capital stock shall be unassessable, and to consist of $10,000,000, to be divided into 100,000 shares. Directors—A. P. Hotaling, P. von Loesecke, Isidore Landaberger, Edward M. Gallagher, Charles Kohler, Henry A. Cobb, Thos. Noble, W. K. Dietrich and J. S. Rosenbaum.

AMERICAN M. CO.—Nov. 4. Location: Storey county, Nev. Capital stock, $10,000,000. Directors—W. J. Conolly, Aaron Holmes, E. A. McCloud, Thos. Wallace and Richard B. Noyes.

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in the Mining and Scientific Press and other S. F. Journals.]

on. There is now no room to doabt the greet richneea of this mine.

At the Sliger mine, near Spenish dry diggins, the lucky hut reticent owners heve heea qaietly taking ont a large amount of extraordinary rich ore for sevsral months. From all we have bsen ahle to learn, we douht whether any mine on ths Pacific coaet has yielded better or ss wsll, in proportion to the amount of work dons nnd the qnantity of rock crushed.

At the Taylor mins, near Greenwood, dsvelopments on the pay chute have been extended since our last notice, nntil it is now dsmonstrated that it extends more than 250 feet. Old and experienced miners declare this to be the longest single pey chute ever developed in California. It embraces a lerge mase of vein matter of very even average as to yisld, and which can he extracted and crushed with remsrkable eese at low cost. With proper machiaery, and with less force than is now employsd at a profit, more than three times the ore could be extracted and crnshed than nt present. Inasmnch as the mine ia more than paying expenses, with three times the yield, at actually lesa expense, the profits and dividends would he enormous.

At the Rosenkranz mine, Superintendent Burlingham is still driving ahead with accustomed energy, and ls taking out conaiderable quantities of very high grade ore. At the Woodaide mine, the difficultiea about ventilation have heen overcome and they are taking out rich rock and realizing fine returns.

INYO.

The Cenao Gordo Goln Find.—Inyo *Independent*, Oct. 28: Some two weeks since we made mention of rather an exciting discovery of gold on the dumps of aome silver-lead minee of Cerro Gordo. Since then we have aeen a very fine specimen of about three ounces weight, being quartz and gold in nearly equal proportiona. It is found in quartz boulders of nearly uniform shape, hut of all aizes. The boulders containing the gold are heavily coated with iron rust or something of that nature, so mnch so that no metal had heen seen or suspected to exiat in the quartz until some months since, when some Mexicans working the lead mine by oontract happened to hreak a rich piece exposing the gold. The discovery was kept secret for a long time, it seems, at least so far as the owners of the mine, Belshaw & Oo., were concerned. In that period the Mexicans, it is aaid, managed to get away with about $3,000 of the richer specimens.

KERN.

Consolidaten Bunnel.—Bakerafield *Gazette*, Oct. 30: Oolonel Burr arrived a few days ago from Keruville, bringing some heantiful specimena from the Conaolidated Bunnel mine. The discovery claim of thia mine, where work is heing dono, is a few miles north of the town, hut it haa been traced south nntil opposite on the west. The company claim 12,000 ft, all of which, it is said, crop out oontinuously. The prospecting work done consists of a tnnnel 150 ft in length, from the point of beginning to the oasing of the lead, reaching it at a depth of 101 ft. Acrosa this a tunnel has heen extended, and it ia found to oonaist of 22 ft of metalliferoua veln matter, 7 ft of which is pure, hard quartz, very rich in hoth silver and gold, and assaying up into the thousands. It is milling ore, the silver appearing in the form of chlorides, sulphurets, raby silver, and in the state in which it ia more or less known to everyhody efter hecoming a medium of exchange. A mill is in contemplation, and a town has heen laid out, to he oalled Ruby city.

NEVADA.

Californta Mine.—Nevada *Transcript*, Oct. 30: The rock in the California mine, on the soath aide of Deer creek, is now looking first rate and is paying well. That part of the ledge on the north aide of the creek, known as the Gold tunnel, will soon he ready to he worked throngh the new inoline. The shaft will he 600 feet from the preaent one, which is on the banks of the creek. It is 600 feet deep, and will he oompleted next week. The hoisting works will then he moved there as soon as possible. The mine has heen worked at that point before and very rich rock was taken out. It is expected it will continue to afford better rock than has heen found sonth of it. The ahaft ia said to he a very fine piece of work. The mill will he left where it is now, so as to be run with water nntil next spring, when it will be removed up to the new shaft and he run with steam. The returns of the California mine will soon be sufficient to pay splendid dividends, nnleas all aigns fail.

Providence Mine.—The owners of the Providence mine have, aince July, been performing lsad work most of the time in the hest part of heir mine. They have opened up new levels, tripped the ledge and left the rock ready to he aken to the aurface when the proper time omes. Enough rock has heen taken ont of ther parts of the mine to keep the mill runing, but the "honanza" portion ia awaiting he completion of Fryer's works. A mining exsrt from San Franciaco, after examining another mine upon which he is to report, visited nd passed through the Providence laat week. Ve are informed that he saya he never saw s pretty a sight in all the mines he ever vised. The rock which lies exposed, ready to be aken ont, ia rich in sulphureta and galena, and glistens like fire aa the lights shine upon it. he dsposit ia very large, and by mill process ill pay up into the hundreda. It is intended work it all by the Fryer process.

Gold Bars.—Grass Valley *Union*, Nov. 3: he Empire mine, the oldest working mine now in this district, ls doing well. We say so because we saw yesterday two very heavy and handsome bricks of gold that had just oome out of the mine. We do not know what the veine of those hricks were, as we could not find Mr. David Watt, the superintendsnt, nor James Bennalleck, the foremen, nor yst Mr. Provines, the amalgamator, to inquire. We "hefted" the hars snd thought that about $18,000 worth of gold wae contaiaed in them.

PLACER.

Mining Interests.—Plecer *Herald*, Oct. 30: What amount the gold yield of Plecer footed up in the halmy days of its existence we have no immediate means of knowing; but we confidently believe that, should the aesson prove favorable, there will he more gold extracted from the minee in this coanty in the succeeding 12 months than was ever taken ont during the sams space of time in the past. Our quartz mines are producing more gold per month than they sver produced bsfore, with the indications favoring still better results. Passing hy the extensive hydranlio works recently opened near Anhurn, now runuing in full hlast with indications of very flattering reanlts, we find that the main ditches supplying Michigan Bluff, Bath and other towns on the Forest Hill divide have, during the summer, bsen greatly enlarged an improved, with the view of a corresponding enlargement in the mining enterpriaes of that aection, a reault for which preparations are heing made, and which, therefore, it is not unreasonahle to expect. Again, we find on the Iowa Hill divide the great Iowa Hill canal ao nearly completed aa to afford this coming season a large amount of water, all of which will be applied to the heat practical advaatage in the deep and extenaive gravel mines in that section; mines known to he rich, but not previously worksd for want of water.

SHASTA.

Coal Mines of Shasta.—Shasta *Courier*, Oct. 30: Years ago ooal was discoversd on the headwaters of Clover creek, and specimens of the same were tried in several hlacksmith shops and prononnced good coal. At that time there were ao roads leading to the locality where the discovery was made, and, as in those daya "gold" waa all the go, hat little attention was paid to the coal bed. But times have changed, and coal is now considered a "good thing," and commands gold. The developmenta in Peck & Kincaid's coal claim, and the great attention it has recently attracted from capitalists and owners of large manufacturing establishments helow, has led to the re-examination of the "original discovery" coal mine of the county, and to looation of claima thereon. Christian Hick, a native of Pottsville, Pa., and a man now 88 years old, having heard of the great value aet upon the Peck & Kincaid mine, and having examined apeoimens of the coal taken therefrom, said he knew the point where the "first coal was discovered in Shasta coanty," and went and found the place, and he and his frienda have located claims and applied to the Governmeut for title to 1,920 acres of land covering the main coal belt as far as discovered, bnt its full extenaion is not known. A nnmber of workmen are now engaged in opening the ledge, which now shows a face of lignite coal, of fine quality, six feet in thickness.

SIERRA.

Iowa Company.—*Mountain Messenger*, Oct. 30: The Iowa company hroke their pump ahout ten daya ago, and have not heen progressing as fast as they would had the acoident not occurred. They sent immediately to San Francisoo for a large pump and it is prohably in plaoe by this time. The old pump was six-inoh, the new one is eight-inch and of ample capacity to prevent the worka from ever heing tronhlsd with water. The oompany have a sump ahont thirty feet deep, nnd will soon commence opening the mine and taking out pay.

Forest City.—Thia little hnt enterprising mining hurg atill holds its own with hright prospects of a hrilliant future. The dumpa of the Bald Mountain company are nearly full, and if rain don't come in a hurry, work will necessarily cease until the reservoirs are filled for a wash up. Everyhody is praying for rain—the minera, to nnearth the glittering gold; the ladies, to free the atmosphere from dust and smoke; the long-suff-ring teamsters, to allay the dust on the road; and the rest of humanity on general prinoiples—that nothing is worse than "too much of a good thing."

The mining companies are husy, steadily pushing forward operations. The North Fork Co. are ahont to sink a shaft, and will he oompelled to run on assessments a while longer before declaring dividends. The South Fork boys are still energetioally cutting away into the bosom of the mountain.

Relocating.—We are informed that partiea who owned mining claims at Monte Cristo fifteen years ago, are now coming hack to claim their ground, other parties having since opened claims and discovered pay. Who the parties so attempting to claim ground ahandoned are, we do not know; but we do know that any such attempt ia a fraud on the present owners, who took up the ground supposed to be worked out, and expended money and time developing it. It is the meanest kind of frand, too, for some buffer, aa soon as he hears that somebody haa struck pay in ground he once owned to oome along and bring suit to recover; and the law is a fraud that will permit him to bring suit without compelling him to give indemnifying bonds to make good the present owners who may be compelled to spend a large amount of money to protect their property from the assaults of the above mentioned kind of cattle.

Nevada.

WASHOE DISTRICT.

Consolidated Virginia.—Gold Hill *News*, Oct. 27: On Saturday last a strong flow of weter hroke throngh the east wall of the mine on the 1400-ft lsvel, flooding the 1500-ft etation and stopping all extraction of ore for the time being. By energstic and judicious managsment the watsr was got wsll undsr control hy Tuesday last, when, in an hear'e time, ths hoisting works, mschine shops, a million and a quarter feet of lnmhsr and timhsrs, 800 cords of wood, the splendid 60-stamp mill, in fact evsrything on the surface of the grounde, were reduced hy fire to a mass of smouldering ruins.

Ophir.—The morning after ths fire msn were set at work to clsar away ths dshris, preparatory to rshailding. Everything will be set going ngain as soon as mechinsry and building materiel can bs obtained.

Rock Islann.—Driving the main west drift at the 650-ft station, to cut ths ledgs, is going slowly forward, the flow of watsr from ths facs heing qnite atrong. Sinking the winze below the 450 ft level ia also making good progress. No changes during the week.

Justice.—The face of the cross-cut at the 600-ft level in the old south mine, or Waller Defeat section, continues in excellsnt ore, and the drift south from the main Justice shaft, at the 800-ft level, ia in very favoraole vein matter, with streaks of low grade ore.

Julia.—The good prospecte opened on the 1400-ft level are steadily on the increaae, every foot of the drift on the 1400-ft level run, adding daily to the valne of the developmenta already made. The ore prospects in the hottom of tho shaft are also growing more encouraging every day. The developments in the face of the main south drift on the 1000-ft level are very encouraging.

Belcher.—The ore hreasts all continue to hoth look well and yield finely. The flow of water in the main incline still continues quite strong and is ahont all the pumps can handle. The 1600-ft level drift ia heing thoroughly retimbered, which will he finished in a very few days more, ready to reanme work in the face of the proapecting drifts. The up-raise from the 1400-ft level ia nearly connected with the winze below the air ahaft on the 1300-ft level, which will give a thorough ventilation of the mine to that depth.

Lany Bryan.—Sinking the main ahaft is making good headway. The aonthwest drift on the 170-ft level has encountered a mixture of clay and quartz, the quartz oarrying ore and being of a very encouraging charaoter.

Globe Consolidaten.—The ledge was struck on last Friday in the main adit tunnel, and penetrated a diatance of eight or ten feet. A portion of the ledge at the point where it waa atrnck, ia fine quartz, filled with sulphurets, and a portion ia qnartz and clay mixed with porphyry. Taken altogether the prospects are qnite encouraging.

Hale & Noncaoss.—Prospecting the 2100 ft level is still vigoronaly prosecnted. The south winze on the 2200-ft level, is down forty-eight feet, the hottom in a mixture of quartz, clay and porphyry.

Amazon and Glasoow.—The main shaft ia sunk to a depth of fifty feet helow the seoond station and 354 feet helow the oroppings. The ore at the different stationa ia showing a steady improvement as greater depth is attained, ao that the prospects of hoth mines are greatly on the increase, the ore assay daily growing better.

Woonville Consolidaten.—The main drift ou the 420-ft level is in a distance of 60 feet, having made excellent progresa dnring the week. The new pnmping machine is on the ground ready for erection as soon as the heavy atone foundations are completed, whioh will he in ahoot a week more.

Lady Washinoton.—The powerful new machinery, which, as we have heretofore stated, is a duplicate of that at the famoas C. & C. shaft, was startsd up for the firat time to-day, and operates fully aa well aa was anticipated. The hig new Cornish lift pump is raising the water from the ahaft at a lively rate.

Leo.—Work progressing favorahly as usual. Face of drift from the hottom of the incline winze continnes in very favorahle vein matter carrying good indications.

Imperial-Empiae.—Daily yield 40 tons of ore, which ia moatly extracted from the ore hreasts hetween the 1850 and 2000-ft levels. The ore stopes are all looking well.

North Chipman—The shaft is completed and thoroughly timbered to a depth of 100 feet. It is ao far one of the finest working shafts on the line of the Comstock.

Orioinal Goln Hill.—Face of north drift in low grade ore. South ore hody ahowing continued improvement as further developed. Preparations heing made to extract ore for milling.

Sutao.—The main west tunnel is steadily advancing, the face in much aofter ground than heretofore. A alight increase in the flow of water.

Succor.—The west and north drifts on the 550-ft level are steadily pressing forward.

Cosmopolitan.—Considerable improvement in the face of the main tnnnel; yielding an increased amount of good pay ore.

Sullivan.—New ahaft 72 ft deep. Drift in 112 ft. Both shaft and drift in the same very promising vein matter mentioned heretofore. It is the regular Comstock ore vein formatiou and streaks of it give good aseaya. The shaft being at the oaat aide and the drift on the west, thia fine vein is kuown to he at least 150 ft wide. It is a really important development.

Oveaman.—The pumps once more have the water undar complete control, and work hse been resumed in the main west drift on the 1100-ft level.

Sierra Nevada.—Sinking the msin shaft ie going rspidly ahead, the hottom in good sinking ground. Ths main west drift on the 1000-ft level is hsing drivsn steadily forward toward ths ore vein. Good progress is heing made.

Florida.—The pumping machinery is doing splendid work, and keeps the shaft frss from wstsr with perfect ease. The flow from the face of the west drift is on the decrease, and the direction of the drift is changed to the northwest in order to cross-cut ths ledge soonsr, being more at right angles. Very good aeseys continus to bs ohtained.

Chollar-Potosi.—Daily yisld, 50 toas of ore, the sseay valns of which is $31 per ton.

North Consolidaten Viaoinia.—Sinking the main shaft is making splendid headway, the rock in the hottom bsing a little firmer than herstofore, hut hlasting well.

Baltimore ann American Flat.—A small amount of rich ore is heing daily taken from the 450-ft statioa.

Leviathan.—The fine ore development at the 420-ft level continnes. Present indications go to show that this ore helongs to the same vein as that developed on the level ahove, end that the hody is continuona from one level to the other.

New York Consolidaten.—The new machinery continues to work as smoothly and well aa could he desired, and at the rate it is lowering the water in the ahaft, the bottom will be reached hefore our next weekly report.

Calenonia.—Sinking the shaft is making good headway.

Nevada.—Sinking the winze helow the level of the east oross-cut from the main aonth drift, on the lower tunnel level, is making excellent progress—the hottom in lively, fine-appearing quartz and ore.

Europa.—Sinking the main shaft is being presaed with all the vigor possihle.

Paospect.—The rock at the bottom of the shaft works favorahly, allowing of good progress in sinking.

Silver Hill.—The main east drift at the 4th station level ia steadily advancing, the face in favorahle working ground. A slight hody of water is met, with indications of a considerahle hody ahead.

Bullion.—The main north drift on the 1700-ft level is rapidly advancing along the west wall of the ledge, with steadily increasing prospects.

Mint.—Sinking the shaft is going steadily ahead, the hottom still in soft working ground.

Sutao Tunnel.—Total length of tunnel to-day, 11,250 ft. The face of the headsr is now in a hard streak of porphyry.

Colorado.

Chelsea Beach.—Colorado *Miner*, Oct. 30: A short distance helow the Brown mine, in the gulch that is noted for the workinga of the Brown, Terrible, Seven-Thirty, Hercules, Roe, Mammoth, Glaagow, and many other large minea, J. McDonald and othera have heen working for a year pnat on a lode called Chelsea Beach. The present developments are a shaft 75 ft deep, with levels at the depth of 35 and 70 ft. The crevice ia of the uniform width of three feet and carries an average vein of ore four inches wide, milling 995 to 117 ounces per ton. The ore is ohiefly galena, intermingled with zinc blende, and often hears heantiful streaks of ruhy and gray copper. Ahont $10,000 has been taken from these workinga, and as much more is in sight. Five drills are running, and more will soon be added. The hoys are tolernhly sure that they have a first-olass mine, and would as soon keep on working it as to devote their spare time to clipping the coupons off U. S. honds.

General News Items.

The Salt Lake *Tribune* says: "It may be of interest to a large numher of yonng gentlemen and ladies in this city, jnst now, to know that there is no marriage law in the Territory. Simply standing up in the presenoe of yonr mother-in-law and saying: 'Sal, let'a hitoh,' or, 'Jerusha, let's go pards for life,' constitntes a legal marriage, and don't cost a cent."

Not less than $300,000 worth of oysters will be sold from Shoalwater hay beds this season, the gathering and moving of them forming one of the chief industriea of Washington Territory.

A Young man named John Rohinson, a consnmptive, on his way from California to his home in Michigan, died on the train near Laramie a few days ago.

The London *Standard's* Santander special says Generals Lama and Quesada have captured Ordnne.

Some fine looking cinnahar has recently heeu found about five milea west of Huffaker's, in Washoe county, Nevada. The locality has not been prospected to any great extent, excavations to the depth of n few feet only having been made.

The mines without exception in Winnemucca mountain are paying the workers of them handsomely for their tronble in extracting the precious ores. There are quite a number of good claims lying idle upon the hill at preaent.

The striking of rich gold quartz in aome of the old mines in Hnmholdt district, Nevada, near the Humboldt houae, has created considerable excitement in that vicinity; so much so as to cause a reorganization of the district.

Amber.

Amber is formed by the pith (medulls, or marrow) which flows from trees of the pine species, as gum flows from the cherry trees and resin from pines. It is, first of all, a liquid which bursts forth in abnudance; then it is congesled by the cold, or by the heat, or by the sea, when the great tides rise and sweep it from the islends. At all events, it is thrown on the cossts, snd it seems to swim with the waves, and not go to the bottom. Our snoestors, thinking that it wes the sep (succns) of a tree, called it, on that sccount, succinum. What proves thet amber is the product of a species of pine, is that when ruhbed it exhales an odor like that of the pine, end that when set on fire it burns efter the fashion, and with the scent of a resinous torch. It is conveyed by the Germans into Pannonia (Hungary) chiefly; thence the Veneti (Venetians), whom the Greeks called Heneti, who are in the immediate p ox-imity to Pennonia, and who lived round the Adrietic see, heve brought it into vogue. The feble which has connected the Padus with amber has an evident cause. In our own dey, the Trsnspsdanien peasant women wear an amber neoklace, for the sske of ornament, no doubt, but also a remedy, forasmnch as amber is deemed good for effections of the tousils and the fauces, these and the neighboring parte of the body heing snbject to meladies produced by the different kinds of waters in the neighborhood of the Alps. From Csrnuntum, in Pannonie, to the coast of Germany, whence amber is brought, there are six hundred miles, a fect not known till recently. Still lives the Roman knight who wss sent to procure amher by Julianus, superintendent of the gladiatory games given by the Emperor Nero. This knight traveled over the markets and the shores of the country, and brought back such an immense quentity of ember thet the nets intended to protect the podium from the wild hessts were festened with buttons of amher. Adorned likewise, with amber, were the arms, the biers, and the whole spparatus for e day. The largest piece the knight hronght weighed thirteen pounds. It is certein tbat amber is also a growth of India. Archeleus, who reigned in Cappadocie, stetes that from that country (India) amber is brought in the crnde stete, end still edhering to the pine berk. It is polished by being sodden in the fat of a sucking pig. Whst proves thet the amber first flowe es a liquid is thet owing to its transparency different ohjects may be seen in the interior, such es ants, small flies, and lizards. It is menifest that those objects got entengled in the ember when it wes still in the liquid stete, and thet they remained imprisoned when the ember hardened.

There ere msny kinds of amber; the white is thet which has the sweetest ecent; hut neither the white or the uncolored are worn much. The deep yellow (fulvns, tawny, fallow) is the most esteemed. Thongh the trensperency of the deep yellow amber is a recommendation, intense brilliancy is objectionable. To please there must be present, not fire, but the resemblance of fire. The amber most in request is the Falernian wine. It is transperent, and has a softened splendor. Certain kiuds attract hy a tender shade, like the tint of hoiled honey, but it ought to be known that any color oan he given to amher that is thought fit. A particuler dye can be given to it by meens of kid fat, or of the anchnsa root; it cen even be made to teke a purple tinge. Moreover, when, hy being rubhed in the hsnd, amher is enriched with an animating heat, it attrects etrew, dry leaves, hest, just as the loadstone attrects iron. Bits of amber in oil will burn with a hrighter and more enduring flame than wicks of flax tow. Suoh is tbe excessive commercial value of thie substence, thet a small humen effigy in amber is sold for a higher price than living and vigorous mon. Verily, one censure (of auch folly) ie not enough. In the objects called Corinthian, copper mixed with silver and gold pleeses; in cerved objects, the skill end genius of the artist delight. We have shown whet recommends murrhines and crystals. Pearls are worn in the ears; gems on the fingers. In short, in ell foolish superfluities there is either the satisfaction of vanity or there is reel use; bnt as regards amber, there is nothing to charm beyond the consciousness of possessing an erticle of luxury. Domitus Nero (the emperor), along with his numerous other ebsurdities, had given the name of ember to the hair of his wife, Poppœs, and he had even celebrated the heir es amber in eome verses; for fine names are never lacking for corporel defects. From thet moment ember became a third color, much in request with the (Romau) ladies. Amber, however, is found to be of some value in medicine; but this is not the reason why women are fond of it. Worn as an emulet, amber is advantageous. According to Callistratus, whether teken in a drink or worn as an amulet, amber at all ages ie medicinal in cases of madness and dysuria. This writer mentions a fresh variety, which is called chryselectrum, and which is (as its name indicates) of the color of gold, and in the morning presents the most charming gradistione of hue. For fire it has a signal hunger, and if it is near fire it catches flamo and burns with immenso celerity. This amber (if we may believo Callistratus) cures fever and other dieeases, if it is worn on the nock; cures affections of the ear when it is ground and mixed with honey and oil of roses; cures dimuess of sight when mixed with Attic honey; cures affections of tho stomach, either when taken in a powder alone, or drank in water along with a mastic. Moreover, amber can be efficiently and extensively employed in imitating translucid precious stones, especially amethysts; for, as we have seid it can be tinged of every color. The pertinacity of certain enthors forces us to spesk, next of all, of lyncurium; for those who do not meintain thet this is a kind of amber, yet, at leest, declare that it is a precious stone. They effirm thet the lyncurium is the product of the urine of the lynx, bnt blended with a kind of eerth; this animsl (so the authors ssy) covering up his urine as if grudging the benefit men might derive from it; thet it has the same tint as the fire-colored amber, end cen be carved; that it attracts not only leaves and straws, but thin plates of hrsss and iron, which Theophrastus, giving credence to the statements of Diocles, believed.—*Cope's Tobacco Plant.*

Phylloxera in California.

A fow notes of a flying trip I lstely made to Sonoma, may he of interest to your readers. My main object was to become acqusinted with the local features in their hearing upon the ravages of the Phylloxera or vine louse, which heve of late become so serioua es to alerm even those who, not long ago, were wont to make sport both of the insect and of its discoverers.

The Napa valley seems, thus fer, to be almost exempt from the pest, although some unpleasant symptoms are reported from several localities. I did not stop to examine these, the more as the Napa vitioultural society eppeers to he fully alive to the danger, and its active secretary, Col. Eyre, is vigorously sounding the alarm through the newspaper press.

The hillside vineyards, seen on tho stage route to Sonome, look well; but as we approach the town, sickly spots are seen here snd there, and hecome quite frequent and obvious as we proceed beyond, on tho Santa Rosa road. While some of theee, forming conspicuous depresetone in the luxuriant mass of folisge, are evidently the work of the destroyer, whom good culture alone cennot keep in check, there are others which speak only of shallow or insufficient tillage, want of drainage or neglect. Still, meking due allowance for such cases, there is enough of the real article to justify the most serious apprehensions for the future, unless the progress of the evil is promptly checked.

The region most sorely afflicted thus far, is the Wohler neighhorhood, ahout four miles beyond Sonoma. Here some ten acres of vines, over ten years old, etand dead or dying, and much of whet remains is fearfully pitted with the ominous deed spots, speeking of new centers of destruction. But if you dig or pull up one of the ssd looking specimens in search of the enemy, you will be disappointed. The phylloxera is fond of good living, and leaves its depleted victims for "fresh fields, and pastures new," some time hefore one uot acquainted with the peculiarities of the plegue would think the csse a hopeless one. You will, perhaps, find a tew main roots still alive, but their outer bark is loose around them, end heneath is a blackish, spongy powder. Here and there, perhsps, a solitery straggler may still he seen. But go the next fair looking vine—with its crop of herries just e shade less mature and full than they ought to be—hare the crown of the root, end you will see the surfece diversified with yellowish spots, which any good eye, but still better, a magnifying gless, soon resolves into scores of shield-shaped, cross-wrinkled insects, of a great veriety of sizes, from a mere dot to about one-fortieth of an inch. Intermingled with these ere clusters of oblong yellow eggs, a copious supply of which may he found in every crevice of the berk. The lice cannot he said to "swerm," for they sit perfectly still, with their thread-like hoak (almost the length of the entire hody) aunk into the substance of the sap-wood. Occasionelly you see one standing on its head, struggling end kicking viciously, in the effort to get a hetter lodgement—absurdly like a hog rooting for potatoes!

Go a few rows further into the apparently healthy vines in full bearing. You mey see nothing about the stock or principal roots; but dig up some of the fine terminel rootlets which interlace from both sidee hetween the rows, end you may find them teeming with lice. They are the scouts and outposts of the advancing army, which can thus ohviously cross from row to row underground—a fact which explains the limited efficacy, or often total uselessness, of any ohstacles to their progress eplied around the stock or crown of their roots. And since, moreover, Riley has shown that the winglese insect can migrate with tolereble ease over the surface of any ordinary soil, the hope of thus checking its spread must be abandoned.

Beyond the tocus of greatest inteneity, just referred to, we find the splendid vineyards of Hon. McPherson Hill, Gen. Whalen, Ches. V. Stusrt and all others further up the valley, as yet exempt from attack, so far ae known.

Such is the state of affairs at this time. What it may be a year hence, unless vigorous measures are at once taken, may be inferred from the fact that in one spot where a dozen vines were affected last yoer, some *seven hundred*—almost an acre—are now gone heyond hope of recovery.

Now, as to the means of prevention and cure. I doubt that we can do better than follow the lead of the French Commission, availing ourselves of the dearly hought experience of the European viticulturists; the more as we are cultivsting the European grape, which with us is affected precisely as in Europe. The insect attacks the roots exclusively; not a leaf-gall is to be seen. Hence it is probeble thet the winged form is rarely developed; as yet, it has not been seen at all in Sonoma.

The French Commission finds that the use of weak solutions of alkaline sulpho-cerhonetes for the destructiou of the vine-louse, aided by that of potassic and ammoniacal manures for strengthening the vine, insures, if not the extermineticn of the insect, at least certsiuly such relief as will meke the vines to bear profiteble crops. And they add that where these means have failed of succoss, the failure is directly traceable to injudicious or imperfect use.

I think wo should attach great importence to a formel expression of opinion coming from such men as MM. Dumas and Cornu, despite many contradictory reports from private sources. It is well known that of all experiments, those in agriculture require the ntmost circumspection in their execution. If the remedies prescribed for vines recently attacked have failed to resuscitete dying ones; if a slovenly or niggerdly application hes left the evil apparently unchecked, there are but too msny who will at once reise, end many more who will echo, the howl of uusuccess.

Let us, as quickly as possible, give the prescription of the French Commission a thorough triel, while diligently searching for further remedies. Should private enterprise fail to furnish promptly the needed supply of the sulpho-carhonates, the agricultural and chemical departments of the University are willing to take the matter in hand, if means ere furnished. I am now engsged in the investigation of the soils of Sonoma valley, with a view to determining in what manner the enriching process mey most cheaply be carried out. Direct experiments on vines cannot usefully be made on the agricultural grounds at Berkoloy for obvious reasons; but all possible assistance will be given to individuals and socicties willing to experiment on the spot.

I cannot conclude without strenously recommending, in the planting of new vineyards, a trial of the retional expedient already largely practiced in France, of grafting the European grapes on American roots, which strongly resist the vine-louse. Among these, tho Clinton and Concord seem to he especially worth trying. But local experience must definitely settle the hest stock for grefting, which evidently varies in different localities. Experiments on this subject should immediately be initieted hy the viticultural societies of tho State.—*Prof. Eugene Hilgard in Rural Press.*

The Winter Here and at The East.

There is none of the darkor shades of human nature that is more conspicuously brought torth hy those who expatiate on man's depravity than ingratitude. Now, for our part, we could nevor see the difference in culpability hetween slandering an individual membor of the human family, accnsing him of had habits to which he is really not addicted, and "lumping" the whole rece together, and charging it with crimes and misdemeanors of which it is not guilty. Prominent smong which is ingratitude; it has secured this pre-eminence, no doubt, from the fect thet it is concedod to be the worst thing that its detrectors can say against human nature, ingratitude being supposed to be coneiderably sharper than a serpent's tooth. These poets ero hlind guidee, and the world has suffered immensely, end done itself great injustice in judging human nature by e poetical estimate.

Men is not ungrateful. Let those who wish to see proof of his gratitude in small things place some little favors in bis wey, and watch nnprejudiced the effect upon the recipient. Let them suepend for a moment their supposed commendable efforts at making two blades of grass grow where only one grew beforo, and make an attempt on the soil of the human heert to produce a few more fresh, green blades of gratitude, and they will soon behold satisfactory results; or, if an exhibition of the higher reaches of gratitude ie desired, the best way to form a correct estimate of the feelings that prevail in men's intercourse with hie Maker is to note the manner in which he receives what the seasons hring in their coursee. It is hardly feir to call it local pride, when the Arab, after duly enjoying "the spicy breezes" and ell the other glories of "Araby, the blest," throwe himself upon the sand, and after the dread simoon has passed over his proetrate body rises up end exclaime, "Alla is good." Or the inhahitant of more rigid climes, who, in a similer manner, megnifies the blessings of *his* country, manifests a degree of gratitnde which is worthy of notice in a race which has been represented as quite destitute of this quality.

If the climete of California disinclined to labor and were enervating in its effects, we should have slight grounds for rejoicing; hut instead of this, we have an atmosphere hy day stimulating to labor or active exercise, aud at night everything favore sleep. These qualities are doing much towerd stimulating immigration hithor; and we shall look for little cessation in thie flood through the winter months. The season's reports from thoso who are spending their first winter here will also induce immigratiou. Taking these matters into consideration, we shall look for as great an influx in the early part of 1876 as wo received in 1875, notwithstanding times havo somewhat improved thero, and though all possible influences aro being used to keep people

The Crystal Salt Works.

The Alameda County *Independent* ssys: A visit to the Crystel salt works, near Alvarsdo, this week, hes enabled us to gather a few items of interest to our readers concerniug the msnufacture of this article. Some time since we gave an accouut of Quigley's sslt works, and then declered our purpose, as soon as possible, to gain and give further information about other salt works in our county.

These Orystal selt works were first started in the year 1864, by J. A. Plummer. Only three hundred tons were mede thet year, as the whole matter was new, and the experiment e venture for the owner. In 1865 the labor began iu reel esrnest, improvements were established, and the enterprise began tc assume sll the charecteristics of a permanent and profitsble undertaking. Since that year the manufacture has been steadily advanciug in activity and success, until it now stands equal and probably superior, to any salt mannfactory on the hay.

The present year not less than 2,000 tons of choice packing salt will be manufectured hy this establishment, end this kind of salt meets with ready sale among the heef and pork packers of San Francisco end elsewhere.

There are two separate branches of this enterprise, one under the chsrge of J. A. Plummer, Jr., and one under ths direction of C. A. Plummer; while the general husiness is msnaged in San Francisco by J. A. Plnmmer, Sr.

The quantity of salt required for family use is far beyond what those unacquainted with the business would anticipate. Thus, this establishment griuds twenty-four tons of table salt, twenty-five tons of deiry salt, and fifty tons of pork-packing salt weekly; and a double gang of men is employed, so that the work may go on hy night es woll as by day in the mill and drying-house. A steam engine and regular dryers are connected with tho works. The salt is put into large bags when grouud, snd shipped to the packing-house in San Francisco, where it is repacked in small sacks, and haled for market.

There are nine vets, all huilt of Oregon pine, in the brsnch under J. A. Plummer, Jr. Only lumber is used, and thst of the hest kind, there being no eerth divisions between these vats, and for them no less than 150,000 feet of the above lumber were fouud necessary. There are six warehouses for storing the salt, aud s tramwey connects them with the landing, where there ie also a large storehouse as well as cosl sheds.

Tho branch establisbment, under Charles A. Plummer, is called the Turks' Island salt works, snd is situated ebout a mile directly west of the town of Alvarado. Here there sre five vats, which have also turned out this season 1,000 tons of choice rock salt. These vats, too, ere built exclusively of Oregon pine, which experience shows to he the best material for the purpose. A tramway connects these works also with tho landing, rnnning a distance of ahout 1,500 feet. Only pork-packing salt is ground here, and 300 tons have been ground thus fir this season. A schooner of fifty-five tons burden belongs to the company, and is kept constantly ruuniug to San Francisco to trausport the salt from hoth of these brsnches. These latter salt works were first started by Plummer & Sons, in 1868.

Thirty men are kept constently et work during the husy season, that is, the salt making season, which is during the hot end dry weather. Wooden and steel hoes are used to rake up the salt, which is first drawn into windrows, then into piles and in straight rows. A portable track is laid down hetween the piles, upon which the cer is placed, and tho salt put into it and then run down to the shore, where it is washed end stored. In washing, ammonis, nitric acid and lime-juice are employed, after which the salt is considered ready for use in the market, or for sale. To show the purity of the article, as here manufactnred, we may meation thet the State chemist analyzed it, sud found thet the salt stood et ninety-seven per cent., or only three per cent. below ebsolute perfection or free from the admixture of all foreign substences.

Truly these salt works furnish ebuudant evidence of what an important and extensive industry hes grown up along our bay shore from very small beginnings—an industry that is still further cepeble of almost indefinite expansion and enlergement.

PRODUCTS FROM DISTILLATION OF COAL.—The burning of a piece of bituminoue coal seems, and really is, a very simple matter; but to nnderstand fully the chemistry of the process is a matter requiring much thought and study. Observations thus far have shown thst such combustion results in the formstion of at least fifty-one different chemical compounds, to say nothing of the indefinite number not yet determined, and which aro supposod to be quite numeroue. There is a practical utility in knowing these compounds, as without thst knowledge it is impossible to calculate accurately the heating power of any given coal.

A WRITER in a Belgian journal says thst be has snccessfully kept a marine aquerium for nearly ten years without renewing the ees wster in it; all that he does heing to edd fresh water as tho salt water evaporates, the same degree of saltness being invariably maintained.

MERCURIAL ointment is excellent to oil a gun with to prevent rusting. It is also equally good applied to cutlery, needles, or other polished

Good Health.

How Small-pox is Communicated.

Small-pox originates from actual contact with the developed scab, from this scab dissolved in water, or from the effluvia of it. It is not communicated by the *developing* vesicle or pustule, or received from being in a room or car with a person with the eruptive stage *commencing*. In all cases the disease is caused by the well-developed scab or the matter from it. The following cases will illustrate the truth of these assertions:

1. A young man came to the country from New York city, riding in a railroad car forty miles and in a private carriage six miles. The evening of his arrival I saw him. He was complaining of headache, and thought he had a "bilious" attack. The third day he had a severe sore throat, and upon examination I found a vesicle upon the end of the uvula. He complained too of his back, and there too a vesicle was found, which ultimately formed a perfect scab and adhered to the shirt. Now the sequel was this: A colored woman, living with her family some distance from the farm house where the young man was sick, washed this shirt and then her two children's clothes in the same suds; but subsequently, in putting clean clothes on them, she used for one these, for the other those that had been washed on a previous occasion. The first soon had small-pox; the second escaped at that time. Here a scab diluted with water produced small-pox, the clothes being the vehicle of contagion.

2. A gentleman having a large family of sons and daughters declared vaccination a humbug, and not one of them was vaccinated. A daughter, on her wedding tour, staid all night at a New York hotel, where a case of confluent small-pox had died, her room opening into the hall through which the corpse had been carried. In two weeks she returned, and was at a party where many young persons of each sex were assembled, when she complained of being quite sick, and her sister remarked how "feverish" her breath was. I found her next morning breaking out with small-pox; the disease was confluent and severe. But her sister and friends, with her for hours upon the night of the party, this feverish breath exhaled by her in the room, did not have the disease; every one escaped.

3. A young man having recovered from small-pox a month had his head combed by his mother, and in combing she removed a scab. Subsequently she used the comb upon her own hair, and had a severe attack of small-pox.

4. A neighboring physician, careless about washing, attended a severe case of small-pox. In feeling the patient's pulse some matter from a scab on the wrist adhered to his fingers; and having bushy whiskers which he was in the habit of rubbing, the matter lodged in them. His wife received the poison, thence took the small-pox and died.—*Am. Practitioner.*

A New Use of Alcohol.

A new use for alcohol has been discovered by a German physician of Weinheim, Dr. Schwalbe, who, if we may credit the accounts which reach us, has reported one hundred cases of various forms of tumors and glandular swellings which he has successfully treated by the subcutaneous injection of the tincture of iodine. Subsequently having injected the simple alcohol with equally favorable results, he concluded that the latter is really the effective agent. The subcutaneous injection of this fluid produces chronic inflammation of the connective tissue, by which it is caused to contract, and the pressure thus produced obliterates the lymph ducts. In some cases he has used ether in connection with alcohol in order to dissolve fats, and in this way he reports that he has cured several cases of fatty tumors. But the most important discovery of all is that alcohol thus administered prevents the extension of the cancer to neighboring tissues and lymphatic glands. By injecting the alcohol the tumor may be isolated, as it were. The contractive connective tissue then approaching the growth itself, presses upon it, stops the supply of blood, and causes it to disappear by a gradual wasting away. In connection with Dr. Hasse, Dr. Schwalbe claims that he has cured three cases of cancer of the breast in this way. We suppose that temporary cures are meant, as cancer is a disease of the blood, and is, therefore, constitutional, although locally manifested; and it is well known that the successful removal of cancer of the breast is very apt to be followed by a reappearance of the disease elsewhere.

Bee Inoculation.—A Cincinnati scientist has allowed himself to be stung once a day for three weeks by bees to ascertain the effect of the bites. He says that after about the tenth time the pain and swelling were slight, the body seeming to become inoculated with the poison.

Hot Sand Bath for the Feet.—Those who suffer with cold feet may restore the warmth to them by walking for an hour daily on the sand or earth made warm by the sun; and even a hot sand bath for the feet at home may be used as a substitute.

Insanity from Overwork.—It is asserted on medical authority that the insanity of a large proportion of the patients received into Bethlehem hospital, London, is traced directly or indirectly to overwork.

Glycerine in Medicine.

The use of glycerine for the medical compounder and practitioner are constantly being enlarged by practice and observation. In addition to its numerous and long well known uses otherwise, it has recently been found very useful as a solvent and conveyer of santonine and quinine sulphos, medicines which are often avoided when really needed on account of the repugnance which some patients feel towards tasting them. These medicines when prepared with glycerine and oil of cinnamon lose all their unpleasant taste, and will keep for an indefinite time without fermentation or other change.

Glycerine is the only known agent which will preserve vaccine lymph for any considerable time without deterioration. It has been found extremely useful in numerous skin diseases. It has been successfully employed in curing cancers—not in removing their humors from the system, but in the temporary relief of healing or driving them away when they have made their appearance upon the surface.

It has been found especially serviceable in connection with all substances used locally in diseases of the eyes, except nitrate of silver, which it decomposes.

Deafness.—In cases of deafness from deficiency, accumulation, or hardness of the cerumen glycerine is one of the best agents we possess, introduced into the canal by means of raw cotton saturated with it.

Food for Infants.—Infants raised by hand can be kept comparatively free from many of the ills to which they are prone by the substitution of from four to six drachms of glycerine, for the amount of sugar usually added to the cream, milk or water constituting their diet.

We have gathered the above facts from a paper in the Detroit *Medical Review*, by Dr. Tidd, of Middleport, Ohio. The doctor further remarks: "I confidently assert, without fear of successful contradiction, that glycerine *possesses the power of withdrawing the watery elements from any tissue to which it is continuously applied.*"

Another use for Alcohol.—In some experiments made by Dr. Horvath, a German physician, in the production of local anæsthesia, he states that if the hand be immersed for a short time in ice water, severe pain is caused, but that no such pain was produced on immersing the hand in cold alcohol, not even when the temperature of the alcohol was as low as five degrees Cent. Glycerine was found to possess a similar property. Ether caused pain, and quicksilver more acute pain still, causing the speedy withdrawal of the finger when plunged into this liquid at a temperature of three degrees. It was next ascertained that, on the finger being held for a long time in alcohol having a temperature of five degrees C., no pain was experienced, and although the finger distinctly perceived the faintest touch, sharp pricks gave no pain. This seemed to show that the application of cold alcohol has the effect of depriving the part of the special sensibility to pain, without, however, impairing the delicacy of the general tactile sensation, which, as is well known, resides in the superficial integument.

Useful Information.

The First Planing Machine.—It is an interesting question as to where the first planing machine was made; according to the London *Iron Trade Exchange* it was built in the Holland street works of John Rennie, the elder. "In March, 1814, (and we copy from an original memorandum book of the late George Rennie,) the following plan was adopted for chipping the cast iron sides of a new lathe: The sides are placed close together, with their faces upward; two planks of elm, one on each side, are bolted with their edges truly placed and upward; upon the edges of the planks run four wheels on axles, which support a track of oak. To the truck is fixed a slide rest, to which is attached a cutting tool; the truck is well loaded with weights, and pulled along the surface of the elm planks by means of a crab and chain. Thus the tool planes the iron lathe bed straight." This was, in fact, the first planing machine, crude and rude as it was, and from it Whitworth, to whom the original apparatus was shown, subsequently made a self-acting machine. We all know how important a tool it has become in the manufacture of nearly every kind of machinery.

Improving Gypsum.—It is asserted that gypsum becomes harder by placing it, after calcination, for a few minutes in a mixture of water with eight per cent. of sulphuric acid, and then calcining again. We think this quite likely to be so, as gypsum often contains quicklime, which by this treatment is also changed into a sulphate or gypsum. Alum is also known to harden plaster casts, and it is now proposed to immerse the freshly burnt gypsum in a solution of ten parts of alum and ninety parts of water, and then to calcine again. Casts made of such plaster can be polished like marble. It has surprised us that Landrin, in France, has announced as a novelty cements prepared of plaster and lime, or sulphate of lime and quicklime, (which latter changes into a carbonate.) He says that he has even used as much as seventy-five per cent. of lime; well, all our plasters are such mixtures, as pure plaster sets too quickly, so that the mixture can be smoothed better.

Utilizing Pine Leaves.

We have already, in these columns, called attention to the fact that the Austrians had discovered and were making large use of a process for utilizing the pine tree leaves or "needles." And now, according to the *Scientific American*, the industry bids fair to be put in the way of a practical trial in this country, by Mr. Charles Fulton, of New York. The coherent parts of these acicular leaves are dissolved and removed by boiling in suitable chemicals. The result is a substance resembling cotton, or perhaps more nearly wool, of a dark greenish brown color. It is prepared in four qualities, adapted for stuffing mattresses, pillows, etc., and for weaving. For the latter purpose, the fibers of the material are separated and treated in machines similar to fulling mills. Other processes follow, which result in the production of an excellent thread, which can be woven alone or mixed with wool, cotton, silk, or other fibers. Cloth of very close and fine texture is exhibited, made of the thread. It is soft and pliable, and resembles a fair quality of flannel. There is an enormous amount of raw material for this manufacture in the country, which now is of no value, and which can be obtained at simply the cost of transportation. By the process above described, it is rendered available both for textile and for paper industries, and hence may form a new and valuable supply.

Venetian Diamonds.—This is the latest imitation, and anybody who chooses can do it for himself and have a small golconda for himself, in a very short time and at a trifling cost. They are sometimes called "Parisian diamonds," from the fact of their origination in Paris. The process of preparation is described as follows: The body is of crystal (quartz) which is the hardest and best substance that could possibly be used for the purpose. Then, after the crystals are cut in proper shape, they are put into a galvanic battery, which coats them over with a liquid, that is made of diamonds which are too small to be cut and the chippings and cuttings that are taken off of diamonds during the process of shaping them. Thus all of the small particles of diamonds that have heretofore been comparatively worthless, can now, since this great discovery, be used to produce diamond liquid. The originator claims to have spent twenty-eight years in perfecting his process, which he claims to be a great discovery. What next?

Embossing Leather.—The art of embossing and ornamenting leather is not altogether a revival of the antique art as practised by the Moors, specimens of which are to be seen at this day in the Alhambra, for leather covering for furniture is found in many ancient palaces and ancestral halls of England and upon the continent. It has become a craft, though very limited in extent, developing wonderful originality and real artistic dexterity. As the Moorish designs are in a measure unfitted for modern use, modern artists are compelled to originate patterns which are consonant with the construction and style of household furniture of the present day. The recent revival of this mode of ornamentation in America is meeting with much favor, and is beginning to receive recognition as an artistic work.

Coal and Iron.—It was England's coal and iron—effectually wielded by her "Iron Duke"—which overthrew Napoleon's effort to establish the fifth great empire of the world. Had it not been for the great and superior progress which the English had at that time made in this their comparatively new and rising industry, the map of Europe would no doubt to-day have presented a very different appearance from what it does, and there would have been no Kaiser William, or any Napoleon in exile. The hammer and the forge is to-day the real ruler of the world.

Mouth glue is made by dissolving, with the aid of heat, pure glue, as parchment, glue, or gelatine, with about a quarter or one-third of its weight of coarse brown sugar, in as small a quantity of boiling water as possible. This, when perfectly liquid, should be cast into thin cakes, on a flat surface, very slightly oiled, and as it cools, cut up into pieces of a convenient size. When required for use, moisten one end. A piece kept in the desk or workbox is exceedingly convenient.

Asbestos Paper.—Asbestos pounded in a mortar till reduced to a cotton-like mass, and then freed from earthy matter in a sieve, has been put in a paper vat, and good sheets of laid paper produced in the usual way. The sheets, on being written upon, were placed in the fire, but came out uninjured, though the writing was burned out and effaced.

An Important Mechanical Hint Derived from Science.—It is said that the screw-shaped fossil from which the Archimedes limestone is named was the original of the old Athenian mechanic's idea of the screw power. So these fossils, buried four thousand feet under our prairies, tell us there is nothing new under the sun.

Beautiful semi-transparent casts of fancy articles may be taken in a compound of two parts unbaked gypsum, one part bleached beeswax, and one part paraffine. This becomes plastic at 120°, and is quite tough.

Domestic Economy.

Hints on Kitchen Economy.

Cleanliness is the most essential ingredient in the art of cooking; a dirty kitchen being a disgrace both to mistress and maid.

Be clean in your person, paying particular attention to the hands, which should always be clean.

Do not go about slipshod. Provide yourself with good, well-fitting boots. You will find them less fatiguing in a warm kitchen, than loose, untidy slippers.

Provide yourself with at least a dozen good-sized serviceable cooking-aprons, made with bibs. These will save your gowns, and keep you neat and clean. Have them made large enough around so as to nearly meet behind.

Never waste or throw away anything that can be turned to account. In warm weather, any gravies or soup that are left from the preceding day should be just boiled up, and poured into clean pans. This is particularly necessary where vegetables have been added to the preparation, as it then so soon turns sour. In cooler weather every other day will be often enough to warm up these things.

If you have a spare kitchen cupboard, keep your baked pastry in it; it preserves it crisp, and prevents it from becoming wet and heavy, which it is liable to do in the larder.

In cooking, clear as you go; that is to say, do not allow a host of basins, plates, spoons and other utensils to accumulate on the dressers and tables whilst you are engaged in preparing the dinner. By a little management and forethought, much confusion may be saved in this way. It is as easy to put a thing in its place when it is done with, as it is to keep continually moving it to find room for fresh requisites. For instance, after making a pudding, the flour-tub, pasteboard and rolling-pin should be put away, and any basins, spoons, etc., taken to the scullery, neatly packed up near the sink, to be washed when the proper time arrives. Neatness, order and method should be observed.

Never let your stock of spices, salt, seasonings, herbs, etc., dwindle down so low that, some day in the midst of preparing a large dinner, you find yourself minus a very important ingredient, thereby causing much confusion and annoyance.

If you live in the country, have your vegetables gathered from the garden at an early hour, so that there is ample time to make your search for caterpillars, etc. These disagreeable additions need never make their appearance on cauliflowers or cabbages, if the vegetable in the raw state is allowed to soak in salt and water for an hour or so. Of course, if the vegetables are not brought in till the last moment, this precaution cannot be taken.

Be very particular in cleansing all vegetables free from grit. Nothing is so unpleasant, and nothing so easily avoided, if but common care be exercised.

When you have done peeling onions, wash the knife at once, and put it away to be cleaned and do not use it for anything else until it has been cleaned. Nothing is nastier or more indicative of a slovenly and untidy cook than to use an onion knife in the preparation of any dish where the flavor of the onion is a disagreeable surprise.

After you have washed your saucepans, fish-kettles, etc., stand them before the fire for a few minutes, to get thoroughly dry inside, before putting them away. They should then be kept in a dry place, in order that they may escape the deteriorating influence of rust, and thereby be quickly destroyed. Never leave sauce-pans dirty from one day's use to be cleaned the next: it is slovenly and untidy.

Empty soups or gravies into a basin as soon as they are done; never allow them to remain all night in the stock-pot.

In copper utensils, if the tin has worn off, have it immediately replaced.

Pudding-cloths and jelly bags should have your immediate attention after being used; the former should be well washed, scalded and hung up to dry. Let them be perfectly aired before being folded up and put in the drawer, or they will have a disagreeable smell when next wanted.

Do not be afraid of hot water in washing up dishes and dirty cooking-utensils. As these are essentially greasy, luke-warm water cannot possibly have the effect of cleansing them effectually. Do not be chary also of changing and renewing the water occasionally. You will thus save yourself much time and labor in the long run.

Clean your tins with soap and whitening, rubbed on with a flannel; wipe them with a clean, dry, soft cloth, and polish with a dry leather and powdered whitening. Mind that neither the cloth nor leather is greasy.

Do not scrub the inside of your frying-pan, as, after this operation, any preparation fried is liable to catch or burn in the pan. If the pan has become black inside, rub it with a hard crust of bread, and wash in hot water, mixed with a little soda.

If you have a large dinner to prepare, much may be got ready the day before, and many dishes are a great deal better for being thus made early. To soups and gravies this remark is particularly applicable.—*Arthur's Home Magazine.*

MINING AND SCIENTIFIC PRESS.

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, W. B. EWER, GEO. H. STRONG JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week.	1 month.	3 months.	1 year.
Per line..... .25	.80	$2.00	$5.00
One-half inch.....$1.00	3.00	7.50	24.00
One inch..... 1.50	4.00	12.00	40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper nserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the PRESS promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

San Francisco:
Saturday Morning, Nov. 6, 1875

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Fryer Process; An Improved Floor Clamp; Our Home Industries, 289. A New Process for Treating Ores; Academy of Sciences; The Damage to the Mines by the Virginia Fire, 296-7. Geology of the Yellowstone; An Improved Mill Dog; Suspension of Findley's Bank, 297.

ILLUSTRATIONS.—Clark's Improved Floor Clamp, 289. Volcanic Tufas and Breccia, Yellowstone Valley; The "Boss Dog," 297.

CORRESPONDENCE.—Travels About Santa Rosa, 290.

SCIENTIFIC PROGRESS.—Geological Importance of the Colorado Explorations; Discovery of a New Metal—Gallium; The Magnetization of Gas Spectra; Steam as a Magnetizer; What is the Sun? 291.

MECHANICAL PROGRESS.—More About Compressed Steel; Wooden Rails for Heavy Traffic; The Bessemer Converting Process to be Improved; Rapidity of Steel Rail Manufacture; Ribless Boats; Reduction in the Weight of Cars; The Monster Gun Tested; Electric Light for Locomotives, 291.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 293.

MINING SUMMARY from various counties in California, Nevada and Colorado, 293-4.

GOOD HEALTH.—How Small-pox is Communicated; A New Use of Alcohol; Bee Inoculation; Hot Sand Bath for the Feet; Insanity from Overwork; Glycerine in Medicine; Another Use for Alcohol, 295.

USEFUL INFORMATION.—The First Planing Machine; Improving Gypsum; Utilizing Pine Leaves; Veneered Diamonds; Embossing Leather; Coal and Iron; Asbestos Paper; An Important Mechanical Hint Derived from Science, 295.

DOMESTIC ECONOMY.—Hints on Kitchen Economy, 295.

MISCELLANEOUS.—Oro Fino; The C. & C. Shaft—An Immense Engineering Work; Alturas Mines, 290. Amber; Phylloxera in California; The Winter Here and at the East; The Crystal Salt Works; Products from Distillation of Coal, 294. The Woodville Mine Investigation, 297-300.

More Awards for Mechanics' Fair Exhibits.

The Board of Manegers of the Mechanics' fair met on Tuesday evening and made the following awarde in addition to those already published:

P. Mezzara, for original designs in statuary, silver medal.
W. T. Garratt, California made bells, silver medal.
John Rodgers, for lubricating cream, diploma.
Henry Lake, blacking, diploma.
G. E. Hersey, sheep shearer, diploma.

A report of the late exhibition is being drawn up by Mr. J. H. Culver, the Secretary of the Board of Managers, and exhibitors are solicited to send him any information in regard to exhibits.

DEATH OF MAYOR OTIS.—James Otis, Mayor of San Francisco, died at his residence in this city Saturday morning, Oct. 30th. He had long been a prominent merchant of this city, having arrived here in 1849 with Captain Macondray, who together established the house of Macondray & Co. Mr. Otis married the daughter of his partner, who survives with six children. He was born in Boston, and was a descendant of Harrison Gray Otis, of Revolutionary memory. He was educated to the mercantile business in that city. He held several prominent positions here, having been President of the Chamber of Commerce and a member of the Board of Supervisors. He was elected two years ago Mayor of San Francisco by the Independents. His official term would have expired in about a month. He was not a candidate for re-election, but had been mentioned for the office of Governor.

A New Process for Treating Ores.

We bring to-day to the notice of the mining population of the Pacific coast another new process for treating ores, which is worthy of more than usual attention. Miners generally are skeptical on the subject of new processes, and as we have had several of late, they may turn aside from them all as unworthy of notice. The inventors, however, should have a fair hearing and trial, and if there is anything in their improvements worthy of adoption, their claims should be acknowledged by the mining community. The process to which we refer has been tested in Washington, and is now being tested in this city, with a view to its general introduction. We went one day this week to a building on Main street, near Harrison, where the ore is being worked, and propose to lay the result of our observations before the mining public.

To premise; the process has not before been publicly described, except in the reports of the patent office, and is entirely new in its character. It doesn't claim to do impossible things in the way of working the ore for nothing, or of getting out 101 per cent. of what is in it. The invention has for its object the reducing to the metallic state, the metals contained in silver, copper, lead, zinc, and mercury ore; also metals in chemical combination with non-metallic substances; and to this end it simply consists in the application of marsh-gas (CH_4) and heat, as we shall try to describe.

The reductive quality of hydrogen gas is a fact well known to chemists; but the expense attending the generating of this agent is such as to preclude its use in practical manipulations of this character. Hydro-carbon vapors have also been named as a reductive agent; but this being a generic term, no practical idea would be conveyed by its use.

The obstacles in the way of preparing and applying many of the series of hydro-carbon vapors have rendered them as reducing agents practically useless. The object of this inventor, therefore, was not only to ascertain the best possible agent for bringing the metals contained in the ore to the metallic state, but at the same time to find out which one of the series, while it should possess the above quality, should also have the advantage of economy. By many experimental efforts he has accomplished the desideratum long sought; *i. e.* that of having a reductive agent sufficient in its effects, combined with economy in its production, ease of manipulation, and one which will give an unfailing test or evidence of reduction. The agents employed are, as before stated, marsh-gas (CH_4) and heat.

It should be particularly understood that the gas is not required in a chemically pure condition, though it may be so used if economy would justify it. When this marsh-gas is made from coal it is distilled at a high temperature in order to get an excess of that gas desired. When illuminating gas already manufactured is used, it is passed through a separate retort, filled with red hot coke, in order to convert the olefiant gas into marsh-gas. This gas can also be distilled from wood or other substances.

The ore is worked as follows: A retort is arranged in the usual way, having a head which can be hermetically sealed. The retort is furnished near one end with a suitable pipe, through which the gas is admitted from the reservoir. In this instance the gas used is the ordinary illuminating gas of the city, which is passed through a separate retort, filled with red hot coke, before being turned into the ore retort. The pipe referred to is supplied with an ordinary stop cock. At the opposite end of the retort is an escape pipe, which is also provided with a stop cock and a short branch pipe, in the end of which latter a gas burner is secured. The escape pipe has its outer end bent downward into a small barrel of water. The retort is, of course, over a suitably constructed furnace. The retort is charged with ore and the head or door hermetically sealed. Gas is admitted to the retort, which will soon expel the air therefrom. A strong red heat is now applied, when the reaction at once commences. It is noticed that during the process of reduction the gases escaping from the burner will not ignite, but as the reduction nears completion the gas emits a dull bluish flame, and increases in tone until all the metals contained in the ore are reduced to a metallic state, when the flame burns brightly—that is, if the gas possesses sufficient illuminating quality—as the brilliancy of the flame must, of course, depend upon the character of the gas used.

When the reduction is completed the ore is removed from the retort, placed in a furnace and melted with suitable flux. The malleable metals will sink to the bottom and the slag rise to the top. In case the ore contains pyrites or bisulphide of iron, it is roasted in the open air before it is introduced in the retort.

In the event of the ore containing copper and silver in combination with sulphur, as usual, and it is necessary to obtain a separation of these metals after their reduction in the retort, the spongy metals are dissolved in sulphuric acid and the sulphate of silver is then separated, while in solution, from the sulphate of copper, by an addition of common salt, which will precipitate the chloride of silver and leave the copper in solution. The chloride of silver is then treated with heat and marsh-gas.

When the ore, besides copper and silver, contains gold and lead after the reduction by heat and marsh-gas, as described, the metals can be melted in solid mass, and this alloy treated with sulphuric acid, which will dissolve the silver and copper, and leave the gold and a portion of the lead in an insoluble state. The solution containing the silver and copper is then poured off, which is treated with chloride of sodium, as stated above, and the remaining gold and lead are melted with a suitable flux. In treating the chloride of silver with marsh gas, for the purpose of reducing it to a metallic state, it is not necessary to use as high a degree of heat as when treating ores. If it is desirable to have it left after treatment in a spongy state, a dull red heat is all sufficient.

This process is the invention of Mr. Demitry Mindeleff. Our attention was first called to it a few months since by an item in a Washington, D. C., paper, which stated that Mr. T. H. Alexander, a patent attorney of that city, would shortly leave for this coast with Mr. Mindeleff for the purpose of making a test of a new process for working ores. Both these gentlemen are now here. After experimenting in Washington they came to San Francisco, put up the retorts, etc., and have been making a series of tests. Messrs. J. R. Smedberg and E. M. Robinson, with Mr. C. E. Luckhardt, have been testing the process thoroughly, and when their reports are ready we will publish what is of interest to the public in regard to the technical and economic results. If this turns out *metallic* copper, for instance, in this one process, as the inventor claims, it does away with the ten or twelve different processes usually required for this purpose. The ore, as it comes from the retort, is perfectly friable and spongy, and can be pulverized by pressure between the fingers. In some of the copper ore we saw, which had been treated by the process, the copper in an apparently metallic state, in small fibres and bunches, appeared all over the surface and through the whole mass of every lump. The coal from which the gas is made is used in the form of coke for heating the retort. The amount used per pound of ore will be shown in Mr. Smedberg's report, and Mr. Luckhardt, the metallurgist, will, of course, state the economic result and the state of the metals in the ore after passing through the retort.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Monday evening last, Dr. A. B. Stout in the Chair. Dr. G. F. Becker, of the State University, and Chas. W. Banks were elected resident members. Dr. Henri Filhol, a celebrated French scientist, and member of the Scientific Academy of Paris, who was sent by the government of France to make observations on the transit of Venus, and who is visiting San Francisco, was introduced to the society by Dr. Stout. The Chairman requested the distinguished guest to favor the society with some observations. Dr. Filhol spoke the English language imperfectly and urged this as an excuse for not acceding to the invitation of the Chairman, but he was prevailed upon to address the members briefly.

W. E. Burleigh has sent to the society from the island of St. George, Alaska, one full grown male fur seal, one full grown female fur seal, one fœtus (nearly full grown) of fur seal, one sea lion, two months old; the head of a young walrus, two years old. The fur seals were carefully selected specimens. They were sent with the skull and limb bones attached. All are well preserved in salt and are suitable for stuffing, as is also the sea lion and walrus head. It is the intention of the society to have these donations from Mr. Burleigh stuffed and displayed in the Academy.

Dr. A. C. Parry, a distinguished botanist now on a visit to this coast, read a short paper on "Botany and Horticulture in California." His views were those of a sojourner among us, and expressed surprise that in this climate, where there is such a wide field for the horticulturist, that no public botanical gardens had been established. He saw in many gardens in San Francisco and Oakland more plants of foreign varieties than home production. It seemed to him that only very few of our native plants were cultivated in the garden, although elsewhere the California plants were considered beautiful and choice. Some of the most celebrated native flowers and shrubs could not be seen anywhere growing in the gardens of San Francisco or Oakland, their places being filled with certain common foreign plants. He thought this was due to a want of proper appreciation of our floral beauties and could only be remedied by the dissemination of more general botanical knowledge.

Dr. Gibbons pointed out the peculiarity of our rain storms in comparison with those of the Eastern States, and gave quite an interesting lecture on the meteorological peculiarities of this locality. He deplored the fact that so little on this subject was taught in our public schools, and thought that the children should all be instructed better in meteorology. He doubted if one in ten of the children could tell why cloude formed, or what made it rain, or why the seasons changed. Our idea is that this would apply to grown up people as well as the children, for this kind of useful knowledge is extremely scarce. At the conclusion of Dr. Gibbons' remarks the Academy adjourned.

PANAMINT shipped nearly $74,000 worth of bullion for the first half of last month.

The Damage to the Mines by the Virginia Fire.

The energetic people of Virginia are already rebuilding and repairing the damages of the late fire. The insurance adjusters who went up there have issued a memorial to the effect that in view of the present condition of the water supply, street mains and hydrants (developed by the recent fire) and of the large preponderance of inflammable material comprising the city, they deem it highly impolitic, unwise and unsafe to continue to underwrite, and thereby expose the capitals of the insurance companies to greater disaster; and they will consider it their duty to so represent to their respective companies, and advise a discontinuance of further business unless the following improvements be made:

First—The construction of water works with a twelve or eighteen inch main on C street, and six-inch connections on parallel and cross streets, with not less than four hydrants on each block.

Second—The establishment of a proper fire limit in the business portion of the city, within which no wooden structure shall be erected.

Third—The widening of the cross streets.

The Virginia papers see the propriety of all this except the fire limit part of it, to which they object, as the ruin has been so great it would be impossible to compel men to build brick or stone houses. The insurance men, however, having lost nearly two million dollars insist that prompt, radical measures are necessary to prevent a repetition of similar disasters and to induce the underwriters to insure property in Virginia.

We see by the local papers that in every direction buildings are going up, and large gangs of laborers are wheeling bricks from the ruins, cleaning and piling them for use. Toppling walls are being pulled down, lumber hauled and everything being done toward rebuilding the city. Not a moment of time is being lost. In places where the fire still smolders, and renders the bricks too hot for handling, one gang of men dashes water over them while others bear them off. Lumber is scarce, but is hourly becoming more plentiful.

In regard to the Consolidated Virginia mine the Gold Hill *News* states that the loss of the hoisting works machinery, assay office, lumber and supplies alone will not fall far short of $1,000,000. The lose of the mill amounts to $431,000, which will swell the sum total to $1,500,000. The cages were stopped in the shaft 40 feet below the surface, covered with rock and earth, and the shaft saved complete. All the books, papers, deeds and accounts of every description were saved complete, so that not even a scrap was lost. The C. & C. shaft and works were also saved by a gigantic effort. Supply of ore being entirely cut off, the remainder of the mills will of course have to shut down when their present supply of ore is exhausted. The morning after the fire Superintendent Fair had orders at the mills in the mountains for lumber to rebuild the entire works, and men are at work preparing the grounds.

The Ophir hoisting works, office and surrounding buildings, along with a large amount of wood, lumber and other supplies, were totally destroyed. The loss of the hoisting works alone will amount to not less than $250,000, while the loss of supplies for winter use will probably foot up $50,000. The works were insured for $60,000, in some of the best English companies, so that the actual loss will not fall a great deal short of $250,000. As a matter of course, when the supply of ore in the dumps end at the mills is exhausted, the mills must stop, as there is nowhere else at the present time a sufficient amount of ore being extracted to keep them running. Every effort was made to save the shaft and mine, and so far as the shaft is concerned, with almost perfect success. The safeties of the cages were sprung in the shaft at a depth of 30 feet below the surface and then covered with earth and rock, which prevented the descent of the flames and saved the mines from destruction. The larger pieces of the pumping and hoisting machinery are but little, if any, damaged, so that much of it will do to use again.

Advices dated on the 2d inst. stated that a snow storm had suspended work to a great extent, and it would not be resumed until the storm ceased. Work on Consolidated Virginia and Ophir has not been interrupted. Despite the snow and rain it will be pushed on to steady completion, if men and money can do it. The work of retimbering the burned part of the shaft has been completed, and a donkey engine has been set up, and the bailing out of water in the mine begun from the new combination shaft. The Ophir company has procured a double hoisting engine, and from the New York mine the pump and connecting rods. Machinery will be set up as soon as possible. It is the same as was destroyed in the Ophir works. The machinery in the incline hoisting works is little damaged, but the heavy foundations are totally ruined. It was expected that the railroad tunnel would be completed on the 3d inst., when the necessary mining timbers could be deposited on the ground. The storm will to some extent injure the machinery, etc Mr. Mackey says he has 10,000,000 feet of lum

ber at Huffaker's, waiting to be used in the construction of the Consolidated Virginia hoisting worke, which will be brought in as soon as the railroad tunnel is completed. When this is done some 800 men will be put at work, and the Ophir will employ perhaps 500 more. Mackey is certain that with this force the works of both companies will be finished within 30 days, and everything running as before the fire. Tools and stores to the value of $50,000 were destroyed in the Consolidated Virginia storehouse, and new ones have been ordered by telegraph from San Francisco. The smaller parts of the machinery were greatly damaged, but are being repaired by the Virginia foundries. Very little new casting will be needed, and this will come from San Francisco. The usual dividend will be declared on Consolidated Virginia for this month, over a million and a half in bullion having already been turned out from the mine, while the surplus of cash on hand is considerable. The stockholders will suffer none from the destruction of the works, either in the form of an assessment or a failure to pay dividends. Such is the statement of John Mackey. Whether Ophir will find it necessary to assess or not is uncertain, many believing that such a step will not be necessary. There is now no gas, fire, or appreciable amount of water in either Ophir, Consolidated Virginia, California, Gould & Curry, Savage, or Hale & Norcross.

The loss of the stamp mill of the California will alone amount to $80,000, there being no insurance whatever. It was only by herculean effort that the C. & C. shaft and buildings were saved. At the time of the flow of water into the Consolidated Virginia mine the lower levels of the Best & Belcher were flooded with water. The lower levels of the California mine were also flooded, so that every effort of the superintendent and the employees were exhausted in efforts to control the flood until Tuesday, when the Consolidated Virginia hoisting works and the new 60-stamp mill just about completed, were swept away by a tempest of fire. Since that time the pumps in the Gould and Curry being unable to drain the flow as fast as it came, the water rose about 200 feet in the shaft, not having reached the 1500-ft level. The Gould and Curry pumps now, however, handle all the water in the mine and that which came from the Consolidated Virginia, which latter has diminished to ten inches. The buildings of this mine came near being destroyed, but were fortunately saved. They have reason to be thankful, when all have suffered around them. During the past week the Savage has had its hands full with water, having done nothing in the mine beyond pumping and endeavoring to keep water within bounds. They kept it a few feet below the 2000-ft level, with tanks on the incline and used the pump exclusively on the 1600-ft level.

The destruction of the Ophir hoisting works has stopped work in the Mexican mine altogether, as well as in the Union Consolidated. A comparatively small amount of ore from the Consolidated Virginia is being hoisted through the Gould & Curry. The resources of the mines are immense, and there is plenty of bullion in the big bonanza to repair all losses by the recent great calamity. Merely the regular Consolidated Virginia dividend for a single month is sufficient to replace all the hoisting works destroyed.

The Utah mine has a number of men briskly employed clearing away the debris of their burnt hoisting works, and are preparing for the erection of new machinery. The contract for engines and boilers has been let and work commenced on them. The lumber for building has only been partially delivered, on account of the burning of the railroad tunnel.

Contributions of money and supplies are being sent rapidly to the sufferers by the fire. The relief committee in this city have done good work, and San Francisco cash contributions, on Tuesday night, amounted to $24,871. In addition to this, large quantities of blankets, clothing, provisions, etc., have been forwarded. Wells, Fargo & Co. have forwarded from different places $7,533 in cash; but the total value of goods received by them cannot be estimated, The committee have met with open-handedness everywhere, and from all classes, so that the suffering of the homeless people of Virginia is being rapidly relieved.

Geology of the Yellowstone.

We give on this page a sketch showing some of the geological peculiarities of the Yellowstone valley, as observed by the Government survey under Prof. Hayden. This sketch shows quite clearly the stratified character of the tufas and breccias. The entire mass is most curiously variegated in color, from an ashen-cream color to deep purple. The series of gray volcanic ashes alternates with more or less coarse strata of breccias, the fragments cemented with the tufas. This sketch shows a curious instance of a sort of unconformability, showing, probably, the periods of deposition. The underlying portion had been worn into a conical shape by the waters of the lake, prior to the deposition of the slanting mass. In the background there is a lofty range of volcanic breccia or conglomerates, rising 3,000 feet above the valley.

A School of Mines has been inaugurated in connection with the Michigan University. It has assay furnaces, forges, blast furnaces and other appliances for practical work in metallurgy.

An Improved Mill Dog.

We herewith illustrate a new style of "mill dog" which will be of interest to the lumbermen of the coast. The dogs are made by Filer, Stowell & Co., Cream City iron works, Milwaukee, Wis. The manufacturers claim superiority for the following reasons:

It will seize the log and draw it to the standard. No dogs, unless they are curved and work in opposite directions, can do this successfully on all kinds of logs, as well as cants. The double-tooth is a new invention, and is the best device ever found to supplement the teeth usually need for flat surfaces, so that round logs, of whatever shape or size, whether with thick bark, thin bark, or no bark, will be seized instantly by this and held. They are made entirely of steel, and examination will demonstrate that the manner of construction is so complete and thorough as to render them the strongest and most durable of any yet made which have any pretension to approach them in excellence. For instance: the pivots on which the teeth vibrate are solid with the bed plate and one and one-eighth inch diameter of cast steel; the tap bolt shown in cut serving only to hold them in position on the pivot.

By a new arrangement of a rachet and pawl the dogs are held in whatever position they are left in the log, and there is, therefore, no possibility of their letting go. Whenever the operator, through carelessness, or design, drops the lever, all the teeth are withdrawn and recede into the standard, so that in no case can they get their noses taken off by the saw. Mill men will appreciate the danger to men, saw and dogs which is thus avoided. The leverage, and consequently strong grip, of this dog is greater than is found in any other, so that a more secure hold is obtained by this dog, with slight exertion, than is gained in others by the utmost effort. By the application of a universal joint to connecting shaft, these dogs may be attached to head blocks, which are independent of each other, so that it makes no difference whether the standards move parallel with each other or not; the dogs will operate simultaneously on each standard from the motion of the one lever. For this feature application for a patent is pending.

The dogs as usually made may be attached to any ordinary standard. They also make a standard containing the dog which may be substituted for any other standard—including the Stearn's standard, winged or otherwise. The face of the standard being wide, and the teeth of dog coming forth from the center of it, have no tendency to spring the cant, thus obviating the necessity of wings, inasmuch as they serve the same purpose. The left hand cut represents the dog in position for holding a round log. It will be seen that it is adapted to any size, as two or more teeth are sure to enter and hold it so securely that the makers are willing to guarantee that any ordinary size up to eighteen inches may entirely be sawed up from the first dogging, without rolling the log at all. The cut on the right hand shows position of teeth when in a flat surface. Five or more teeth enter where the surface is wide, the supplementary teeth being driven in or not at the option of operator.

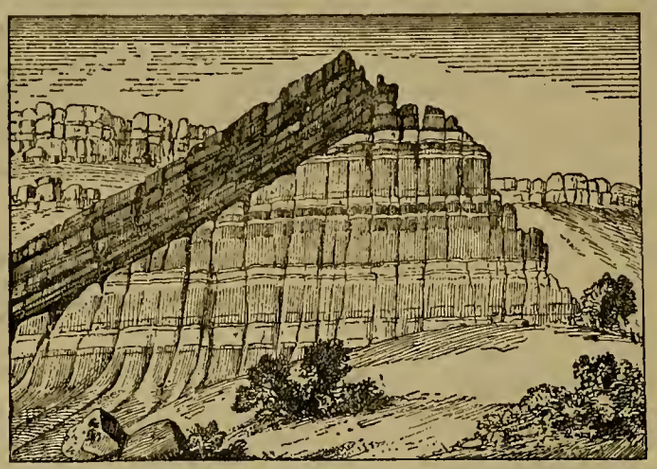
This is called the "boss dog," and it is claimed that by its use the cutting capacity of a lumber mill is greatly increased. Those desiring further information can address the manufacturers as above.

Suspension of Findley's Bank.

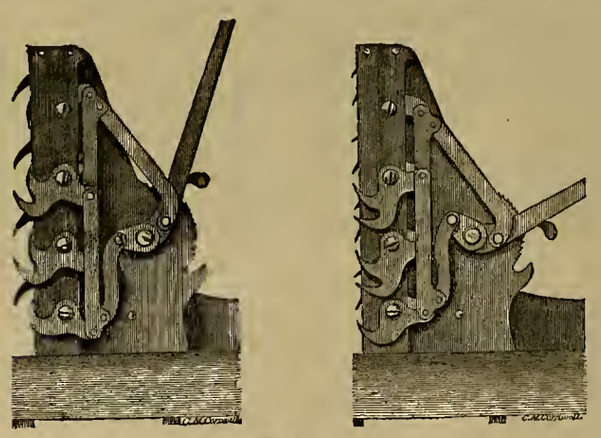
Among the financial sensations of the past week was the suspension of the bank of Thos. Findley & Co., of Grass Valley, Nevada county, which occurred on Monday, October 25th. This suspension has created much surprise in all circles, as the institution was supposed to be sound, and as Mr. Findley had earned the reputation of a careful, discreet financier, while building up his own fortune as a merchant and banker and as State Treasurer, his record while in this position being particularly meritorious. As a merchant, Mr. Findley was noted for his accommodations to "prospectors" and miners of small means, and as a banker he carried out the same rule in his connection with the later and more extensive mining operations of Nevada county. Probably he needed to learn that prudence is the better part of financial as well as of physical valor. We would suggest here that we have heard that Mr. Findley and other bankers have had cause to complain that their customers do not seem to realize that there is a call for promptness, and sometimes for accommodations even, on the part of those who come in front of the banking counter as well as for those who stand behind it.

Public opinion is apparently as yet divided as to whether this is to be a permanent failure or only a temporary suspension. We hope it will be the latter. Nevada county is steadily developing a healthy, vigorous growth. She is rich in her gold mines, and for her horticultural productions she is becoming quite noted, and many a cozy little farm is nestling in her rich canons.

It was at first reported that the interests of the Nevada County narrow gauge railroad were involved in the failure or suspension of Findley's bank, but this matter seems to be definitely cleared up, and the road is now supposed to be unaffected by the occurrence.



VOLCANIC TUFAS AND BRECCIA, YELLOWSTONE VALLEY.



THE "BOSS DOG."

Hale & Duffy and F. J. McWorthy & Co., the two companies who own the extensive sulphur deposits at Rabbit Hole, in Humboldt county, are making arrangements for refining the crude sulphur at the mines. Hale & Duffy have the material for refining works at the river, and McWorthy has just received two large retorts, each of several tons capacity, and a lot of other castings and machinery for running the work.

The Woodville Mine Investigation.

The stockholders of the Woodville Consolidated mining company have shown an energetic determination in getting at the bottom of the affairs of their company, which is highly commendable, and their example is a good one to stockholders in other companies who are dissatisfied with the way their affairs are managed—or mismanaged—by the trustees. The Committee of Eleven, appointed by the stockholders, reported at the meeting held on Wednesday evening last, and their report, which we append, speaks for itself, giving a complete history of the "inside" transactions. The history of the trouble between the officers and a portion of the stockholders is familiar to the public. The results so far show that where there is a fixed determination on the part of stockholders to investigate the management, it can be done, though as many failures have previously been made. The rottenness in this company no doubt exists in many others, and the sooner all such are cleaned out and the trustees removed the better it will be for the mining interests. Before giving the report it should be stated that in the course of this business a point of great interest, involving the right of a stockholder in an incorporated company to examine the books and affairs, has been decided.

It was the case of Wm. N. Helman, secretary of the "Woodville Consolidated silver mining company," who had been arrested on complaint of A. P. Needles, for a violation of Section No. 565 of the Penal Code, which provides that "Every officer or agent of any corporation having or keeping an office in this State, who has in his custody or control any book, paper or document of such corporation, and who refuses to give to any stockholder or member of such corporation, lawfully demanding during office hours, to inspect or take a copy of the same, or any part thereof, a reasonable opportunity to do so, is guilty of a misdemeanor."

Special counsel for the prosecution opened the case by introducing in evidence a certified copy of the articles of incorporation of the Woodville company, and proving that the defendant Helman is and has been for some time past the secretary of the company.

The complainant, Mr. A. P. Needles, who is chairman of a committee appointed by the dissatisfied stockholders to investigate the affairs of the Woodville, was sworn and said: I have been a stockholder in the company for six months. On the 13th of October had twenty-five shares of the stock transferred in my name on the books of the company. On the 26th of last October, at about 1 o'clock in the afternoon, I went to the office of the company accompanied by Michael Hayes and T. Rodgers Johnson. Know the defendant as the secretary of the company. Had been to the office before and had asked for permission to copy the minutes. On this occasion had asked for permission to copy them and was refused. I asked Mr. Helman several times, but he still refused. Thereupon I read

A Written Demand

For the books. The demand is as follows:

San Francisco, October 25th, 1875.

W. M. Helman, Secretary, Etc.—Sir: Being a stockholder in the Woodville Consolidated silver mining company, and desiring an inspection and copy of the journal of proceedings, or book of minutes of the Directors of the Woodville Consolidated silver mining company, I demand of you such inspection for the purpose aforesaid. And in order that you may not be uninformed as to your criminal liability in the premises in the event of your refusal, I would refer you to section 565 of the Penal Code of the State of California. And I desire to inform you that unless my demand is complied with I shall certainly cause you to be arrested and prosecuted. A. P. Needles.

This was read in the presence of several persons. His response was that he had been ordered by the directors not to allow the minutes to be copied. I asked him if he refused to allow me to copy the minutes. He evaded a direct answer and hesitated. Asked him again if he refused, and he said, I refuse to allow you to copy them.

Mr. Helman said he did not refuse to allow the books to be examined, but refused to have copies made from the minute book, as the trustees had ordered him not to give any one permission to do so. The counsel on both sides argued the case at some length, after which the court found the defendant guilty as charged.

John W. Pearson, the president of the company, who had been arrested on a charge similar to that of which the secretary was convicted, was called for trial. The evidence was not sufficient to warrant a conviction, and the case dismissed.

The Investigating Committee's report is as follows:

To the Stockholders of the Woodville Consolidated Silver Mining Company—Gentlemen:—As your Committee of Eleven, appointed by you to investigate the affairs of the company, we beg to submit the following:

We have had six general and many special

OF INTEREST TO
MINING COMPANIES.
A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially *machinery for mechanical ore concentration*, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

Miners and Capitalists.
Assistance is required to develop an extensive Gravel Mine on the richest lead in Sierra County—the above has been thoroughly prospected, and proved to be rich. For further particulars,
Address "B M," This Office.

THE TURBINE.

Simplest, Cheapest, and Most Durable.
The Inventor of the Dexter Windmill has made new and useful improvements in Windmills, patented March 16th, 1875, and now feels confident of having the SIMPLEST, CHEAPEST, MOST DURABLE, and
ONLY PERMANENT WINDMILL
IN THE WORLD.
SIMPLEST, because it is less complicated; CHEAPEST, because it never needs repair, standing on a firm foundation; MOST DURABLE, because it is all under cover, and has less rigging to get out of order; ONLY PERMANENT, because the only Windmill in the world that has never been injured by storms. Hundreds of people, who have thought the Dexter perfect, will be glad to observe the SUPERIORITY OF THE TURBINE over all predecessors. Although much improved, the price of mills remain the same as formerly. Persons who study their own interest will investigate the TURBINE before purchasing any other.
Territory for sale outside of California, at reasonable rates and easy terms.
Mills built to order of the best material, and at the shortest notice, by Kimball Manufacturing Company, corner Fourth and Bryant streets, San Francisco. Any orders sent to their address will receive prompt attention.

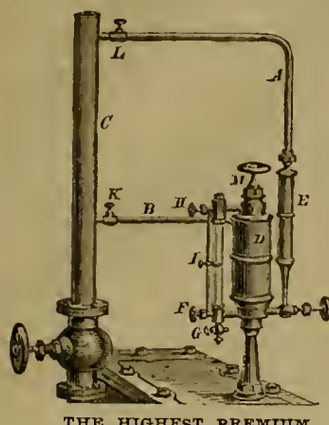
N. Seibert's Eureka Lubricators.



THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used: feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stopps; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Manufactured by California Brass Works, 126 First street, S. F. 24v23

ROOT'S "SAFETY" BOILER

MANUFACTURED BY THE

Abendroth & Root M'f'g Co.,

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]
Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

Manufacturers of
PORTABLE & STATIONARY STEAM
ENGINES,

From two to two hundred Horse Power. Send for illustrated catalogue.

WIRE ROPE

For Mining, Shipping, and General Purposes.

All kinds and sizes on hand, or made to order; guaranteed of unsurpassed quality, and manufactured of any length. FLAT ROPES, ROUND ROPES and TAPER ROPES, of IRON OR STEEL.

Patent Endless Wire Ropeway

(WIRE TRAMWAY,)
FOR THE RAPID AND ECONOMICAL TRANSPORTATION OF ORES AND OTHER MATERIAL OVER MOUNTAINOUS AND DIFFICULT ROADS.

This system has been in use for over three years, and given thorough satisfaction.

PATENT GRIP PULLEY,
for transmission of power by means of wire ropes

WIRE.

Fencing Wire and Staples.
ANNEALING WIRE,
SPRING WIRE,
GALVANIZED WIRE,
BROOM WIRE,
STEEL WIRE,
COPPER WIRE,
BRASS WIRE,

And Wire of all kinds, on hand or made to order.

SOLE AGENT FOR
Richard Johnson and Nephews' Celebrated Telegraph Wire.

Full stock on hand in bond, or duty paid.

Wire Cloth and Wire Netting.

FULL ASSORTMENT ON HAND FOR ALL PURPOSES, AND

All Kinds of Goods in the Wire Line.

Send for Circulars, Etc., to

A. S. HALLIDIE,
113 and 115 Pine Street, S. F.

LEVI STRAUSS & CO.,

Patent Riveted
Clothing,
14 & 16 Battery St.,
San Francisco.

These goods are specially adapted for the use of FARMERS, MECHANICS, MINERS, and WORKING MEN in general. They are manufactured of the Best Material, and in a Superior Manner. A trial will convince everybody of this fact.

(Continued from Page 297.)

sessions, and our labors hsvs been srdnons, disagreesble snd difficnlt, snd msde especially ao by the refusal of Mr. Pesrson to allow tbe committee free access to tbe books, papers snd voncbers, and by his refnsal to meet with us or give ns ia any way information relative to tbe working of ths mine, which was justly due na as atockholders.

Ws think, howevsr, thet the fscts snd information wa propose prssenting will be of sufficient importance to enable you to take necessaary measnrea to redress your jnat causes for grievsnce.

Ths abstrsct of msttera of record wss taken from the minnte books in ths office of the company, and wonld doubtless be mucb fuller and more complete hed the ordera given hy Pearson to allow no frntaer copies to be mads not been so faithfully carried out. We give yon, however, brief sbatracts of ths minntes of nesrly every meeting held whersin snything of importance was done from ths time of tbe incorporation of the Woodville gold snd silver mining company down to the preaent.

History of the Company.

We find that the Woodville gold snd silver mining company was incorporated May 6th, 1872, with a capital stock of $2,800,000, divided into 28,000 shsrea of a par value of $100 sach, and thst the following named gentlemen were ita trustees, viz.: J. A. Pritcherd, M. D. Townsend, W. H. Sears, W. F. Myres and Cbarlss Jonea. Batween this meeting and one held October 9th, 1874, nothing of importance transpired, but in order that we might show you the time and date thet J. W. Pearson first became connected with the mine as a truatee, we were obliged to trace the miantes through, which brings us to the meeting of October 9th, 1874, when the cepital atock of the company was increasad from the sum of $2,800,000 to $6,000,-000. At the time of this increase or watering, the trusteea were John W. Pearson, G. D. Roberts, and Wm. Sherman, witb two others, whose namea we did not get. John W. Pearson was president, end Wm. Helman, secretary.

On the 14th of January, 1875, tbe Woodville Consolidated silver mining company, and known to some as "Paarson'a Bonanza," was incorporated, with a capital stock of $12,000,000 divided into 120,000 shares, with Wm. Sherman, Robert Sberwood, J. R. Lee, J. S. Wall, and H. G. Maynard es trustees. We beg of tbese of yon who mias tbe name of Pearson from tbe directory, not to think for a moment that he is not tbere, for from the evidence which ia continnally fonnd, he seems to be head and foremost in every important measure connected with tbe mine.

Jannary 20, 1875, another meeting was held, the minutea of wbich show the following disposition of a portion of the 120,000 shares of the Woodville Consolideted. At tais meeting it was voted to issue to the following nemed companies 47,500 shares, on their execnting to this company a good and anfficient deed, said shares to be isaned as follows:

Blue Ledge Company	6,000 shares.
Rogers Company	6,000 shares.
Perieman Company	8,000 shares.
Coso or Surplus Company	8,000 shares.
North Woodville Company	6,000 shares.
Sonth Woodville Company	7,500 shares.
Ramsdell Company	6,000 shares.

In addition to thia, it was voted to issne 60,-000 ahares, or one-half the capital stock of this company, to the Woodville Silver Mining Co., (Jobu W. Paaraon, preaident,) on their deeding to this company tbeir aole and entire property. The balance of the 120 sharea is unaccounted. Pinned to the minntes we fonnd a memorandum made in pencil, as follows: "Hyde, Barrett, Ramsdell and Ambross got 6,600 shares, instead of Ramsdell 6,000, as per book, and signed 'Pearson.'" It appears that while tbe meeting disposed of their vote of bnt 47,500 sberea to tbese outside companies, that one compsny whoae portion was bnt 6,000 shares got, as Mr. Pearson's memoranda reads, 600 sharea more than belonged to them.

How the Shares Went.

It will perhaps be remembered by many, if not ell of yon who were present at the meeting held in tbe police coart rooms, Oct. 9th, tbat Mr. Pearson stated that the Woodville Conaoli dated had purchased but one outside claim end that was purchesed on the advice of the attorneya of the company; and yet yon will notice by tbe records that instead of but one claim being purchased, our stock was issued to seven different compenies for and in consideration of their executing to this compauy good and sufficient deeds, etc. There seems to be a question of veracity between Pearson and the records, with every evidence of the records being ahead; hnt worse thnn this is the faot tbet these purchases are entirely valueless, and evidence can be produced to prove this and will be submitted whenever you see fit to take this matter into tbe oourts.

Tbese pnrchasea ehow the disposition of the Woodville Consolidated atock aa follows:

Forty-eight thousand one bnndred sha es for worthless property nnd 60,000 sharea for Woodville G. & S. M. Co., the stock of which was issued to John W. Pearson, leaving still unaccounted for 11,900 shares.

Fully appreciating the anxiety you might feel to know who the Messrs. Hyde, Barrett, Ramsdell & Ambross were, to whom 6,600 abares were issued, instead of tbe 6,000 sbares aseigned to Ramsdell, as per tbe minntes of the meeting, we tried to ascertain, but are sorry to report not even progress, and can only refer you to Mr. Pearson, who must know them, elae he wouldn't have been so liberal witb the atock as to have given them 600 shares more than ths meeting voted to issue to tbem.

Jsnusry 27, 1875, J. S. Wall resigned as trnstee, and John W. Pearaon waa elected in hia stead.

At thia meeting the president and secretary were instructed to issne 60,000 shsrea of its cspital stock to ths stockholders of ths Woodville gold and silver mining compsny, *pro rata*, and the secrstary was instrncted to deliver ssid stock so issusd *pro rata* to the stockholdera of said Woodville gold and silvsr mining company, in exchange for the sbarea held by thsm, and to cancel asid stock as soon as received.

March 25, 1875, ws find record of sn amendment to the meeting of January 27th, sa follows: The president snd secretsry of the Woodville Consolidated silver mining compsny shall st once isane to the president snd secrstery of the Woodville gold and silver mining company 60,000 shares of its cspital stock, to be by them distributed to the atockholders of said Woodville gold and silver mining compsny.

The original motion, Janoery 27th, was that the president and secretary of the Woodville Conaolidated wers instructed to isaue the 60,-000 sharsa to ths atockholdera of the Woodville gold and silver mining company, and ths smendment provides thet tbey shall issue it to tbe president (John W. Pesrson) and secretery, to be distribnted by them to those stockholdera.

There may be no particular difference; but if not why was anch an amendmsnt offered nearly sixty daya afterwards? At thia aame meeting Mr. Pearson made a motion, which waa aeconded by Williem Sherman, that the president and secretary were anthorized to issne the company's promissory note for belance dne on note dua the Woodville gold and silver mining company, which was held by the National Gold bank and trust company, amonnting to $30,-000 and interest. How tbis company became interested in this note, or why such promissory note was issued by this compeny, is a matter which, together with many others connected with the manegement of this company, we trust yon will aee fit to take into the conrt.

On motion of Mr. Lee, seconded by Mr. Pearson, assesement No. 1, of $1 per ahare, was levied npon the capital atook of the company, amounting to $120,000.

How Pearson Worked the Mine.

April 12, 1875, on motion of Mr. Lee, seoonded by Mr. Maynard, it waa resolved that the president and secretary be anthorized to issue the company's aixty-day note in favor of John W. Pearson, in settlement of balance dne him at this dete aa treasurer, amounting to $93,-425.11. Tbis is another matter, and of no small importance to yon, that should be ventileted in the courts.

With the shaft down less tban 600 feet, the last 100 feet of which was let by Mr. Crossman, the superintendent, for $30 per foot, it is not quite easy from the data wa have to aacertain how tbe company became indebted to tbe treasnrer, Mr. Pearson, in the snm of over $90,000. And yet it don't end here; for May 13tb, 1875, jnst thirty deys after, we find the president and secretary are suthorized, on motion of this same Mr. Lee, to issue the company's ninety-day note in favor of John W. Pearson for $51,958.56, tbe amount due him as traasnrer at this date, at a rate of interest not to exceed one and one-half per cent. per montb.

Within thirty days the company's notes were issued to John W. Pearaon for tbe snm of over $140,000.

The only record of any expenditnres being made during this time of more than ordinary was this, wbich was found spread npon the minutes of the same meeting, *i. e.*: *Resolved*, that the contract entered into on behalf of the company by Superintendent Crossman, for sinking 100 feet of shaft at $30 per foot (contractors to pay the company's chief engineer), be and the seme is ratified, and tbat the bookkeeper at the mine be inatrncted to obtain a copy of the contract end forward to this office forthwith.

The contract for $30 per foot, owing to the independent action of Superintendent Crossmen, saved you $60 per foot, or $6,000, as J. H. Pearson stated to Mr. Crossman tbat he hed made arrangementa with his brother, John W. Pearson, to take the shaft at $90 per foot. This action on tbe pert of Mr. Crosaman accounts for the motion made at a later meeting that tbe superintendent be probibited from making contracts in bebelf of the company without the consent and approval of the Boerd of Trnstees, and, still furtber or later, the motion by Mr. Pearson tbet Superintendent Crossman'a salary be discontinned from July 1st, etc.

Mr. Sberman moved that the foreman be discharged, and that the book-keeper, Mr. J. H. Pearson, be instructed to act as foreman in the absence of the superintendent.

Motion of Sherman aod seconded by Mr. Pearaon, it was resolved that the superintendent is hereby anthorized to make all necessary porohesea of material for the sinking of 100 feet of shaft, and send bille for ssme, npproved by himself, to the book-keeper, J. H. Pearson, for payment, who alone is autborized to receive all moneys and make all disbnrsements.

Mr. John W. Pearson, as treasurer, located in San Francisco, and bis brother, J. H. Pearson, as financial agent, at Gold Hill, ought to have given the Pearson family very nearly supreme control of the financea, and there can be bnt little doubt, from appsarsncea, that it did.

Tracing the Records.

Upon motion of Mr. Sberman it waa reaolved that the anperintendent be prohibited from making contrscts in behslf of ths compeny witbout the consent and approvsl of the Bosrd of Directors. June 25th, 1875, on motion of Mr. Pearson, it wsa resolved tbat while the compauy is only sinking its shafts, the wbole concern shall be run and msnsged by tbis Bosrd, and ths company'aforemsn, J. H. Pearson, and tbat Snperintendent Crossman's salsry be discontinued from July 1st next, until such time as this Bosrd shall order him snd hs doss take possession of the compsny's mine snd mills. This movs on ths part of Mr. Pearson is the only ons connected with his managemsnt tbet ws can find that savors in the least of a disposition to do hia duty by the stockholders, and is moat likely accounted for by the fact that it wsa a promotion for his brother, J. H. Peareon. On motion of J. W. Psarson, it waa resolved thet assessment No. 2, of 60 cents per ahsrs, be levied upon the capital stock, amonnting to $72,000.

July 9th, 1875, on motion of Mr. Pearson, H. G. Maynsrd's seat as trustee was declsrsd vacsnt, by rsason of his fsilnre to place atock in his nams on ths booka of the company, and E. M. Seaton was elected in his stead.

On motion of Mr. Seston it was resolved thet the company purchsse of J. B. Hsggin as per his commnnication to thia Board of the 8th instent—on fils—certsin 53,235½ sharea of the capital stock of ths South Woodville mining company for $75,000 cash, provided that said J. B. Heggin furnishea the balance entire of tbe capital stock of the said South Woodville to this company, together with said South Woodville mining company's deeds, tranaferred to this company for the South Woodville mining company's one-third interest in the new shaft and machinery of the Woodville Consolidated silver mining company, and for that certain mine owned by said Soutb Woodville mining company, known as the Periman mine, and all property, interest and claima of seid South Woodville mining company in the State of Nevada, and that this company psy said $75,000 for aaid ahaft and machinery, mines and claims, and not for aaid stock, which atook thia company will only accept to protect it in the purchase of aaid mines and other property, togetber with good and sufficient deeds from Rogers, Hyde and Barrett for all their intersat not conaolidated. Yonr attention is called to that portion of this proposition made by Mr. Seaton so aoon after hia election aa trustee, which relates to one-third interest which the Sonth Woodville has in the new shaft and maohinery of the Woodville Consolidated, and we heg to suggest that in tbis transaction alone can be fonnd "food for tboughtful people," to aay the leest.

On motion of Mr. Pearaon, John Rowe, D. M. Seaton and Preaident Lee were appointed a oommittee to borrow, for the use of the company, to pay for tbe purchase of the Sonth Woodville company's property, $75,000, interest not to exceed two per cent. per month; and the president and secretary were autborized to issue the compeny's promissory note therefor; and that tbe said committee ahall receive and deliver to this compauy good and sufficient deeds for the claims purchased, and pay aaid money therefor.

August 21at, on motion of Mr. Pearson, it was resolved, tbat assessment No. 3 of $1 per share be levied npon each and every share of the capital stock, amonnting to $120,000; which amount, as fonnd by the booka wben examined, together with the amounts of the two previous assessments, in all $312,000, has been paid into the hands of Mr. Pearson, as treasurer.

Up to Date.

Up to this time, August 21st, 1875, and since March 25th, or within six months, you, as stockholders, have been called upon and have paid into the hands of John W. Pearson the sum of $312,000, and within the same time given the notes of your company to him for over $140,000, for balances due him as Treasurer.

In addition to this, from information which we think can be reduced to legal evidence, there hea been shipped to this city from the Woodville Consolidated mine over $130,000 in bullion. Per contra, can any one tell us tonight wbere we, as stockholders, have received a considsration for our money? What developments or improvements have been made that warrant any such expenditures? Is there any reason why you should longer submit to what appears to be extortion in the fullest senee of the word? And yet this system of mauagement does not end here, for on September 17th, 1875, a contract was entered into between Risdon, Rogers & Co. and the Woodville Consolidated mining company to furniah pumping machinery, engines and boilers on the gronnds of the company at Gold Hill, Nevada. Tbe oontract covenants, agrees and binds itself and futnre management to pay Risdon, Rogers & Co. $65,000, gold coin, 90 per cent. to be paid at the end of each month for labor and materiel as furnished; and as security, said company covenants and agrees that said Risdon, Rogers & Co. may enforce the same by law or by serving a written notice on said mining company'a superintendent or president; tbat if said payments in arrears are not made good within five days of said notice, tbat said shafts, grounds, machinery and sufficient gronnde aronnd the shaft to complete and operate the same to suit the purposes of the purchaser to operate said mine and other uses, shall be sold.

Ssid ssle to bs made, by posting notice on said shsft snd mining material five dsys, to ths higbest bidder for cash, snd said asle shall be final and have no right to redeem; and it is bereby agreed tbat Risdon, Rogers & Co. mey sell out their interest one to another, and that no member of the preaent or fnture managsment shall be held personally responsible. All extra materisl furnished or labor performed shall be psid by said company.

Ws submit this contract ss a model one of its kind, snd point out to you one of its beanties. It provides that Mr. Risdon may sell his intereat to Mr. Rogers, who then hsa control of tbe contract, and which, according to its rssding, might at any time place the whole property in ths hands of Mr. Rogers; and when we tell you that Mr. Rogers is the father-in-law of Mr. Pearson it will not be difficult for yon to draw conclusiona, which ought to satisfy yon es to whether or not it is for your interest to allow the present msnegement to continue.

October 29th tbe secratary was instructed to pay Perlman $1 25 per share for all Sonth Woodville mining stock hs may present.

In ths absence of any further information rsgerding this movs, the srrsngsmsnt appeara to be another "job." Whether it is or not is a subject for future oonsidaration. At the same mesting Messrs. Cnrtis and Mather, who wers selected by yon to act with us sa an investigeting committes, were elected as trustees of ths company by Mr. Pearaon. Mr. Pearaon made tha following propoaition by letter:

Gentlemen:—I propose to cell a meeting of the directors of the company to-morrow, at 11 o'clock A. M., at which two of our trnatees will resign, and we will elect two of your commitee in their atead as trusteea, who can and shall have full acceas to the company'a affaira; and when your committee'a trustees have reported on the company'a affaira, if they discover dishoneet management on the part of the trusteea I will join in calling a stockholder'a meating or a new election. This action on my part to atay all actions and proceedings of committee till yonr trustees and committee report. Signed,

JOHN W. PEARSON.

The Difficulties of the Investigation.

This proposition waa accepted by the committee, except the final clause, agreeing to snspend legal proceedings, under the impression at the time that it would aid us in getting at what we were appointed to ascertain, and when we tell you that up to tbia time (fonrteen days since their appointment) these two trustees have furnished us with no information or done anything that haa in tbe least furthered our efforts, you will understend something of the neture of the arrangement we were foolish enough to make by accepting Mr. Pearson's proposition.

We had hoped and expected to have been able to preaent you with such abstracts of the accounts as wonld ahow disbursemente, eto., from wbich could be deduced tbe finanoial condition of the company; but aince we cannot work up the booka, we cannot give yon these facts. We know this, however, that since thia investigation begen, counsel to fight your interest has been engaged, as followa: Two firms are paid $7,500 per year, a retainer of $250, and another of $1,000, with a further provision of $1,500; and all of these yon are paying for.

From the very best anthority we are informed tbat the mine ia worth $25 per share in thia market, and would, if managed honeatly, and by men in whom the public hed confidence, be selling for tbat to-dny.

When the inveatigation began, the stock was wortb 87½ cents per share, and is aelling to-day for — per share. This increase in price is not owing to any increased value of the mine, but is attributable wholly to the fact tbat people who know anytbing of the mine are taking the aherea largely, with the hope and expectation that the results of our investigation will be tbe means of giving the company another board of trnstees, in whom they might have confidence, wheu the stock would take its proper place npon the market and sell for nearer its troe valuation. Tbere ia uot snother stock npon the market to-day tbat ia so generally held by laboring people and in small lots as this is, and with this fact so well known by Mr. Pearaon aud his managers, it has been easier to bleed the stockholders in the way of assessments than it migbt have been otherwise. With the facts and figures we bave beén able to present you, we are satisfied that the management is fraudnlent; but we do not wish you to understand tbat we reach tbis conclusion wholly from the facta we bave presented to you to-night. We are in possesaion of such information as can only be divulged in the eoorts, and which we believe to be of sufficient importance to forever damn the present management of the Woodville Consolidated silver mining company. The air is filled with rnmors tbat another asaossment is to be levied, and that Pearson proposes aelling you out to the Justice people, etc.

The Consolations of the Action Taken.

With your co-operation we can soon pnt Mr. Pearson ont of tbe channel of levying assessments or selling to Justice the stock or property of the Woodville mine; and our labors are not to end here, aa the stand we have taken and the fight we have made have been the means of awakeniog the people to a sense of their weakness in longer anbmitting to systematic swindle by snch men as this Mr. Pearson, and in tbe many letters received by ua from nearly every town of importance in this State, as well as Nevada, we were thenked for the course we had taken, and begged to go on and carry the matter to an isane, which could not be other

than successful. Our treasnrer, Mr. Johnson, has prepared and had printed a circular letter, which explains what is necessary in order to ascertain the strength of the stockholders, and has also had printed a blank proxy, and these have been distributed throughout the State where stock is known to be held. This method seemed the best one of getting at the stockholders ont of the city, and we have good reason to believe will accomplish all that we can expect or hopo for There havo been expenses attending this investigation which to the present (if wo may except a few dollars raised at the stockholders' meeting) has been met hy the members of this committee; and in order that we may push the matter to a successful issue, and get our rights as stockholders, money must be raised to meet the expense. Various ways have been auggosted to raise the funds necessary, and the snbject is one to which your attention and consideration is called with the hope that it may be discnssod and finally arranged at this meeting.

From all our findings we are enabled to tell you that the condition of the property you are interested in (ontside the managoment) is eminently satisfactory, and assnre you that all that is necessary to place it among the first of its class is to oust the Pearson dynasty, and elect instead an honest Board of Trustees. Will you stand hy us and give us yonr aid, to the end that the property you have invested yonr money in, and which, owing to Pearson's manipulation, is next to worthless, may be wrosted from his management and placed where it belongs, and that he be compelled to disgorge all properties of the company that he has nnlawfully appropriated back into the hands of the company, thereby giving yon a chance to get a consideration for yonr money. We close this report by thanking you for your kind attention to its reading, and trusting onr efforts in yonr behalf may be correctly appreciated, and our failures kindly criticized, and sign ourselves. Respectfnlly, yours,

Michael Hayes, E. T. Kennedy, John W. McCormick, L. Summerfield, J. A. Crossman, T. Rodgers Johnson, A. P. Needles, N. P. Brook and E. A. Grow.

We concur with some of the above conclusions in the above report, but not all.—Edward Curtis, F. G. Mather.

Curtis and Mather are the two trustees selected by Pearson from the investigating committee.

The report was received with applause and adopted by a nnanimons vote. Mr. Curtis of the Committee resigned and Mr. Mather was requested hy a vote to do the same. In their stead Thomas V. O'Brien and Dr. D. S. Hutchinson were appointed and the committee continned. An assessment of ten cents per share was levied to carry the case into court, if necessary, and the meeting then adjourned to meet next Wednesday evening.

SALIVATED.—During the Virginia fire many persons who happened to be in that part of the city lying to the eastward of the Consolidated mill, at the time it was burning, were salivated by the fumes of mercury wafted through the air. Several tons of quicksilver were wafted away on the air while the mill was hnrning.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington D. C., Nov. 2, 1875.

FOR WEEK ENDING OCTOBER 19TH, 1875.*

TRACTION WHEEL.—William O. M. Berry, S. F., Cal.

CARBURETER.—Louis Marks, S. F., Cal.

STEAM BOILER INDICATOR.—Andrew Moon, S. F., Cal.

VERMIN EXTERMINATOR.—Valentine Schmidt, S. F., Cal.

PROCESS OF MAKING POISONOUS COMPOUNDS FOR DESTROYING GOPHERS, SQUIRRELS, ETC.—Jas. G. Steele, S. F., Cal.

GUARD STRAP FOR SHAFTS AND STRAP COUPLINGS.—Jas. Weatherhead, San Jose, Cal.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issne.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent bnainess for Pacific coast inventors transacted with perfect security and in the shortest possible time.

PACIFIC RURAL PRESS,

A first-class 16-page Agricultural Home Journal, filled with fresh, valnable and interesting reading. Every farmer and ruralist should take it. It is immensely popular. Subscription, $4 a year.

DEWEY & CO., Publishers,

Np. 224 Sansome street, SAN FRANCISCO.

Mothers, save the lives of your daughters when affected with consumptive coughs or violent colds, by administering to them without delay, the standard specific, HALE'S HONEY OF HOREHOUND AND TAR.

Pike's Toothache Drops cure in one minute.

DEWEY & CO.

American & Foreign Patent Agents.

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditionsly; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Bnsiness promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent bnsiness, enable us to abundantly satisfy our patrons; and our success and bnsiness are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the colnmns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Anstria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cnba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chili, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, bnt tho drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently estahlished.

Our schednle prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country sooner than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of goverment, delays are even more dangerons to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in trans mitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advise of importance to them from a short call at our office.

Remittances of money, made by individnal inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money bnt their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to onr agency

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.,

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 224 Sansome St., S. F

Mining and Scientific Press.

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi.

As a PRACTICAL MINING JOURNAL it has no rival on this Cantinent.

It is the only MECHANICAL, and the only SCIENTIFIC Journal of the Pacific States.

Miners, Assayers, Millman, and Metallurgist in the United States should take it.

Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Stndents should patronize its columns of fresh and valuable information.

Mining Engineers, Snperintendents, Metallurgists, Mine Owners and Mine Workers throughout the world should profit by its illnstrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughout the land, in high or humble sitnation, who wonld avoid literary trash for genuine information. should SUBSCRIBE AT ONCE.

DEWEY & CO.,

No. 224 Sansome street, S. F

Designing and Engraving at This Office.

We are prepared to do fine Wood Engraving for illustrating Landscape Scenery, Buildings, Machnery, Works of Art, Manufactured Articles, Trade Marks, Seals, Etc. We have a first-class

Machine for Engraving

A portion of the work, which can be finished thereby more perfectly than by the eye and hand alone. Our patrons can depend upon first-class work always, and at reasonable prices. Samples can be seen at our office.

DEWEY & CO.

UNITED STATES

Mineral Land Laws, Revised Statutes,

And Instructions and Forms Under the Same.

We have just issued a pamphlet containing the general mineral land laws of the United States, with instructions of the Commissioner of the Land Office The contents of this pamphlet comprise all of the Government laws with rolation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870 Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of $500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold. post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO.,

Publishers of MINING AND SCIENTIFIC PRESS, S. F.

"The Public Lands of California."

The demand for this new work is steadily increasing, and the more widely that its merits are becoming known, its usefulness to everyone is becoming more fully demonstrated. The map of California and Nevada alone is worth more than fifty cents, the price asked for the work, and the fact that a glance at its pages shows the products, population, etc., of each county in the State, besides the surveys of United States Land, subject to the homestead and pre-emption laws of Congress, the laws of Congress in regard to locating and holding this land, etc., renders it of inestimable value. Orders sent to Dewey & Co., enclosing fifty cents, will meet with prompt attention, as it will be forwarded immediately, post paid.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

SUTTER CREEK, February 26th, 1875.

MESSRS. DEWEY & CO.—I have received my Letters Patent through your Aagency. nd, for your prompt nsss, accept my thanks. Yours, S. N. KNIGHT.

At a Stated Term of the Circuit Court

of tha United States of America of the Ninth Jndicial Circuit in and for the District of California, held at the court room in the city and county of San Francisco, on Thursday, tha 30th day of September, in the year of our Lord one thousand eight hundred and seventy-five. Present—The Honorable Lorenzo Sawyer, Jndge.

Nicholas Seiberi, complainant, vs. Wm. T. Garratt, defendant—In equity.

DECREE.

This cause cama in to be heard at tha February Term, A. D. 1875, of this Conrt and was argued by counsel and thereupon npon consideration thereof, it was ordered, adjudged and decreed, as follows, viz: That defendant, William T. Oarratt, was not the first or original inventor, or discoverer of the improvement or discovery olaimad by him, in and by thosa certain raissned letters patent of tha United States, number five thousand three hundred and twenty-sight (No. 5328), for an alleged new and useful improvement in lubricators, issued to said defendant, William T. Oarratt, on the 18th day of March, A. D. 1873, and is not antitled to a patent therefor, and that said reissned letters patent, number five thousand three hundred and twenty-eight (No. 5328) are declared void and the same are hereby vacated and set aside by reason of their interference with those certain letters patent of the United States, number one hnndred and eleven thousand eight hnndred and eighty-one (No. 111,881) for a new and useful improvement in lubricators, issued to complainant, Nicholas Seiberi, on the fourteenth (14th) day of February, A. D. 1871.

It was also furiher ordered, adjndged and decreed that complainant do have and recover of and from defendant his costs and expenses to be taxed herein.

(Signed) LORENZO SAWYER,
Circuit Judge,

The shove decree has reference to "Seibert's Eureka Lubricator" for oiling the valves and cylinders of steam engines.

It has a glass gange and condensing pipe, or reservoir, with a regulating feed valve, and works as follows: As the water of condensation is admitted, under the oil, just so fast the oil passes out at the top through a pipe into the steam pips to oil the valves and cylinder.

Parties who infringe or purchase the infringed lubricators, will be held strictly responsible.

N. SEIBERT, Patentee,
125 First Street, S. F.

Mining and Other Companies.

Cloverdale Mining Company — Location

of principal place of business, San Francisco, California. Location of works, Cinnabar District, Sonama County, California.

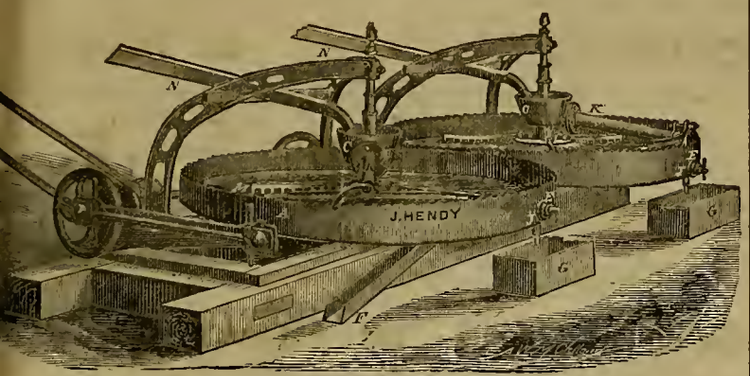
BY THE USE OF

Hendy's Improved Amalgamator and Concentrator



Can be seen at the Manufactory, No. 32 Fremont Street, San Francisco.

SAN FRANCISCO, April 27, 1872.

JOSHUA HENDY, Esq.—*Dear Sir:*—As a practical miner and millman, I take pleasure in recommending the use of your Concentrators in all mills where gold or silver ores are reduced. No mills should be without them, for the following reasons:

1st. They are good sizers (no perfect concentration in pulverized ores can be effected without first sizing).
2d. The best Concentrator I have ever known—(the concentrated stuff only containing 5 per cent. of sand).
3d. They are good amalgamators, light (feathery) particles of amalgam and particles of coated gold by attrition are brightened, and from their specific gravity and the action of the pan, fall to the bottom and adhere.
4th. They require but little power and attention to run them, and with ordinary care will last for years.

I have been familiar with the workings of your Concentrators for four years past; have run them myself in the North Star Mine, Grass Valley; am familiar with their practical workings on the Empire Mine, Grass Valley, St. Patrick, Placer Co., St. Lawrence, El Dorado Co., Oaks and Reese, Mariposa Co., and most cheerfully give you this testimonial. For further information you are at liberty to refer to,

Yours respectfully, JAS. H. CROSSMAN, M. E.

409 California street, or Cosmopolitan Hotel.

SAN FRANCISCO, February 10, 1874.

OFFICE SUPERINTENDENT OF KEYSTONE CON. M. CO., AMADOR, AMADOR COUNTY.

MR. J. HENDY—*Dear Sir:*—In answer to your inquiries as to your Concentrators furnished our company last July, I would say that I am more than pleased with them; and the saving to the company has been over $3,500 per month more than with the blankets and huddles formerly in use. O. C. HEWITT, Supt.

OFFICE SUMNER MINE, KERNVILLE, April 27, 1874.

J. HENDY, Esq.—*Dear Sir:* Having four of your Concentrators in use at our Mills for four or five months, which for saving Amalgam and for concentrating Sulphurets, are a success, beyond a doubt, I feel it a duty I owe you and those interested in Quartz Mills, to recommend them.

As further evidence of their worth, I now order TWELVE more of your Machines for our new Mill, now in course of erection. E. R. BURKE, Superintendent.

For description send for Circular.

HARRISON'S

LIGHT VERTICAL BURR MILLS

BARBER & BACON, MILLERS AND LUMBER DEALERS, SOUTH VERNON, VT., write July 15th:

"We have been running two of your LIGHT VERTICAL CORN MILLS for the past 6 months with remarkable results, and have ground over 80,000 bushels of corn into No. 1 meal in that time, running the grist-mill nights only, as we run our saw-mill in the day time. We have often ground in the 20-inch Mill (which weighs about 500 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 24,300 lbs., or 432 bushels. To do this we have to run at a speed of 1,300 turns per minute, and use about a 20-horse power. You may refer parties to us for further information, and when we have tested your HEAVY VERTICAL MILL, we shall take great pleasure in giving the results."

Works, King street, bet. Second and Third. fe15-eow

F. MANSELL & CO.,

SIGN PAINTERS,

423 PINE STREET,

(Between Montgomery and Kearny.)

Persons engaged in the following business can have their Signs Painted at contract prices, for goods or articles in which they trade, viz:

Merchant Tailors,	Gents' Furnish'g G'ds,
Bootmakers,	Furniture Dealers,
Hatters,	Jewelers,
Hotels,	Piano Fortes,
Wine Merchants, Etc., Etc.	

De Crano Metallurgical Works and Assay Office,

412 Commercial Street, S. F.,

Assaying in all its branches, ores analyzed, ores worked by mill process or otherwise. All assays guaranteed to correspond with U. S. mint assays. Silver and gold assay, $2.00; lead assay, $3.00; copper assay, $4.00.

J. S. CURTIS, Metallurgist.

SAN FRANCISCO

Pioneer Screen Works,

Removed to 32 Fremont Street, near Market.

SCREENS

J. W. QUICK,

Manufacturer of perforated sheet metals of every description, at reduced rates. Mill owners using Battery Screens extensively, can contract for large supplies at favorable rates. This is the only establishment on the Coast devoted exclusively to the manufacture of Screens

PURCHASERS please say advertised in Scientific Press.

Thursday Noon our last forms go to press. Communications should be received a week in advance and advertisements as early in the week as possible.

A COMPLIMENT.—It is proper to say that the MINING AND SCIENTIFIC PRESS is the best publication of its class on the Continent, and we are glad to know that it is appreciated and liberally patronized by those in whose interests it is published.—*Placer Argus.*

MINING AND MILL MACHINERY.

HOISTING AND MINING ENGINES.

We have all sizes of COOK, RYMES & CO.'s Celebrated Hoisting Engines. These Engines are well known from Alaska to Mexico, and need no recommendation from us. They are made of the best material, and have been lately greatly improved with large drums and link motions.

—OUR—

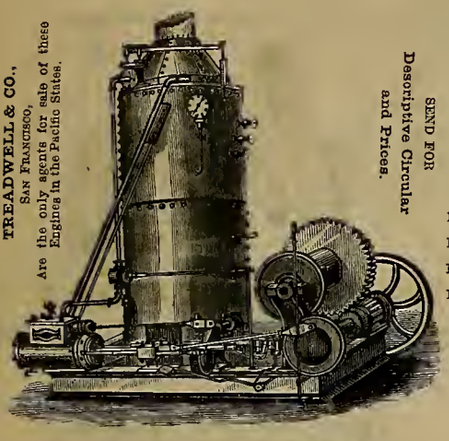
DOUBLE-DRUM MINING ENGINE,

MADE BY SAME PARTIES, IS THE MOST COMPLETE HOISTING RIG EVER INTRODUCED TO THE MINES OF PACIFIC COAST. THE PLANS AND SPECIFICATIONS WERE MADE BY ONE OF THE FIRST MINING ENGINEERS AT VIRGINIA, NEVADA. THESE ENGINES MAY BE SEEN IN SUCCESSFUL OPERATION AT THE FOLLOWING MINES, IN VIRGINIA OR GOLD HILL:

Ophir, Belcher,
Chollar, Con. Virginia,
Europa, Niagara, Leviathan,
Phil. Sheridan, No. Con Virginia.

☞ We have three sizes of these Mining Engines, and are prepared to fill orders at short notice. Prices and full information sent on application to

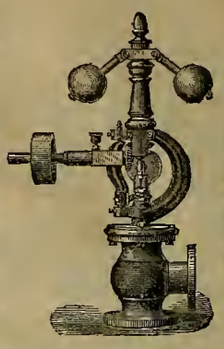
TREADWELL & CO.'s Are the only agents for sale of these Engines in the Pacific States.



SEND FOR Descriptive Circular and Prices.

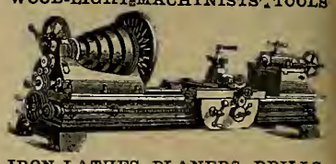
COOK-RYMES HOISTING ENGINES,
5½x12—6x12—7x12—8x12—9x14,
Always on hand, with or without reverse motion, either horizontal or upright cylinders, and with or without trucks.

Gardner Automatic Safety-Stop Governor



Send for Circular and Price List of this Celebrated Governor.

WOOD-LIGHT MACHINISTS' TOOLS



IRON LATHES, PLANERS, DRILLS, BOLT CUTTERS, SHAPERS, ETC.

TREADWELL & CO., - - - MACHINERY DEPOT: Market, Head of Front Street, - - - San Francisco.

ASHCROFT'S Steam Gauges. The very best in the country. A large stock at reduced prices.

Nathan & Dreyfus' Self-Oilers and Cylinder Cups.

BARNES' Foot Scroll SAW. A nice hand machine in all small work.

TRADE PERIN MARK. Perin's BAND SAW Blades. TRADE PERIN MARK.

Belting

MUNSON'S BEST.

A Large Stock Always on Hand.

Our Upright Safety Engines Are the Best. All sizes.

For Sale only at TREADWELL & CO.'S MACHINERY DEPOT, San Francisco, Cal.

N. W. SPAULDING,
Saw Smithing and Repairing
ESTABLISHMENT.
Nos. 17 and 19 Fremont Street, near Market.

MANUFACTURER OF
SPAULDINGS'
Patent Tooth Circular Saws.
They have proved to be the most durable and economical Saws in the World.
Each Saw is Warranted in every respect.
Particular attention paid to construction of
Portable & Stationary Saw Mills.
MILLS FURNISHED AT SHORT NOTICE
At the lowest Market Prices.

The Best Injector
For Locomotive and Stationary Boilers.
FRIEDMANN'S PATENT.
Over 15,000 now in use here and in Europe. Throws more and hotter water, with less steam, than any others. It has two Waterways, fixed Nozzles, and no movable parts to get out of order.
TREADWELL & CO., Sole Agents, S. F.
☞ Send for Catalogue.

Every Mechanic
Should have a copy of Brown's
507 MECHANICAL MOVEMENTS,
Illustrated and described.
☞ Inventors, model makers and amateur mechanics and students, will find the work valuable far beyond its cost. Published by DEWEY & Co., Patent Agents and publishers of the Mining and Scientific Press.

SAN FRANCISCO, SATURDAY, NOVEMBER 13, 1875.

VOLUME XXXI Number 20.

Small Steam Engines.

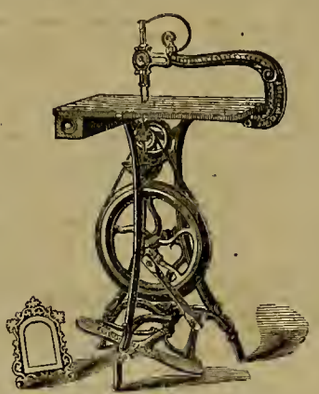
Mr. George Parr, of Buffalo, N. Y., who has spent many years in the construction of various useful tools, and especially small steam engines for light work, has constantly been making important improvements, and as a necessary consequence, has brought them to a high degree of perfection.

But the most important and useful step taken by him has been the manufacture of the different parts of small steam engines as rough castings, and their sale at low prices, so that each apprentice, young man, or even boy, who possesses a little mechanical skill, with the necessary simple tools, can easily trim and finish them without any assistance whatever. Mr. Parr thus confers a benefit upon all young men of a practical turn of mind, while many will be induced to try their hand at this pleasant as well as useful occupation. It is one of the most powerful contributions to the practical education of our youth, and Mr. Parr is so convinced of the usefulness and effectiveness of his attempts, and so willing to promote his liberal and enlightened views, that he offers to send his "Technical Guide" in most all practical trades, and which is illustrated with several hundred cuts of all kinds of tools and machinery, *free* to any young man who he thinks might be benefited by it, and even where a young mechanical genius may be awakened, also a set of these model engine castings free of cost.

We illustrate on this page three of these small model working engines. Fig. 1 is an engine and boiler complete, which is made in two sizes; the largest may be recommended as a useful and practical model, as it will drive a small lathe, scroll saw, or sewing machine; indeed, there are so many purposes to which an engine of this description might be applied, that it would be superfluous to enumerate them here. It is a horizontal slide valve engine and boiler. The boiler is of copper, and is on the vertical principle, ten inches in diameter and eighteen inches high, with steam cock, safety valve, two gauge cocks, glass water gauge, furnace and door. The cylinder is 1¾ inches in diameter, 2¼ inches stroke, connecting rod, parallel motion bars, solid forged crank, eccentric and rod, feed pump for boiler, iron fly wheel twelve inches in diameter, and brass driving pulley, planed cast iron bed plate on an imitation stone base. It may be had complete for $60, or the several parts unfinished at a lower price; the copper boiler costs $40, while the heating may be done by a spirit lamp or its equivalent.

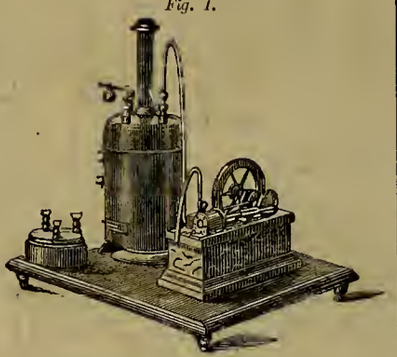
Fig. 2 represents a small working model engine, made in four sizes, the smallest of one-half inch bore and one inch stroke, the next of one inch bore and two inches stroke, and the largest of one and one-half inches bore and three inches stroke; while the complete set of castings of the smallest costs only $1, the largest, with its parallel guide-bars of brass, costs $4. Each of these sets will make the complete engine represented in Fig. 2. The castings for them are the delight of amateurs, as with very little trouble they may be wrought into the beautiful models herein described. Each part is truly proportionate, thereby rendering them, when complete, beautiful symmetrical models. They are all clean and well cast, and plain printed instructions for the guidance of purchaser will be sent with each set, and it is guaranteed that the most uninitiated will be capable of producing therefrom a good working model. They comprise the following pieces: cylinder, cylinder cover, cylinder bottom, piston, two stuffing-boxes, guide, slide valve case, two bearings, eccentric, eccentric band, forked connecting-rod, cross-head, driving-wheel, fly-wheel and slide-valve.

Fig. 3 represents a larger and more practical engine, for which the sets of castings may be had in three sizes—one and three-quarters, two or two and one-half inch bore, and three and one-half, four or five inches stroke. The engines made of these castings are compact, strong, powerful and economical, requiring no setting whatever, and are easy to manage; the iron is of the best quality and is highly annealed; the foundation plate on hollow tank, bearings or plummer blocks, two tops of the same, fly-wheel, driving-wheel, cylinder, cylinder cover, cylinder bottom, piston gear frame, two guide bars, slide-valve case, back of the same, two governors, piece for supporting the same, sliding cross-heads and eccentric are of iron; the force-pump, three glands (one each for cylinder cover), slide-valve case and pump, eccentric band, top of governor, top connecting-rod, and brushes for plummer-blocks are of gun-metal; two pulleys for governor, slide-valve, plunger for pump and throttle-valve are brass; the crank, connecting-rod, eccentric-rod, bed plate and cylinder are forgings.



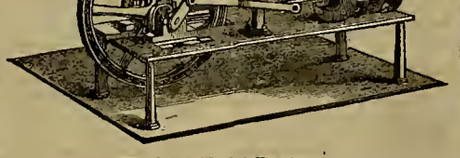
Small Foot Power Scroll Saw.

Fig. I.



Model Engine and Boiler Complete.

Fig. II.



Working Model Engine.

Fig. III.

Large Working Model Engine.

Battle Mountain.—C. W. Fraser, from Battle Mountain, informs the *Silver State* that things are pretty lively at the switch, and that the several mining camps in that vicinity are all turning out well. In Lewis district the Defiance company is putting up a fine mill. At Galena the Krom concentrator is working well, and the mines are producing a good deal of ore. In Bullion district the Eagle is proving to be a first-class mine, and Mr. Fraser thinks Battle Mountain is destined to become a great mining center, and as evidence of the faith that is in him, is building a brick store house, 30x100 feet, at that place.

A Bonanza.—Up to the evening of the 4th inst. bullion of the value of about $90,000 was recovered from the ruins of the Consolidated mill. The *News* says it is expected that this amount will be doubled when the work of clearing away the debris shall have been completed. A large quantity of quicksilver has also been recovered.

It has been found that varnish in the interior of safes generates an inflammable gas, which during the fire in Virginia City worked much injury to papers which might otherwise have escaped unscathed.

Scroll Sawing.

As scroll sawing is becoming popular as an occupation for amateurs by reason of the beautiful and practically useful results obtained, it may be well to remind them that, thanks to the inventive genius of the age, a machine has been invented which stands to ordinary sawing with a saw in the same relation as a sewing machine does to hand sewing with the needle. In the same manner that in the sewing machine the continual handling of the needle and necessary motion of the hand is superseded by the motion of a treadle with the foot, so in the scroll sawing machine the continual handling of the saw and the necessary motion of the hand and arm is also superseded by the motion of a treadle with the foot, while in both cases the hands are only employed to bring and hold the work in the right place.

We have on former occasions described various scroll saws, but they were all intended for the mechanical profession and for manufacturing purposes, and therefore large, heavy, and comparatively expensive; a small scroll saw, intended for amateurs as well as for small manufacturers, made by George Parr, of Buffalo, New York, has lately come under our notice, and we herewith give an engraving representing the same.

This machine, weighing sixty pounds and costing only $20, is claimed to do as much work and at less expense than any other scroll saw now in market.

It will saw at all times from one-fourth to one-half inch hard wood, and one-fourth to three-fourth inch soft wood, and has one inch stroke. The following articles accompany each machine, and are included in the price: One screw driver, one dozen saws, assorted, one wrench, one three-square file, handled, one oil cup and one belt to drive the machine with.

The Employees of the Consolidated and California mills were paid off the other day for labor performed during the month of October The pay rolls footed up the neat enm of $30,000. Notwithstanding the Consolidated mill has been burned down, the *News* says the pay roll for this month will probably be as great, if not greater, than last, as the force employed in rebuilding it is greater than when the mill was running.

The Woodville Mine Troubles.

We gave in our last issue a history of the Woodville Consolidated mine as drawn up by the investigating committee, and a very suggestive document it was. At the meeting at which the report was received a resolution was passed by the disaffected stockholders assessing their stock ten cents per share to defray expenses, and the meeting adjourned until the following Wednesday. Before that time, however, they were considerably astonished by the announcement that the trustees had levied an assessment of $1 per share, in the face of that very damaging report. As an instance of cheek this action stands pre-eminent, but unfortunately for the stockholders, no matter how much they may admire the cheek of the trustees, they must also pay the expenses.

Another meeting of the stockholders was held on Wednesday evening last. Mr. Hayes, of the investigating committee, said that no progress could be reported, as the committee had again been denied access to the books. He gave an account of the different shipments of bullion that had been made, showing how the receipts had fallen off under Pearson's management. He denounced the management as rotten and corrupt, and hoped Pearson and his whole clique would be brought to justice by the stockholders. Mr. O'Brien said there was no use of calling Pearson names. The only course to pursue was to take legal proceedings and bring the whole outfit into court. Mr. West was of the same opinion, and added as a consoling sentence that Mr. Pearson had been heard making the remark on the street that the present assessment would pay him, and then there would be another assessment of $1 to work the mine. As Mather, the new trustee, was in the room, he was asked to explain his action in proposing the assessment. He replied that he had been insulted at the last stockholders' meeting, and took what little revenge he could by proposing the assessment. A vote of thanks was immediately passed thanking Mather for his considerate action. Mr. Crossman stated that Woodville ought to be selling for $25 instead of $4, and that the mine was fully as good as that of Justice. He believed the stockholders ought to prosecute Pearson at once and without mercy. Mr. Hayes stated that the stockholders might expect a statement shortly from the present management, but it would be false. This assertion he made without a fear of contradiction. It could be proven in the courts. The committee were directed to commence legal proceedings against the management of the Woodville mine; a committee of twenty was appointed to collect the assessment of ten cents per share for necessary expenses.

The stockholders were very much enraged over the levying of the $1 assessment, and are particularly rabid over the fact that J. G. Mather, one of their own committee, had actually proposed the levying of the same. If present indications are any criterion to go by there will be a lively tussle before the assessment is collected. The stockholders mean to have the sale enjoined at once, and the trustees mean to have the money collected. And so the matter stands at present.

The Proposed Fire Launch.—A committee of the Board of Supervisors of this city has reported formally on the proposition to procure a fire boat. They think that the time has come when the protection of the water front and shipping demands the services of such a vessel. Besides this, it is well known that the water mains along the lower parts of the city are generally of a small size, and in case of an extensive fire are wholly inadequate. They therefore recommend that they be authorized to contract with Joseph Hepburn, mechanical engineer, to prepare the necessary plans and specifications for a steam fire launch, to throw six streams of water. The committee was authorized to make the contract at a cost not exceeding $100.

The new battery mill of the California mine, which was destroyed by the late fire, is being rebuilt as rapidly as the necessary material can be obtained.

Tunnel Law.

We copy the following letter from Wm. Teal to the Salt Lake *Tribune*, as the question concerning it is frequently asked, although we published the commissioner's decision at the time it was rendered: As the meaning of the tunnel law of May 10th, 1872, is still misunderstood, you would confer a favor on the mining community by publishing the following interpretation given to it by Commissioner Willis Drummond, in a communication to Hon. J. B. Chaffee, on Sept. 20th, 1872, and a decision recently rendered by the United States Judge, A. W. Stone. The first is as follows:

The line of the tunnel is held to be the width thereof, and no more, and that upon this line only is prospecting for blind ledges prohibited while the tunnel is in progress, and that the right is granted to the tunnel owners to 1,500 feet of each blind lode not previously known to exist, which may be discovered in such tunnel, but that other parties are in no way debarred from prospecting for blind lodes, or running tunnels, so long as they keep without the line of the tunnel as herein defined. The said line being required by our regulations to be marked on the surface by stakes or monuments placed along the same from the face or point of commencement to the terminus of the tunnel line aforesaid. When a lode is struck or discovered for the first time by running a tunnel, the tunnel owners have the option of recording their claim of 1,500 feet all on one side of the point of discovery or intersection, or partly upon one side and partly upon the other side thereof, but in no case can they record a claim so as to absorb the actual or constructive possession of other parties on a lode which had been discovered and claimed outside the line of the tunnel before the discovery thereof in the tunnel.

The following is the decision (on the main points) in Corning Tunnel Company vs. W. G. Pell, as reported by the *Mining Review:*

First—The line of the tunnel is the width of it, and no more.

Second—Tunnel owners, by virtue of this act, have the right of possession of all blind veins or lodes within 3,000 feet from the face of the tunnel on the line thereof: that is, all that exist within the actual width of the tunnel.

Third—That the right of possession to these exists independent of discovery in the tunnel, but the possession is limited to the width of the tunnel.

Fourth—That this right exists from the time of commencement of work and continues so long as due diligence in prosecution is maintained.

Fifth—When a vein is discovered, the tunnel owner's right is not circumscribed by the tunnel line, but is only limited by the laws regulating surface discoveries.

Eighth—Discovery must precede location. No mining claim can be located until the discovery of the vein or lode.

The foregoing are correct copies of both articles referred to. I would add that the interpretation given to the law by Commissioner Drummond has been sustained by subsequent commissioners.

Miners' Luck.—Miners' luck is illustrated by an incident of mining at Central City, Colorado. About two years ago two young men, with a joint capital of $400, were offered a half interest in a gold mine at Central if they would sink it 30 feet deeper. Upon each side were the Veto and other paying lodes, but these had good roads to the mills and furnaces of wealthy companies. Moreover, the mine was difficult of access; it was necessary to carry the ore in gunny sacks for a considerable distance; then to pack it upon mules: and thus by the time it reached the mills, the gold in it would not pay expenses. The young workers when they had spent all their ready money became discouraged and abandoned the contract. This year two new speculators came, and undertook to go on with the work upon the same terms. They had not sunk more than two feet in this abandoned claim when they struck ore worth $2,000 per ton.

The *Journal of Chemistry* warns the drinkers of water of wells near dwellings to beware of the typhoid poison, sure to be found sooner or later in those reservoirs, if any of the house drainage can percolate them. The gelatinous matter often found upon the stones of a well is a poison to the human system, probably causing by its spores a fermentation of the blood, with abnormal heat or fever. Wholesome untainted water is always free from all color and odor. To test it thoroughly, place half a pint in a clear bottle, with a few grains of lump sugar, and expose it, stoppered, to sunlight, in a window. If even after an exposure of eight or ten days, the water becomes turpid, be sure that the water has been contaminated by sewage of some kind. If it remains perfectly clear, it is pure and safe.

All the rats in the Ophir and Consolidated Virginia mines were killed by the gas during the late fire and not one is now to be seen in either mine. Rats take the same place in the mines that the Pintes do on top. They eat up the scraps of bread, meat, etc., that are thrown away by the miners, and which if left lying around would make the air very impure. Their presence is therefore a blessing, and it is very seldom that one of them is molested by any of the miners.

A Mining Company Held Responsible for Refusing to Transfer Stock.

Judgment has been rendered by Judge Morrison in favor of J. W. Winter and against the Belmont mining company for $1,200. The court found the following facts in the case: On the 24th of April, 1873, Winter was the owner of 150 shares of Belmont stock which stood upon the books of the company in the name of other persons, as trustees, but the certificates were properly endorsed. On the day mentioned, Winter delivered the certificate to W. R. Maurice, with permission to have the stock transferred to his name, to enable him to vote at the coming election. Maurice had the stock transferred to himself. He then endorsed the certificates as trustee, and gave them to Winter. On the 28th of the same month Maurice stole them from Winter, and on the 8th of May following he deposited the same with Poulterer & Verdinal as a margin for the purchase of 600 shares of the same stock. The next day these brokers sold in the ordinary way, to Woods & Freeborn, 100 shares of Belmont stock for $700 and delivered the stock deposited by Maurice. On the 10th of May Poulterer & Verdinal reported to Maurice that they had delivered his (as they supposed) stock to another party, but they would replace it. Woods & Freeborn obtained new certificates from the company upon the surrender of those issued in the name of Maurice. On the 3d of May Maurice sold to Lawrence Kilgour fifty shares of Belmont stock for $250, and this certificate was also transferred to another person on the books of the company. On the 14th of May, Winter, for the first time, learned that the stock had been stolen from him, and on the 21st he notified the company of his loss. At that time all the stock stood upon the books of the company in the name of Maurice, and it was not transferred until the 30th of July, 1873. On the 12th of July Winter tendered a bond of indemnity to the company and demanded a transfer of the stock to him. The demand was refused and a year ago this month Winter brought suit against the Belmont company for the market value of the stock subsequent to the demand. The court found the value to be $1,200, and gave judgment in favor of Winter, as before stated.

Lyon County.

Our patrons and the public generally who have identified themselves with the mines and mining interests of this end of the Comstock, will be gratified to learn that our Lyon county locations are just now receiving more marked and favorable attention in San Francisco than ever before. The statement is based upon numerous interviews with prominent stock dealers and mining speculators of that city within the past ten days by our associate editor, who returns from his visit greatly pleased at the present San Francisco complexion of Lyon county mining interests. Time was, not long ago, either, that it was only necessary to mention at "the hay" that a mine was situated below Gold Hill to have it sneered at as "wildcat" and worthless. For years the superstitious and foolish doubt has lingered with prominent speculators in that money center, that the genuine Comstock vein was cramped to the narrow confines of the now "bonanza" and Gold Hill mines. To remove this prejudice has taken theoretical as well as active, systematic work, it has taken years of muscle wear, the expenditure of much money, and the erection of powerful machinery for prospecting purposes. But it has been and is fast being removed. Stock operators and mine purchasers are beginning to have a doubt now to which end of the great lead will eventually prove the greater in the production of the precious metals, and no longer speak disparagingly of such mines as the Justice, Silver Hill, Niagara, Buckeye, Kossuth, Dayton, Amazon & Glasgow, Daney, Silver Central, and the many other prominent locations of this section.

Per contra, much interest is taken in the progress of the respective developments and a watchful eye is kept upon those most advanced in improvements. With the eagle eye of San Francisco capital constantly keeping tally of the good and adverse reports of these mines it needs but the "striking" (and clear demonstration of the fact) of a single vein of good paying ore on this end of the Comstock lode to place every prominent mine in Lyon county on the stock board at good figures. Does any one at all acquainted with the actual status of the mines that we have mentioned doubt that such a body of ore will soon be struck—if it has not been struck already? We do not at this time deem it wise to particularize more fully, than to say that it is our firm belief that each a body of ore to-day lies uncovered in the depths of at least two mines on this end of the Comstock ledge. Furthermore, we very firmly believe that the events of the next sixty days will place the stock of several of the mines in this county at figures that will astonish and gratify the most sanguine. With such a sure belief as this, we can but feel proud of our county's mineral wealth, and extend greeting to those who have labored so long and faithfully in bringing it about.—*Lyon County Times.*

The recent Government survey of Puyallup river, in Washington Territory, from the forks to its mouth, shows that by the outlay of a few thousands of dollars it can be made navigable for small steamers at all seasons of the year as far up as the month of Stuck river, and to a distance of twenty-five miles or more in the winter.

Grass Valley Gold Mining.

Grass Valley as a gold mining district is surely on the eve of a new prosperity. We are assured of this by all the signs of the times. We do not base our assurance on the old saying that "it is darkest just before daylight," although the darkest hour is just now upon this place, and we know that the light is promised. In Grass Valley district are hundreds of ledges of gold-bearing quartz, located years ago, and which have, to some extent, been worked. Most of these ledges assay well as to the gold they contain, but by "mill process" of working have not come up to anything like the production of gold that an assay promised. These locations on ledges are owned by men who have not the capital to erect expensive machinery for the mining and reduction of ores. The owners, however, have had faith in the future and have held on to their locations, complying in most cases with the law which retains titles. That future in which the ledge owners had the faith is about to be realized. A process is now on the eve of being perfected which will cause the most stubborn rock to give up its gold, and that process of reduction will enable the poorest miners to work ledges, although the capitalists stand aloof. We refer, of course, to the Fryer process. It has been tried somewhat and more than the greatest expectations of those interested in it have been realized. The process saves almost all the gold in the ore and is cheap to work and simple in its operations.

More than that we cannot say at the present time. When we reflect that the ores most easily worked by mill process, and with pans, concentrators and all such appliances, lose a large percentage of gold, the advantage of a process which saves even seventy-five per cent. of gold in a ledge can scarcely be estimated. It is believed, and within reason, that with all the perfection of mill machinery which Grass Valley at present enjoys, enough gold has floated down Wolf creek to pay a large part of the National debt. The new process stops the float and saves the waste. We are not saying these things for the purpose of writing up the Fryer process. There is no stock in the company for sale, and those who are backing the trial, now almost finished, have ample means of their own to carry on all experiments which they may design. So we say that with float rock here and obstinate ore that is rich, but which refuses to be milled to advantage, the new process is about to give life and vigor to this town of Grass Valley. Those who sit around and moan and groan at the hard times will be doing better by going out and driving down stakes on some ledges and then taking out some quartz to be put through the new works.—*Grass Valley Union.*

The Sewing Machine Trade.

It has been reported that several important sewing machine patents are about to expire. To ascertain what effect such an event would have upon the business, a *Tribune* reporter called upon the prominent men in several of the great sewing machine companies. The number of patents relating to sewing machine interests is large. Some have expired, and others are nearing the end of the term for which they have been issued. Nevertheless, there is a sufficient number of new patents being granted from time to time to more than counterbalance those that lapse. Inventors are continually discovering improvements, and those of any great value are caught up by the great companies, because they can afford to pay the highest price for such patents. The improvements generally are made by the workmen in different factories.

One of the members of a sewing machine company said that even if all the sewing machine patents were given up, and the right to manufacture thrown open to everybody, it could hardly pay any small company to start in the business. The large companies have made a reputation by a long and extended effort. A large expenditure of time and money would be necessary to reach any degree of success at all remunerative. The companies that might control large capital can use their money to a better advantage than in competing for a share of a trade that is now none too remunerative. The small companies would find themselves ruined before they could secure a trade. To make sewing machines so as to sell them at the present prices, the manufacture must be on a very large scale, and the experience necessary could hardly be bought. Many machines are sold to persons who expect to pay for them by their work. It is necessary that the installments should be small, and therefore the final realization of a profit is longer delayed. Under the present competition, where some agents seem anxious to sell as large a number of machines as they can, the interest on the capital expended nearly consumes the profits. Many of the companies are beginning to see this, and prefer to do a smaller business at better rates.—*N. Y. Tribune.*

A Last Resort.—President of a good assessment mine—How can we make $100,000 between now and spring? The stockholders won't stand another assessment.

Sharp Director.—Here, I have it; suppose we fall back on the mine and get out some ore.

President.—Capital idea. I'd forgotten all about the mine. I'll telegraph to the foreman to start on the pay ledge we covered up last fall. There's just as much silver there as there is in the pockets of the stockholders, but I hate the bother of working it.—*S. F. Ledger.*

Hydraulic Locomotive.

We made brief mention of this invention last week. Its origin is traceable to the introduction of flumes for floating lumber from the mountains to the valley. While the flume was and is, the cheapest transportation known for the purpose for which it was designed, the transportation of lumber, it served no other purpose. All the supplies demanded at the head of the flume, where the lumber was manufactured, had to be hauled there by teams. These flumes did nothing but transport lumber to the market. They transported nothing into the mountains; afforded no aid to travel. The flume lay along the mountain sides like a serpent basking lazily in the summer sun. The hydraulic locomotive is designed to make them serviceable in more ways than the one for which they were originally built. It is designed to travel up the flume, and it does it, too, at a lively rate. The steeper the grade the faster travels the locomotive. This may be in defiance of all former means for the transportation of freight and passengers, but the locomotive will do it nevertheless. The little wooden structure we saw on trial carried ten or twelve times its weight, and moved up a grade of about one foot to the rod at about half the speed that the current, one inch in depth, ran down the grade. Now, what the result will be when it is tried on a scale to be made serviceable for transportation of freight and passengers of course we are unable to say; but as a toy it is successful, for the little machine, weighing only a pound and a half or two pounds, carried ten or twelve times its own weight. The hydraulic locomotive is constructed with four wheels, and is designed to run on a track like the locomotive engine. The track is to be constructed on the top of the sides of the flume, which may be V shaped or otherwise. The motive power is the water passing through the flume. At either end of the car is a water wheel similar to that of stern wheel steamers. The wheels, like those of an ordinary car in use on our railroads, revolve with the axle. The axle, to which the wheels are attached, is made the shaft for the water wheel, the arms of which holding the paddles extend down into the water in the flume. The current of water in the flume furnishes the power to run the car. Of course the car must travel up the flume if it contains sufficient water to turn the paddle wheels. These paddle wheels are so arranged as to be unshipped when it is desired to run down the flume. As all flumes of this character must have a down grade, the hydraulic locomotive is supplied with brakes to regulate the speed on the down trip. We believe the hydraulic locomotive to be practical. Of course it will require a considerable volume of water to move a car of ten tons. This can be obtained near the head of Butte creek if it should prove desirable to have a flume to the timber of that region, and any volume of water necessary for one down Feather river could be had at the lower end of the Big Meadows. Of course the flume would have to be constructed with a view of having the track for the car on the top of its sides, and braced from the outside so that no ties or cross pieces would be required on the top of the flume, as that must be left open for the paddle wheels to work in. If it should cost as much to build a flume of this kind as it does to lay a railroad track the advantages would still be in favor of the flume, for the economy of motive power is much greater. Indeed, it is nothing at all after the track and flume have been constructed. It would also have the advantage of being narrow guage, which is an important consideration through a mountainous country. We hope the subject may attract the attention of capitalists and be given a fair trial.—*Butte Record.*

Riveted Joints.—The increased demand for plate and boiler work has stimulated scientific investigation, and brought out many facts of general interest. The value of a piece of plate work depends on the strength of the riveted portions. Calling the strength of an unpunched plate at 100, the strength of a double-riveted joint is reckoned at 66, a single-riveted joint at 50. Punched rivet holes, by means of the tearing and splitting caused by a smashing blow, are found to be less valuable by fifteen per cent. than drilled holes. Oval rivet holes have been tried with success. The long diameter of the rivet is placed in line with the length of the plate, thus reducing the space between the holes in its weakest direction. Sir W. Fairbairn suggests rolling plates with thickened edges, so that the line of rivet holes will be relatively stronger. This idea is now undergoing experiment. Boiler plates are also being riveted diagonally, with the joints at an angle of 45 with the axis of the boiler. As the relative strength of iron and steel plates is, iron, 50,000 pounds; steel, 60,000 pounds, many boilers are now being made of steel for the sake of this difference in strength.—*Scribner.*

Dull.—Pioche *Record*, Oct. 30: The monotonous cry of dull times meets us in every shape now-a-days in Pioche. People use and speak about it as if they rather liked the depression and where glad times were dull; this is especially so with those that have money and do not wish to pay, who screen themselves behind the expression "dull times." Times are dull and there are no doubts about it, but the cry of it eternally is the worst of the two. Such constant statement retards in a great measure the growth of better times.

SCIENTIFIC PROGRESS.

Phenomena of Earthquakes.

In the *Popular Science Monthly* for October there appears an article on the causes and other phenomena of earthquakes, by Professor Lake.

The Noises of Earthquakes

Are thus graphically described: Great subterranean noises and reports resembling thunder. These occur more or less during all earthquakes. Father Kircher describes them as "a horrid sound resembling that of an infinite number of chariots driven fiercely forward, the wheels rattling, and the thongs of the whips cracking." Sir Hans Sloane, in Jamaica, as "a hollow rumbling noise almost like that of thunder." At Colares, near Lisbon, in 1755, during the great earthquake, the sound is said to have been like "that of chariots, which increased till it equaled that of the roar of cannon;" and at Lisbon, "a rattling as of coaches in the street, with a frightful noise underground resembling the rumbling of distant thunder." At Madeira the same earthquake was preceded by "rumbling noises in the air like that of empty carriages, which died away like a peal of distant thunder." On the 16th of September, 1849, there was an earthquake at Burra-Burra, in South Australia, where the noise is said to have resembled the rolling of heavy carriages. This shock was followed by a flash of lightning that illumined the whole atmosphere.

The Effects of Earthquakes

Are vividly portrayed by Professor Lake. Another feature of the phenomena is the upheaval of the ground observed during the prevalence of most earthquakes, which is one cause of the sea retiring, another being the suction of the approaching wave when the center of the convulsion has been removed from the shore. During the great earthquake at Lisbon the bar at the mouth of the Tagus was laid bare by the upheaval, and the master of a vessel lying in that river at the time, stated that his large anchor was thrown up from the bottom, and seemed to swim on the surface of the water. Other results of the upward movement during this catastrophe were observed elsewhere. The water in a pond at Dunstal, in Suffolk, was jerked up into the form of a pyramid. At some places the water was tossed out of the wells. At Loch Lomond a large stone was forced out of the water. Rocks were raised into the air from the bottom of the Atlantic, and on board a vessel, about forty leagues from the island of St. Vincent in the West Indies, the anchors, which were lashed, bounced up, and the sailors thrown a foot and a half perpendicular from the deck, the ship sinking into the water immediately afterward as low as the main chains. At Riobamba, in South America, on the 5th of January, 1797, the bodies of many of the inhabitants were thrown, by this vertical action, upon the hill of La Culica, which is several hundred feet high, and on the opposite side of the river. During some of these convulsions in Italy, paving stones have been tossed into the air and found with their lower sides uppermost; and, at the time of a late convulsion in South America, the rising of the ground caused the sea to retire, which returned like a wall in appearance, carrying before it inland vessels that had only a few minutes before been left dry, towns and people being overwhelmed by the resistless recoil.

Vital Force.

"The prevalent opinion has until lately been," says Dr. Carpenter, "that this power, (vital force) is inherent in the germ; which has been supposed to derive from its parent not merely its material substance, but a *nisus formativus*, or *germ force*, in virtue of which it builds itself up in the likeness of its parent, and maintains itself in that likeness, until the force is exhausted, at the same time imparting a fraction of it to each of its progeny. In this mode of viewing the subject, alt the organizing force required to build up an oak or a palm, an elephant or a whale, must be concentrated in a minute particle, only discernible by microscopic aid, and the aggregate of all the germ forces appertaining to the descendants however numerous, of a common parentage, must have existed in their original progenitors. * * * * * And in like manner, the germ force which has organized the bodies of alt the individual men, that have lived from Adam to the present day, must have been concentrated in the body of their common ancestor. A more complete *reductio ad absurdum* can scarcely be brought against any hypothesis; and we may consider it proved that in some way or other, fresh organizing force is constantly being supplied from without during the whole period of the exercise of its activity.

"When we look carefully into the question however, we find that what the germ really supplies is not the force, but the directive agency." "The actual constructive force, as we learn from an extensive survey of the phenomena, is heat."—[*Carpenter, (Youmans,) page* 411.]

NEW PLANETS.—During the month of June last, three new planets were discovered, two by Professor C. H. Peters, Nos. 144 and 145 respectively, of the 11th and 12th magnitude, and one by M. Borelly, at Marseilles, No. 146, 11th magnitude.

Origin of Atmospheric Electricity.

According to M. Becquerel, solar spots, which are sometimes 16,000 leagues in extent, appear to be cavities by which hydrogen and various substances escape from the sun's photosphere. But hydrogen, which appears here to be only the result of decomposition, takes with it positive electricity, which spreads into planetary space, even to the earth's atmosphere and to the earth itself, always diminishing in intensity because of the bad conducting power of the successive denser layers of air and of the crust of the earth. That would then only be negative, as being less positive than the air. The diffusion of electricity through planetary space would be limited by the diffusion of matter, since it cannot spread in a vacuum.

That gaseous matter extends further through space than the distance which is generally assigned to the earth's atmosphere will be proved by the fact that auroras, which are due to electric discharges, are produced at hights of 100,000 and 200,000 yards, where some gaseous matter must exist.

M. De la Rive agrees with M. Becquerel as to the electrical origin of the aurora, but considers that the earth is charged with negative electricity, and is the source of the positive atmospheric electricity, the atmosphere becoming charged by the aqueous vapor arising in tropical seas. The action of the sun, he considers, is an indirect action which varies with the state of the sun's surface, as shown by the coincidence in the periods of aurora and sun spots.

In the accounts of travellers in Norway, we often read of their being enveloped in the aurora, and perceiving a strong smell of sulphur, which must be attributed to the presence of ozone. M. Paul Rollier, the aeronaut, who descended on a mountain in Norway 4,328 feet high, saw brilliant rays of aurora across a thin mist which glowed with a remarkable light. To his astonishment an incomprehensible muttering caught his ear; when this ceased he perceived a very strong smell of sulphur, almost suffocating him.—*Manual of the Natural History, Geology and Physics of Greenland.*

THE ORIGIN OF COAL.—The discovery of diatoms in coal, by Count Castracane, recently announced, is of much interest, as throwing additional light on the mode of formation of carboniferous coal. These minute forms of plant life have not been recognized in any but very modern formations; but Count Castracane has succeeded in showing that they date from the palæozoic epoch, as far back, at least, as the carboniferous period. He says: "All the forms I have been able to observe among the ashes of the coal present such an appearance that the most practised and sharpest eye could not detect the slightest difference between them and actually living diatoms: outline, structure, shape, and number of the flutings—in short, all the peculiarities which characterize the species that we meet with in the state of actual vegetation—agree exactly with those of the carboniferous period." It can scarcely be denied that the existence of these minute forms of aquatic vegetation in the substance of carboniferous coal goes to confirm the view of those who (like Professor Bischof) hold that this mineral has been formed in presence of water, and the great preponderance of fresh water forms of the diatomaceæ proves that this was fresh water; still the occasional occurrence of marine forms leads to the inference that the waters of the ocean occasionally had access to the lagoons or inland lakes.

In fine, the presence of diatoms, taken in connection with the stratographical phenomena of carboniferous coal beds, appears to bear out the views of those who hold that the mineral has been formed from the decay of successive generations of plants and forest trees, growing with their stems partially immersed in the stagnant waters of vast lagoons, these lagoons being nearly on a level with the waters of the sea, which sometimes gained access to them, and carried with them marine forms.—*Scientific American.*

COMBUSTION.—Some interesting facts have been communicated to the French Academy of Science, by M. Cailletet, who has been studying the phenomena of combustion. He finds, by means of an apparatus specially designed for the purpose, and in which he has been able to burn, not only a candle, but also a wick fed with alcohol, in highly condensed air, that the light gradually increases with the compression, finally becoming dazzling and so brilliant as to rival that of phosphorus in oxygen. But then, however, if the pressure be increased, the brilliancy of the light diminishes, the flame becomes smoky, and flakes of lamphlack are deposited. From this it is clear that the temperature of the combustion increases with the pressure up to the point of dissociation of the hydrocarbon gases of the candle.

A NOVELTY IN BRONZE.—German metallurgic science and ingenuity have resulted in a most beautiful novelty. It consists of a substance produced by fusion of gold, silver and platinum in small quantities, with bronze, with effects of color and luster which are described as gorgeously beautiful. It is cheap enough to be applicable to the embellishment of wood, leather, iron, etc., and much use may be expected of it in decorative art at no distant day. There has been a want of some metallic variety of hue and tone, especially for tints of purple. This elegant product completely supplies the want, giving a violet which is said to be quite indescribable.

MECHANICAL PROGRESS.

Chrome Steel.

The following is the paper on "Chrome Steel," read by General Carrington, of the United States Army, at the recent meeting of the British Association.

The report of the Committee on Steel invites a statement regarding the new alloy of iron with the oxide of eromium, which affords a steel having strength, ductility, elasticity, and uniformity unknown to the best of English or German steel. While the labors of Huntsmann and Heath made the crucible cast-steel to surpass old forms of blister and shear steel, the use of chrome is a still greater advance towards a perfect metal.

Chromium unites with the iron. It is a metal, while carbon is not. It has little or no affinity for oxygen, and is not affected by excessive heat. Such is the opinion of Capt. James B. Eads, engineer-in-chief of the St. Louis bridge. Its tensile strain is 198,970 lbs. to the square inch; while the greatest strength given in "Percy's Metallurgy," page 870, is 132,909 lbs. per square inch.

For forging it may be heated to almost a white heat without fear of injury; in fact, it is desirable that it be worked at a high heat, except in punching, which should be done at a mild heat. For tempering, the steel should be dipped at a low red heat, as shown in the shade. All tools forged from a large body to a small edge should be allowed to cool off after forging, and be reheated for tempering. The interior of the tool retains the heat at which it was forged after the exterior surface has cooled, and is too hot to put in the water for tempering, as it is liable to crack. For annealing, heat uniformly to a low red heat, and cover well in any of the usual annealing substances. For welding, heat, then lay the pieces together, and tap quickly and lightly, until they adhere, then gradually increase the blows until the weld is complete. To harden well is to harden at the lowest heat at which it will take temper.

A simple method for arriving at the proper heat for hardening is to place the end of a bar in the fire and heat it. Take it out, and note the different degrees of heat the whole length of the heated portion; then plunge into cold water. After cooling, break off a little at a time with the hammer, across the anvil. If the point of the bar has been too hot, the grain will show at first coarse and granular, gradually becoming finer, until you reach the point where the bar was heated to a dull red; and then the grain will be found fine and fibrous; and the steel harder, stronger and tougher than when the heat was greater. The point where the fine fibrous grain appears was at the proper heat when dipped, and that is the heat required for successfully hardening tools from chrome steel.

Exhaustive tests have been made of this steel in the United States, both at West Point foundry and at the Washington navy-yard. Chief Engineer Fithian, U. S. Navy, in a report to Admiral Goldsborough, states "that this metal performs three or four times more work than the best tools of carbon steel. It has uniform texture whether in large or small masses; it can be welded and worked with the same heat and ease that wrought iron can, and can be made into all the various forms required for machinery without danger of being destroyed by over-heating." The chromium is found as an oxide, and may be combined with ordinary iron, or with the Bessemer, and in all places and relations it gives a new and permanent value to the product. Toughness as well as hardness comes from graded heating, and it is submitted that the test of a large ingot by the manufacturers of large ordnance may lessen the weight of guns, while increasing their efficiency and safety.

CIRCULAR VS. BAND SAWS.—The German industrial papers are discussing the question of the disadvantages of circular saws as compared with hand saws: 1st. Circular saws are very dangerous to the workmen. 2d. They require a much greater power to drive them than any other kind. 3d. They make a much wider cut, producing more waste, and thus fewer products from a given amount of material. The only advantage is, that the first cost of procuring a circular saw is less than that of a hand saw; but, notwithstanding, the Mechanics' association of Mnehlhausen have already published in their yearly report the advice to abolish their use wherever it is practically possible to do so; and this is of course the case in a great majority of circumstances.

STEAM STREET CARS.—Mr. Baxter, not satisfied with his triumph on canal propulsion, has essayed that of street railroads. A Baxter steam street car is being tested in Philadelphia, upon one of the suburban horse railroads, and if satisfactory, it is proposed to adopt it generally upon all the lines. Some adaptation of steam power appears necessary upon our street railways, and that named is at present the most practicable, says a Philadelphia exchange.

METAL GLASS.—Another hard glass, to which the above name has been given, has been produced at Buntzlau, Germany. The tests withstood appear to be about the same as those to which the Bastie glass was subjected, with the exception, however, that the metal glass is indifferent to cold water when highly heated. Bastie glass breaks under similar conditions.

Substitutes for Steam.

It is known that the expansion of liquids by heat takes place with such force that practically it may be considered irresistible, while vapors being elastic, any resistance causes compression; it is true that the expansion of a liquid into a vapor causes an expansion many hundred times equal to the volume of the liquid, and that the expansion of the liquid itself by heat is very small; but in compensation for this the force developed is enormous.

This is now being applied to develop power, and experiments made in London, in which either oil or glycerine is made to perform the functions of steam by the same means—the application of heat—have excited no small interest. The heat expanding the oil placed in small cylinders, a pressure of 10,000 pounds per square inch may be obtained without the danger of steam explosions, which latter prevents the use of a pressure of more than 200 pounds to the square inch generally. In this instance an explosion would only crack the cylinder containing the oil. The application of this process appears, from the accounts published, to have been successfully made to the printing press and to machines for riveting and punching, and it is alleged that the variety of uses of which it is susceptible will be found very great.

It is known that the rapid motion of a steam piston may, by gearing and belting, be made to produce a very slow but powerful motion over a very small space, able to punch and cut iron plates otherwise requiring tons of pressure to penetrate, and it is equally evident that this operation may be inverted, and that a low and very powerful motion over a small space (as is obtained during the expansion of liquids by heat) may, by gearing and belting, be made to produce as rapid a motion as is obtained by any steam engine.

A REFLECTOR FOR MOLDERS.—A reflector for the use of molders in pouring metal is manufactured by Messrs. Jackson & Tyler, No. 16 German street, Baltimore, Md. All molders have felt the inconvenience of being compelled to pour off metal in the imperfect light of winter or dark afternoons. This difficulty, which may be said to exist more or less from October to the spring, materially retards labor, and in large foundries is a source of considerable loss to the proprietors. The reflector obviates this difficulty without cost for illumination. A concave disc of nickel plate is placed upon the ladle handle, and throws a strong light from the molten metal directly over the ladle nose upon the sprue hole. The molder is thus enabled to pour into the flask without danger of spilling the metal or allowing it to strike the sides of the hole, by which contact the metal is unnecessarily cooled. This device is easily and quickly adjusted. The eyes of the molder are shielded from the intense light and his arm protected from heat, which considerations are valuable as facilitating his work; and his ability to pour rapidly and without hesitation and guesswork, achieved by the use of the reflector, give the reflector a practical value which merits attention.

JOINTS IN CARPENTRY.—Professor Rankine sums up the principles, which should be adhered to in designing joints and fastenings in carpentry, concisely as follows: 1. To cut the joints and arrange the fastenings so as to weaken the pieces of timber they connect as little as possible. 2. To place each abutting surface in joint as nearly as possible perpendicularly to the pressure which it has to transmit. 3. To proportion the area of each surface to the pressure which it has to bear, so that the timber may be safe against injury under the heaviest load which occurs in practice; and to form and fit every pair of such surfaces accurately, in order to distribute the stress uniformly. 4. To proportion the fastenings so that they may be of equal strength with the pieces which they connect. 5. To place the fastenings in each piece of timber so that there shall be sufficient resistance to the giving way of the joint by the fastenings shearing or crushing their way through the timber.

A NOVELTY IN WATER PROPULSION.—A new Haven (Conn.) mechanic, has invented, and is said to have recently successfully tried, a new thing in water propulsion, not for speed, but for economy and for progress without "wash," adapting it especially to canals. He has a boat with two keels—these are parallel—an air-tight box being fixed between them. Air, compressed to the degree of three or four atmospheres, by a small steam engine, is introduced through this box to the surface of the water. The emission of the compressed air resisted by the water, and confined between the parallel keels, operates to propel the boat about five miles an hour without commotion of the water.

A 70-TON STEAM CRANE.—An immense steam crane has lately been set up at the Victoria Basin, Dundee. It is nominally a 70-ton crane, but the test load is 90 tons, and the makers have no fear of putting 100 tons on it. It has already carried 80 tons, lifting that load with only two-thirds of the allowed pressure of steam, and lowering on the brake with a nicety that would enable the most delicate adjustment of its load, in case of its being used in erecting marine engines, to be made with confidence. The crane will deposit its load a clear distance of 40 ft. from the face of the quay wall, or 56 ft. from the center of the pedestal of masonry on which it is fixed, and the head of the jib is 60 ft. in perpendicular hight from the coping of the pedestal.

The Mining Share Market.

Mining stocks during the past week have been inactive; sales are few and prices ountinne low, showing however, that it is difficult to get them much lower than they are at present. During two days of the week the San Francisco Stock and Exchange Board adjourned its sessions on account of the death of an old respected memher of the Board, B. F. Sherwood.

Contrary to the expectations of the "oroakers," Consolidated Virginia announced the regular monthly dividend of $1,080,000, a nice little sum to distrihute at this season of tight money markets. The scarcity of coin prevents much speculation in mining shares, and hnsiness for the brokers is therefore dull. Advices from the Comstock are contradictory in their character, hut everything possihle is heing done to hurry up the repairs to the injnred works, and hefore many weeks everything will he running as hefore. An article in another column will give an accont of what is now heing done on the Bonanza mines at Virginia.

An era of investigation among mining companies appears to have set in and some of the developments made in the companies are "richer" than those made in the mines. The indications are that stockholders are hecoming aronsed to the fact that they have something to say as well as the trustees, and if the latter do not act right they can he tnrned out. Some acconnt of the different investigations now going on will he found in another column. We regard the movement as a very good one, and sincerely hope that the stockholders will drive all the irresponsihle and dishonest trustees out of the society of decent men. A few examples would serve to. porify matters considerahly; and it is to he hoped that those who have begun this war will keep it np to the hitter end, and show that they have some rights and will msintain them.

REDWOODS RAILROAD—The Sonoma *Democrat* says: E. C. Rust called npon us on Monday. He has been engaged on the snrvey of the railroad from Fulton to Gnerneville. The survey is in charge of J. C. Des Granges, of Oakland. Bnt little grading is required on the road. The greatest degree of curvatnre is seven, and the heaviest grade is 47.100 of a foot in the 100 feet. The work on the road will he continued as long as the weather will permit. Mr. Rust informs us that the track on the railroad is laid to the Laguna bridge. The road is graded one mile heyond the hridge. The spiles for the bridge have all been driven, and they are waiting now for the stringers, which are of Oregon pine, and must he shipped from San Francisco. There is no difficulty whatever on the route, and the work will continne with all possihle dispatch nntil it is completed.

WATEB IN THE DITCH.—Calaveras *Chronicle* says: The rains have increased the water in the ditch to nearly its full carrying capacity. It is not prohahle that there will he any further scarcity this season, and there is now nothing to prevent miners from pntting on their gum snits and wading in. Even if the resnmption of mining operations don't make things livelier, it is at least a relief to know that we haven't got to endure any more growling ahout the scarcity of water for a season.

ROADS.—The roads are in splendid condition. No dust, no mnd. Teamsters are happy and there is no language strong enough to express the felicitons condition of stage drivers.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

WASHINOTON BLUE GRAVEL CO.—Nov. 5, Location Mount Pleasant district, Sierra county. Capital stock, $22,000, divided into 22 shares of $1,000. Directors—J. Rey, Henry Steinegger, J. Gantner, P. E. Croce and Lnis Jnri.

PACIFIC WOOD, LUMBER AND FLUME CO.—Nov. 9. Object: To cut and manufacture wood and lnmber, and flume the same; also, to hny, sell and trade in real estate. Capital stock, $500,000 in 1,000 shares of $500 each. Directors—James C. Flood, Wm. S. O'Brien, J. W. Mackey, Edward Barron and Geo. Wallace.

COLUMBIA G. & S. M. CO.—Nov. 9. Location: Tuolumne county, Cal. Capital stock, $5,000,000, in 50,000 shares of $100. Directors—Frederick Clay, J. W. Tburman, A. M. Starr, R. von Pfister and James Meabrum.

SIERRA FLUME AND LUMBER CO.—Nov. 10. Object: Conducting a general lumber business in the State of California. Capital stock, $10,0.0,000. Trustees—W. P. Chipman, Benj. Peart, Walter S. Hobart, A. H. Rose and Chas. E. Elliot.

PACIFIC STEAM TRANSPORTATION CO.—Nov. 10. Object: To carry on a general commercial and transportation business on the Pacific and Indian oceans, the China seas, and all tributary waters. Directors—F. W. Jones, P. R. Irwin, S. P. Beach, H. A. Kimball, and F. Chappellet. Capital stock, $500,000, divided into 5,000 shares of $100 each.

Mining Company Elections.

The following mining companies have elected officers for the eneuing year:

JOSEPHINE CONS. M. CO. Trustees—A. K. Grim, President; D. L. McDonald, Victor Fernhach, W. F. Leon; O. H. Bogart, Secretary; W. F. Leon, Supt.

HOWARD HILL G. M. CO. B. A. Becker, President; Chas. Staempfli, A. Eberhart, J. W. Wesson, and W. A. Ray, Trustees; A. E. Kennedy, Superintendent; F. J. Hermann, Secretary.

LADY-BRYAN M. CO. James Phelan and P. Connolly have heen elected trustees to fill the vacancies caused hy the resignations of Wm. McClintock and John F. Boyd.

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in the Mining and Scientific Press and other S. F. Journals.]

MINING SUMMARY.

THE following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALAMEDA.

LIVERMORE COAL MINE.—Alameda *Encinal*, Nov. 6: The works of the Livermore coal mine are ahont completed, and the company will soon commence the shipping of coal to the people hereahout.

AMADOR.

QUARTZ MILLS RUNNING.—Amador *Ledger*, Nov

LENCOE CONSOLIDATED MINING COMPANY.—Glencoe Consolidated mining company, a nt incorporation, have acquired possession he well known Lewis & Fairchild and Ash- l mines, in the Mosqaito district, and are paring to work them exteasively. The es mentioaed adjoin sach other on the e vein. Considereble work hss been done the Lewis & Fairchild, the ore extracted ding very large retnrns A shaft hss been k to a depth of ebont 70 ft and levels run, overiag one of the most promising ledges in eastern portion of the conaty. Compsra- ly little work has yet boen done upon the land. It is the intention of the new pro- tors to prospect the vein nntil the proper s for sinking a main shaft can be de- ined, and then erect snbstantial machinery siak to a depth sufficisnt to thoroughly test permanency and vslne of the lode. F. cher, Esq., an experienced nnd practical er, whose loag connection with mining op- ions in the npper country has rendered him ectly familiar with that esction, is to be erintendent of the mine. The company n business, and they certainly could not e selected a more favoreble locality for the elopment of a successfnl mining enterprise n the one thsy have chosen.

LENCOE DISTRICT.—The lower stopes of the Bruno are now yielding larger quantities re than expected, and the glittering of the ions metal leavee no donbt as to the valae. mine will require heavier machiaery in a t time. Very rioh ore has been struck in tunnel of the Joaqnin. A winze ie now g sunk to ascertain the extent of this body. Matters at the Rickman mine are factory. The machinery for the Grass- per is on the ground and will he pnt in ition ae aoon as poesible. The previone kings of the mine realized ore worth $147 ton. To judge by the yield of the ore recently hed, and general outlook of the mine, Pot- & Co. will make a fine showing in a few nths.

DORADO.

HE WOONSIDE.—El Dorado *Republican*, Nov. The ore at the Woodside continnes to look L. Improvemente are being made which enable them to extract the gold from the pharets usually let go to waste, and it is ght that enough can be realized in this way o vsry far toward paying the rnnning ex- ses of the mine. The running of an in- e from the present hoisting works to the e now being worked throngh a shaft 240 deep, and a tunnel 130 feet in length, is emplated, ae is also the addition of five e stampe. From the two olean-ups made ding the peat month, with five stamps, $4,500 e sent below. Twenty-two men are em- yed about the worke. With one or two hdred feet more depth we may expect to r of extraordinary rioh developments in the Voodside.

HE failure of the bank of California cansed saepension of negotiations nearly conenm- ed for the reopening of the St. Lawrence e, and the disastrous fire at Virginia will doubtless delay the project for some time. is ie to be regretted, as we believe that the e will prove a very profitable property if roaghly and economically worked, and give mene nt employment to a large number of n.

r ie rnmored that the Cederberg mining cpany are negotiating for the purchaee of Taylor mine, and that it is probsble that it l be sold to them. The Taylor continuee to k fine, and has every indication of being manently rich, but the machinery now in , we are told, is inadequete for the require- nts.

PA.

PAONUCT O F POPE VALLEY MINE.—Napa *Re- ter*, Nov. 6: The totnl produot of the Pope ley qnicksilver mines, so we learn from a gleman well qualified to know, has been, n the first to the presont time, about $345,- 0 worth of quicksilver. This represents a ch larger qnantity than present prices would icate, a large portion of the metal having at t been sold under contract at 45 cents per nnd.

VADA.

PROVIDENCE MINE.—Nevada *Transcript*, Nov. The owners of the Providence mine have, ce Jnly, been performing dead work moet of time, in the best part of their mine. They ve opened up new levels, stripped the ledge d left the rock ready to be taken to the eur- e when the proper time comes. Enough k hae been taken out of the other parts of mine to keep the mill running, but the onanza" portion is awaiting the completion Fryer'e works. A mining expert from San ncisco, after examining another mine upon ich he is to report, visited and paesed ough the Providence last week. We are in- med that he eays he never eaw ae pretty a ht in all the mines he ever visited. The k which lies exposed reedy to be taken out rich in sulphnrete and galena, and it glistene e fire as the lights shine upon it. The de- sit is very large, and by mill process will pay into the hundreds per ton. It ie intended work it all by the Fryor procese.

NEW YORK HILL.—*Foothill Tidings*, Nov. 6: ws from this mine is of a very favorable racter. The ledge is large and the rock of d quality. The yield of the mill for Octo- was about $19,000, a nice little nugget for omparatively new mine. Jamee Champion s recently been appointed underground nager of this mine—a most excellsnt choice.

FRYER'S PROCESS is declared a perfect sucoess, and the capitalists who backed Mr. Fryer in his undertaking to establish works here have returned to the Esst, satisfied to let the fntnre rest upon the praotical doings of these works. Mr. Fryer has, we understnnd, purchased the Glenhrook property, npon which the works are situated, and while intending to erect other works for all who wish them, will run these on custom rock.

RANDOLPH FLAT and vicinity is a fine field for the prospector nnd we hope to see many new mines opened there soon. Egan & Co. are nt work on Raudolph hill and we should jndge are tsking out good pay from their mine. We were shown a nice lot of coarse gold this week, and the boys seem to be in the best of spirits. Reese & Co. have been compelled to suspend work for the winter, on noconnt of water, but hope to he able to start in good shape in the spring. Reese is at present prospecting some new locations, with good promise of success.

KENTUCKY.—We saw some good looking quartz from the west drift this week and understand that the men who own in and also work in this mine are very much eleted at the wey the ledge is improving in that direction. The mine is only half a mile from Fryer's new reduction works.

PLACER.

NEW COMPANIES.—Placer *Argus*, Nov. 6: The work of developing the mining resoaroes of Placer oounty goes forward with vigor. Nsw minss, both quartz and gravel, are opened every week, and the production of the precious metals ie conetantly increneing. Great activity is displayed all over the county in preparing for the coming eeason. Should it be a favorable one, as now anticipated, a prosperons year is before ns. Within a week two new companies have been organized to work gravel mines in this county, both by San Francisco capitaliste.

SONOMA.

COAL.—Sonoma *Democrat*, Nov. 6: We are informed that quite a promising outorop of coal wae strack in grading for the railroad to Guerneville, on Jacob Jacobson's ranch, on Russian river.

STANISLAUS.

COAST RANGE QUICKSILVER MINES.—The *News* eaye that prospecting for qaicksilver in the Coast range, in Stanislaus county, is being pushed ahead with considerable activity. The editor has been ehown samples of ore taken from the Cristimba olaim ranging from 40 to 80 per cent. of mineral. These samplee are found at a depth of abont 30 ft from the surface. The vein containing qnicksilver is represented as being 4 ft in thickness, in only about 4 inches, however, of which the highest grade ore is found, the other portion containing a small per cent. of qnicksilver. From indications, those in charge of the works are sanguine that they will soon open out on to a solid body of splendid ore. Covert & Co. are still at work on the Waterford mine. They have already one furnace in operation. They have made trial tests, and are now confident that they can smelt out quicksilver sufficient to defray the expenses of developing their claime. These men are praotical; they own the greater part of their claims, and work the mines themselves. The other day they succeeded in retorting 2 tanke of quicksilver, which is, indeed, very encouraging to them, and causes all to hope that they will yet he rewarded for their indnstry and energy.

TRINITY.

ON THE ROAD.—Trinity *Journal*, Nov. 6: The large retorts for the Altoona quicksilver mining company reached the Davis ranch this week. Owing to the bad condition of the roads, oaused by the late rains, it is probable that they cannot be moved from there for a few days, but the oompany intende to get them to ths mines hefors another storm.

MINERS are all getting ready for the sluicing season, and town is distressingly dull. Of conrse we are sure to have a wet winter this time, so we are resting contont in expectation of the good time coming, when the boya clean up, next spring.

TRINITY Q. M. CO.—Mr. J. W. Smiley returned this week from Cinnabar, where he has been for the past fortnight, prospecting the depoeit in the Trinity company's mine. He reports the etringer to be 24 ft wide, and it hae been followed more than 100 ft in longth. The oompany havo contracted with Samuel Eggers for a new tuunel, 300 ft in length, which will tap the deposit about 100 ft below the present tunnel. Through this lower tunnel they will work next summer, by whioh time they expect to have furnacee erected and everything in order for the reduction of ore. At present the company hae some fifty tons of rich ore on their dump, taken from the upper tunnel. Smiley eays they have one of the higgest thinge in the world, and his judgment on mining mattere is oonsidered sound.

TULARE.

MINERAL KING DISTRICT.—Tulare *Weekly Times*, Nov. 6: We hear good reports from Mineral King mining district, although the work has nearly suspended for the season, owing to the inconvenience of getting in enppliee, the district being far into the mountains without a road and a large quantity of snow falls dnring the winter. Mr. G. W. Brown, the superintendent, and J. P. Ford, the recorder of the district, called on us this week, and both are confident of a great development of the mines next year. We learn from them that the company working on the White Chief are cutting down on the lead by beginning on the lower sids and makiag a cut through toward the hanging wall. They have advanced eight ft into the lead and have exposed a solid mass of galena ore 16 ft high, which assays from $112 to $220 per ton. It is believed thst the lead is 30 ft thick. The company is still at work, and will go down 30 or 40 ft on the ore this fall. Considerable work has been done on the Lsdy Frenklin lead during the summer. A tunnel has been run into ore for about 30 ft, and shows a solid vein of ore 7 or 8 ft in thickness, which assays from $50 to $150 in silver per ton. Extensive work has heen done on the Silver Wreath, McGinnis and Empire, all of which show a good development of well defined ledges of ore which assays from $50 to $500 per ton. It is a sottled question es to the smount and qnality of ore in the district; and the next move will he to erect mills and smelting works; bnt in order to do this a road is almost absolutely necessary. We expect to see a quantity of bullion coming out of this district by another year.

Nevada.

WASHOE DISTRICT.

JULIA.—Gold Hill *News*, Nov. 4: The main sonthwest drift, on the 1400-ft level, is advancing seven feet per day, the face in quartz, porphyry and ore mixed, of the most favornble description. There ie every indication that perhaps the next blast exploded will discover the main ledge and bodies of pay ore. The drift at the 1500-ft station ie in twenty-six feet, the face in the fine appearing material. The bottom of the shaft ie also in qnartz and porphyry of a fine, promising character. Work is being driveu at all points energetically, and the prospects of the Julia are growing more enconraging every day.

PROSPECT.—Fine looking streeks of qnartz are being out through by the tunnel, all of which give good aseays.

BELCHER.—The pumps are running steadily and the water is almost entirely extracted from the 1600-ft level, ready to again commence cross-cutting in that portion of the mine. Everything in and about the mine is working splendidly, and new life appears to be infused with the inoreased extraction of the amount of ore.

CHOLLAR-POTOSI.—Daily yield, 60 tone of ore. Thie ore is being extraoted from the old upper workings, which show bnt little change in any of their features. The main south drifts on the 1250 and 1350-ft levels are steadily advanoing. Sinking the new oombination shaft ie making excellent progress, the rock in the hottom blasting out finely.

YELLOW JACKET.—The north drift from the bottom of the eouth winze on the 1940-ft level ie in a distanoe of 26 ft, and the eouth drift from the bottom of the north winze on the eame level is in 56 ft, the faoe of both in good running ground and perfectiy dry.

NORTH CONE. VIRGINIA.—The work in this mine is still confined to einking the main shaft, no croes-cutting having as yet heen attempted. When a good and sufficient depth is attained, several levels can then be opened and prospected in the same interval of time that it wonld take to prospect one.

IMPERIAL-EMPIRE.—The ore breasts continne to look well and yield ahont 40 tons per day of good milling ore. Everything working finely both in and about the mine. The Kelsy mill at Silver City was started up on ore from the mine during the week.

SAVAGE.—But little has been done in thie mine during the past week, except to pump and hoiet water. The water hae been lowered in the incline 175 ft during that time, showing thnt the flow ia gradually subeiding. It will not now take long to drain the main incline, when work can be resumed successfully at all points.

SUCOOR.—The rock in the faoe of the west croee-cut is much softer, with streaks of quartz and ore coming in, furnishing strong indications of a near approaoh to the main ore vein.

OVERMAN.—The main west drift on the 1100-ft level is rapidly advancing. The south drift from the bottom of the winze on the 1100-ft level is steadily advancing, the face in soft material.

DAYTON.—The work in the mine is mostly confined to sinking the main ehaft at a very rapid and encouraging rate. The new maohinery worke with the utmost perfection, and there is little or no trouble occasioned hy the flow of water.

BEST ANU BELOHER.—Everything ie agnin in good shape, and the prospecting on the 1700-ft level ie being vigorously prosecuted as usual.

ROOK ISLANU.—Driving the main weet drift on the 550-ft level is making steady progress, notwithstanding a steady flow of water that keepa the pumps pretty busy.

SIERRA NEVADA.—Sinking the shaft making good headway. The west drift on the 1000-ft level of the new shaft ia stendily advancing, without change of valne.

SILVER HILL.—Sinking the main incline below the fourth station level is making steady and favorable headway.

BALTIMORE AND AMERICAN FLAT.—Sinking the main incline is making rapid headway, the rock in the bottom blasting out finely. No water to interfere.

MINT.—Sinking the shaft as usual, the bottom in very favorable ledge material. Tho shaft is now down 900 feet.

BUCKEYE.—Sinking the mnin inclius is making favorable progress. The flow of water is quite strong but is easily handled by the new pump.

LAUY BRYAN.—Sinking tbe shaft is going ahead as usual. The southwest drift, on the 170-ft level, is in 212 feet, the face in quartz and porphyry, mixed with occasional streaks of fine ore. Cross-out No. 5, on the 250-ft level, is egain being driven ahead, the face showing some fine ore. On the 380-ft level the main north drift is in a distance of 195 feet, following the east wall of the ledge. The main sonth drift on the 380-ft level is in 430 feet, the face in white qnartz, strongly resembling the heavy hodies of qnartz fonnd in the Ophir, Consolidated Virginia and other Comstock mines.

LEVIATHAN.—Since last week's regular report the north drift at the 420-ft lovel has rnn into a rich ore body, which is believed to be extensive. The whole fsce of the drift to-day is in rich ore, assaying up in the hundreds. This development is not unexpected, as the drift has been running for it all the time, and the same rich vein shows in the level above. When it ie cross-cut into, its width can be aecorteined.

UTAH.—The putting of the pumping machinery in good working condition is being done as fast as it is possible for it to be accomplished by foundrymen and machinists.

CROWN POINT.—Deily yield 300 tons of ore. The ore breests continue to look well and yield the nsual amount of milling ore. The Mexican mill will be also started np on ore from the mine as soon as the repairs are completed, which will be ahont the middle of November.

CALEDONIA —The dowaward progress of the shaft is about three feet per day. The pump tank etation at the 505-ft station is abont completed.

GOULD & CURRY.—Work in the mine was discontinued on account of the conflagration and flood of water from the Consolidated Virginia last week. The water has been almost entirely drained, the pump handling the flow with the most perfect ease. The lower levels have been greatly cooled and benefited by the flow of water, and work has again been resnmed at all points to a better advantage then before the flood.

GLOBE CONSOLIDATED.—The south drift from the main west tunnel, in the ore vein on the adit level shows it to be from fifteen to twenty feet in width, with spote of excellent ore. The north drift on the ledge at the 350-ft level is etill in quartz, cutting in its course fine bunches of ore.

LEO.—The work of driving prospecting drifts from the hottom of the winze is steadily going on. Drifts are still in a very favorable character of ledge matter, showing seama of good-looking quartz. Ledge large and well defined, with casings emooth and regular.

AMAZON ANU GLASGOW.—The shaft is down 350 ft, at which point a station is being opened and a drift eterted to cnt and prospect the ledge, which is not only well defined at thie point but promiees to prove itself a valnable ore deposit.

NEW YORK CONSOLIDATED.—The new machinery continues in splendid operation, draining tha shaft very effectually. The prospecting and development work of the mine will be proceeded with actively and nnder the most favorable auspicee, as one excellent seam or vein of quartz asseying $50 to the ton is already enoonntered.

SOUTH COMSTOCK.—Excellent progress is being made with the cross-cut, which is in a little over 200 ft to-day. The face is in qnartz and clay seams, and pushing at right angles across the ledge matter toward the msin ore vein.

JUSTICE.—Streaks of low grade ore continue to he met with in the south drift at the 800-ft level, ehowing nearer proximity to the main ore vein. The 500-ft level is showing still better than last week, the face of the drift continuing in fine ore.

WOOUVILLE CONSOLIDATED.—Work on the new building and machinery is making good progress at all pointe. The face of the drift on the 426-ft level is in quartz and porphyry mixed.

WEST BELCHER.—The main tannel is in 315 ft, the face in qnartz of a fine character, from whioh excellent aseays of gold and silver are obtained.

FLORIDA.—The west drift has tapped a stronger flow of water from the winzes, which are now draining oat fast.

NORTH CARSON.—A good promise for a rich mine ie being made by the indications in both the upper and lower tunnels.

SULLIVAN.—The sinking of the new ehaft, and advancement of the drift, progresses nt a satisfactory rate; both in vein matter of a most promising and encouraging character.

CALIFONNIA.—Men are again at work on the 1550-ft level as usual, the neceeeary hoisting being done through the Gould & Curry shsft. The face of the main north drift on the 1550-ft level is being steadily advanced toward the north line, the face still being in rioh ore. Sinking the winze below cross-out No. 5 on the 1550-ft level ia making good headway, the bottom also in rich ore. Sinking the C. & C. shaft is being pushed forward with all the vigor possible.

LAUY WASHINOTON.—Both pumps in full working condition. Shaft entirely freed from water and easily kept so. Sinking is resnmed to-day under the most favorable auspioes. The ponderons new machinery is working right straight along, moving easy and smooth, and with the regularity of olock work.

NEVADA.—The winze below the east oross-cut from the south drift at the lower level, is being sunk at a satisfactory rate, following a streak of low grade ore, in search of something better.

COSMOPOLITAN.—Face of main tunnel all in good milling ore.

CRIONAL GOLU HILL.—South ore body showing more extensive as further developed.

VIVIAN.—Grading new road to the miue, and also grading for hoisting works.

Micro-Mineralogy.

At a recent meeting of the San Francisco Microscopical Society, Mr. Henry G. Hanks, the well known chemist and assayer, read the following paper on micro-mineralogy:

In a scientific sense, the word "mineral" used as a noun, implies any inorganic substance having a uniform chemical composition.

As an adjective, it may also denote a mechanical mixture of two or more minerals, as for example, granite, which may be called a mineral substance in contradistinction to animal or vegetable substances. Granite is composed of quartz, feldspar and mica, each of which are minerals in the first sense. The constituents of granite are often so finely divided as to deceive the unassisted eye, and to appear homogeneous. This is frequently the case with ores, which are also aggregations of minerals.

As a rule, crystals are pure minerals, although the rule is sometimes exceptional, as in the case of arenaceous limestone, resinous fluids in quartz and topaz, specular iron in feldspar, chlorite and titanic acid in quartz and other examples. If a mineral be a pure species, an analysis of one portion will give the same result as that of any other portion. The practiced eye of the mineralogist detects at a glance any of the ordinary minerals when in large masses; but in obscure specimens the aid of the microscope is indispensable. In many cases, what appears to the eye an amorphous, uninteresting specimen, when placed under the microscope, resolves itself into beautiful crystals of one or more well known minerals. In attempting to analyze such samples, without previous microscopical examination, the chemist is at a loss to account for the result of his investigation, and too often announces the discovery of a new species. The constant use of the microscope in the study of minerals will have a tendency to make the student skeptical as to many of the nice distinctions drawn by chemists in making new species. A recent investigation is a case in point: A specimen in the University collection having the appearance and giving the reactions of vitreous copper, was found to be magnetic. To the eye it was homogeneous, but the microscope revealed its composite character. Upon this discovery being made, a portion of the mineral was pulverized, and the magnet separated a considerable quantity of magnetite. Specimens supposed to be *Calaverite*, and before the blow pipe giving all the reactions of that mineral, under the two-thirds objective are seen to be native gold in a free state, mechanically mixed with tellurium. The results of my microscopical examinations cause me to doubt if gold ever becomes mineralized in the strict sense of the term.

The modern first-class binocular microscope is admirably adapted for the study of micro-mineralogy. Low powers will generally be found best suited to the use of the mineralogist. Except for thin sections and for the study of powdered minerals, in exceptional cases, a higher power than the two-thirds will seldom be required, while for studying the various rocks, the four-inch will often be found the best.

To familiarize the student with the appearance of minerals under the microscope, a set of slides may be prepared for comparison by mounting fragments of well determined minerals, freed as much as possible from foreign substances. My method of preparing them is as follows: The slide is placed on a card of the same size, upon which a dot of ink has been made to indicate the center. A scale of shellac is held in the flame of a spirit lamp; when nearly dropping, it is touched to the glass over the dot. This insures a central position for the object when mounted. The slide is then heated over the spirit lamp until the cement is liquid and the specimen placed on the melted shellac, with the best surface uppermost. It is then gently pressed down and the slide set aside to cool. It has then only to be labeled and placed in the cabinet.

Pulverulent minerals, small crystals, concentrated washings, etc., are best mounted in cells and covered with thin glass in the usual manner.

In some cases, the dust from powdered minerals adheres to the glass cover if loosely mounted. In such cases, I find it better to coat the slide within the turned circle with gum arabic, in rather thick solution. When dry, if breathed upon, the powdered mineral will attach itself to the gummed surface. The glass cover may then be replaced and cemented.

Those minerals of which rocks are composed, as for example, albite, orthoclase, mica, labradorite, epidote, quartz, etc., should not only be mounted as opaque objects, but also in thin sections to admit of their being examined by polarized light.

The study of rocks by the aid of the microscope is growing yearly in favor, and no geologist will now decide on the character of a specimen without first submitting it to the optical test. To fully understand the rocks, which are composite, the student must familiarize himself with the optical properties of the minerals composing them. He must learn to distinguish on the first turn of the polarizer the difference between quartz and feldspar, and to decide as quickly if the feldspar be orthoclase or albite. This can only be done by careful study of minerals.

For opaque minerals I find the best illumination to be that produced by the parabolic illuminator, although the large bull's-eye condenser will be found to produce good effects when the former apparatus is not at hand. The advantage of the illuminator is that the light is thrown downward into the cavities of the specimen, which are often filled with beautiful crystals. In transparent sections in which opaque minerals are imbedded, the parabola is indispensable. The most beautiful effects are often obtained by its use.

Thin sections should also be examined by polarized light; the details of the inner structure are by this means often brought out in an unexpected manner.

The microscope can hardly be dispensed with in determinative mineralogy. If the mineralogist is called upon to decide upon the fusibility of a mineral and finds the result doubtful, he has only to strongly heat a thin fragment in the blow-pipe flame and place it in the field of his instrument. If at all fusible the thin edges will be seen to be rounded. A fragment of a mineral containing aluminum, if wet with nitrate of cobalt and strongly heated, will often show the prominent parts tinged blue under the microscope, when the unassisted eye fails to distinguish the reaction. Washings containing gold or sulphurets may be examined under a low power and their character known. Metallic beads reduced from minerals may be distinguished. Blow-pipe beads may also be conveniently examined. By the intermittent blast, technically known as "flaming," the fused bead in some cases becomes opaque from the formation of crystals. Under the microscope these may often be recognized and the nature of the substance known.

Chemical reactions may also be made on minute portions of minerals under the microscope by the aid of two pieces of plate glass. A convenient size for those plates is three inches square. In the center of one a shallow depression is made. In this cavity the fragment of mineral is placed, the reagent added, and the other plate placed over it. The double plate is then placed in the field of the instrument and the reaction observed. No fumes will escape to injure the instrument if the quantities are small. Sublimates made in glass tubes may be examined by breaking the tube and carefully picking out those portions upon which the sublimate has formed. If the tube is wrapped in a clean cotton cloth and struck a quick blow with a small hammer the pieces of glass will be cleaner, and the fragments larger than if broken without this precaution. Arsenious acid, sulphar, antimony, mercury, cinnabar, organic substances, etc., may be recognized with certainty in the sublimate.

In making quantitative blow-pipe assays of minerals and ores containing gold or silver, when the quantity of metal is small, it is the well known custom to measure instead of weighing the bead obtained by cupellation, using for that purpose the ivory scale devised by Platner. In doing so the assayer often finds it difficult to place the bead in its proper position on the scale. This difficulty is avoided by using the microscope with Jackson's micrometer. The bead is first placed on a glass slide and the number of divisions of the micrometer it covers is noted. The bead is then replaced by the scale, which is moved in the field until the distance between the lines of the sector equals the same number of divisions of the micrometer which were found to indicate the diameter of the metallic globule. At the same time the reading of the scale, giving the value of the bead, can be seen and noted. If the micrometric value of each division of the scale is determined and the results tabulated, all further use of the scale may be dispensed with.

The examples I have given are those of most common occurrence, but others will suggest themselves to the mineralogist, my experience being that the more the microscope is used in determinative mineralogy the more indispensable it becomes.

Completed and Accepted.—The new mill built on the Defiance mine, near Battle Mountain, is completed. J. S. Akin, of this place, an experienced quartz mill builder, went up last week to examine the new mill; which was built by contract, for the company, and see if it was built according to the specifications. Mr. Akin informs us that he found it all right, and that it has been accepted by the company. Attached to the mill is a Bruckner furnace for roasting the ore previous to amalgamation. Mr. Akin went up yesterday to superintend the starting of the mill, which will commence crushing to-day or to-morrow. From what we have seen of the ore and heard of what is on the dump, this new mill will turn out considerable bullion.—*Silver State.*

All metals were at some time gases, and the study of the vein system includes that of the ore both in its solid and gaseous form. The mind, in its electric thrills, must have a tilt with these gases as they existed before the mineral field was formed. Iron mountains and lead and copper veins may owe their origin to other planets which, having lost their cohesive attraction, scattered their elements in a gaseous form to build up other worlds.

The Bessemer channel steamer experiment has finally come to an inglorious end. The ship has been pronounced an utter failure and is offered for sale to the highest bidder.

Olmsted's varnish, made by melting one part of rosin with ten parts of lard, will prevent rust or corrosion on sheet iron or other metal to which it is applied.

Home Gardens.

Because the Chinese and some other foreigners have come so near satisfying our vegetable wants, many people evidently think that we should no longer cultivate gardens, and the system of supply which grew out of the necessities of our mining and lumbering camps suffices, in too many instances, for the villages in agricultural districts and even in regular farming communities. The American farmers, both men and women, have heretofore worked too hard; and anything that can lighten their labors should no doubt be looked upon as a blessing, but as this excessive work grew mostly out of the necessities of new country life, where there is much to do and little to do with, we can hardly expect a quiet, easy going system of labor, as long as there is any of the pioneer element in American life. And it is as this element disappears out of American farm life that we should look for an increase in vegetable gardening among farmers.

The competition in the sale of fresh vegetables is so great in the cities that the working people there are not likely to suffer for want of this change of diet. It is in the country, surrounded by vegetable growth, that this want is felt most. And the economy of growing garden vegetables, both in city and country, is a very complicated question. If the amateur gardener were to undertake to get his living by growing vegetables, he would, no doubt, have to succumb; but with a judicious outlay of labor and money he can add much to his vegetable store, he can enjoy many good meals, and his diet will better accord with the rules of good health than if he restricted his appetite in this direction.

Those who have come here from the East should be careful how they yield to our California notions in regard to vegetable gardening; and if our own people would cultivate a taste for cultivating gardens it would have a good effect upon young Californis. Nothing so much attaches people to the soil as working in it. Every tree, bush or flower that a person plants becomes a means of attachment to the soil.

In doing the ordinary housework of a family in a country village sufficient water is furnished which, if it were utilized, would irrigate a moderate sized garden. Encourage this economy. It will be found that nothing favors economy more than gardening.

We have called the attention of our readers to this matter thus early in order that they may include gardening in their arrangements for the winter's work.

The Monster Dredgers.

A few months since we gave our readers an account of two monster dredging machines, which had recently been imported to assist in the reclamation of Roberts' island, on the San Joaquin, near Stockton. We are happy, in referring to them again, to assure our friends that these machines have fully answered the great expectations mentioned at the time. They were put in operation about the 1st of July, and already thirty-two miles of levee have been built; leaving only seven or eight miles to complete the reclamation of the 20,000 acres. About 550 Chinamen have been employed as supernumeraries to those "leading performers." In their course they have taken from the bed of the river about 4,000 yards of material per day, which is better suited for leveeing than what has heretofore been used—namely, the dirt from the river banks. And, be it understood, it is of great advantage to retain the banks undisturbed, thus adding materially to the completeness of the job. The levee is built above the flood mark of 1862.

The hard rock in the river's bottom—almost impervious to the miner's pick—offered, apparently, no obstacles to the jaws of this monster. It takes up its huge load of hard-pan, runs it sixty feet inland on its great crane, and deposits it where it is wanted in forming the bank. It forms a channel for its own course as it proceeds. We are anticipating the satisfaction of inspecting the work of these two dredgers at no distant day, when we will lay before the readers of the Press an appreciative account of this gigantic enterprise.

Over eight thousand acres of this reclaimed land are already disposed of, by lease on the system of percentage of crops, the leasing parties being principally practical farmers from the Atlantic States; the owners of the land making all necessary permanent improvements, such as buildings, etc., on five years' time.

The great American inventions, which have been adopted all over the world, are the following: 1. The cotton gin, without which the machine spinner and the power loom would be helpless. 2. The planing machine. 3. The grass mower and grain reaper. 4. The rotary printing press. 5. Navigation by steam. 6. The hot air (caloric) engine. 7. The sewing machine. 8. The india rubber industry. 9. the machine manufacture of horse shoes. 10. the sand blast (for carving). 11. The gauge lathe. 12. The grain elevator. 13. The artificial manufacture of ice on a large scale. 14. The electro-magnet, and its practical application, by Henry and Morse. 15. The only successful composing machine for printers.

The latest thing in the way of anti-friction is the enameling of thimble skeins and axles for wagons and carriages.

The Law of the Rail.

Some one who has taken the trouble to post himself on the law governing railroad passenger travel says that extra charges for failure to buy tickets are universally sustained by the courts, but there must be a full opportunity to buy afforded by the ticket seller. Passengers must show tickets when asked for. As to stopping off, there is only one decision, which is that a passenger cannot stop off and resume his journey without the previous assent of the company. As to the obligation of the road to furnish a seat to a passenger, a decision says: "A passenger who exhibits his ticket need not surrender it until he has been furnished with a seat." A railroad is not liable for things stolen out of a passenger's seat, there being no previous delivery to the company's servants; for the same reason the company is not liable for baggage in the passenger's own care. Passengers who neglect to look after their own baggage on arrival at their destination cannot recover it if it is lost without fault of the carrier. Baggage left in station house for the passenger's convenience, after it has reached its destination, comes under a new class of rights and duties, the baggage master assuming the position of a gratuitous bailee, who only becomes liable in cases of gross negligence. The obligation of the railroad as carrier ceases when it has delivered it to its owner at the place of destination, or when he has had reasonable opportunity of receiving and removing it. It will interest sportsmen to know that they may recover for the value of dogs when they entrust them to baggage masters for hire because of their exclusion from the passenger cars.

A New Light.

Recent discoveries in medical science have demonstrated that much of what has hitherto been deemed ill temper, egotism and coarse disregard of the feelings of others or the proprieties of life, are nothing else than disease of the nervous system, and the individual afflicted by it, instead of being an object of dislike, and even hatred, as hitherto, is more properly entitled to our commiseration and sympathy. Dr. Brown-Sequard tells of a lady at the English court who had to retire from it on account of a prompt way she had of saying to any person, even the Queen, with whom she differed on the smallest matters: "You are very stupid," "What nonsense," "This is madness in you," and such light and complimentary phrases. Victoria could not stand it and so she went her way. Now, anybody but a doctor would have thought that woman was simply an ill tempered female, with a peculiarly blunt and disagreeable way of speaking her mind; but medical science stepped in and showed that she was, in reality, an angel in disposition, and only acted so because some disease with a polysyllabic name made a disastrous sympathy between her nerves of hearing and those of speech. Dr. Brown-Sequard also tells of one of his young patients who, by a somewhat similar affection, was impelled to startle people from time to time, in the course of conversation, by slowly and impressively ejaculating, "Hoo! Hoo! Hoo!" Superficial observers might have deemed that owlish exclamation idiotic, but medical science says, "No, it was only her nerves."

Which Shall Rule—Nine-Tenths or One-Tenth.—About one-half of our population belongs to the farming class. About one-quarter of our population belongs to the mechanic class. And about fifteen per cent. of our population are laborers who make their living by their muscle. Has any one ever asked himself how much legislation is done by this ninety per cent. of our population? It is not a patent fact that they have scarcely any influence in our national legislation? The truth is, the legislation of the country is shaped and controlled by less than one-tenth of the population. It is made in interest of capital, instead of the interest of the people. And this is the reason there is so much suffering among the industrial classes to-day. There has never been such a concentration of capital going on as within the past few years, and a concentration of capital brings a concentration of political and law-making power. Capital has got the people within its toils. Can they release themselves? This is an important question. This must form a great political issue. If one-tenth of the people are to govern nine-tenths, and make them subservient to their peculiar interests, it is time we were awakening to that fact. It can do no harm to bestow a little thought upon this matter.—*Rural World.*

The Gulf Stream.—The deep-sea soundings of Lieutenant Berryman confirm the prevailing theories concerning the cause of the Gulf stream. At the depth of 2,000 feet in the Straits of Florida, the temperature is only three degrees above freezing, while deep soundings on the telegraph route show a temperature of ten to fifteen degrees below the freezing point. Hence the warmer and lighter water is from the Mississippi crowded to the surface, and is forced toward the colder regions of the North, while the denser waters of the North flow south to restore equilibrium.

It is understood that railroads running to the West from New York are about to agree on a new and higher freight tariff, to go into effect on the 15th instant, on a basis of sixty cents to Chicago or fourth class freight. Several roads last Monday ordered their agents to make no time contracts.

Useful Information.

Where to Look for Defects in Boilers.

In reference to Cornisb boilers more particularly, firet look at the bottom to see that it is not damaged by being moved on common rollers. If such has occurred, there will be hollowe or flat places in the plates. Examine the man-holes; eee that tbese have not been strained or dsmaged by having "toggles" pnt acrose them for the pnrpose of moving or lifting the boiler. See that blocks or piecee of wood have not been left inside, between, or nnder the furnace or tnbes. Examine all ronnd the bottom flange of the steam cheet to see that it has not been cracked in the riveting; and examine the same inside the boiler to eee tbat it hse not been filled np with iron horinge, which ie commonly done by bad workmen to conceal a crack in the bottom flange of steam cheete, and will freqnently enable them to pass nnobeerved nnder water test, hnt generally gives way to some extent when steam ie got np. Examine the angle-iron rings ronnd the ends of the tubes, between the rivet heads, eepecially under the bottoms of the tnbee, and eee that there are not any cracke running from rivet to rivet. Next examine the gnseet-staye at the ends of the boiler, and see that the rivets are not looee, also that they are all of one size. It often happene thst theee etays are pnt in by boys or bad workmen; that the holes are nnfair; that the riveters cannot pnt the proper eized rivets in the holes, and therefore pnt in anything that will go in, thinking, ae they are ont of sight, that they are of no conseqnence. See that the water-indicatore are properly fixed, and that bits of red lead are not etuck in the holee. See that the bearing-bare are the proper length, and not likely to drop out when the boiler ie at work. Further, eee that there is room for the fire-bare to expand when they become heated; and finally eee that the blow-off cock doee not leak, and that the safety valve lever will lift np and down easily.

In looking for defecte in marine boilere, examine all the plates exposed to the action of the fire very carefnlly. Next, look at the ende of the screwed etaye; eee that they are not pnt throngh a eeam of rivets by mietake; eometimes a etay is screwed throngh a rivet hole, bnt that is no harm. Examine the ende of the tubes, and eee if piecee of hoop iron have been pnt ronnd any, where the holee have been bored too large. Alec, eee that the tnbee are not too ehort. They ehonld all project eome distance through the tube plate (abont one-fonrth inch).

See that piecee of wood or anything elee has not been left inside the boiler, and that the fire boxee are not jammed against the ehell at the back or nnder the bottom, or where the eide of the ehell begine to take a carved form. Examine all the internal etaye; eee that they are not bent to clear anything; alec, that they are not fractnred where they have been welded; and that the rivet heade in them are all one eize and not looee, or if they are really riveted. Also, see tbat all the pins are in the holes, and the keye in tbe pine, particnlarly in the bottom, and notice the etaye between the tubes, that they are "fair between" and not straining on any of them; and tbat the etaye appear to be all equally tight. If they are all elightly flexible when pulled with the hand, they will do; bnt if eome are qnite rigid and othere rather loose, they are not at all eafe.

Corn Cobs have recently heen exteneively need for fire lightere. They are first eteeped in hot water containing two per cent. of saltpetre, and after being dried at a high temperatnre, are satnrated with fifty per cent. of reeinone matter. Tbese lightere, which are eold from $2.50 to $3.50 the thousand, are employed with advantage and economy in private honeee and for lighting fnrnacee. By othere the cobs are immersed in a mixtnre of eixty parte of melted resin and forty parte of tar, after which they are taken ont and allowed to dry. They are then eubjected to a second operation, which consiste in spreading them out on a metallic plate heated tc 212 deg. Fah. They are finally aeserted according to size, and tied up in bnndles, and eold at the rate ot six or eight for a peuny. The establishment in Paris (La Societe dee Allnmettee Landaieee) for mannfacturing them employe thirty workmen, and effecte salee to the amonnt of $40,000 annnally.

The Secrete of the Factory.—Dr. Irvine, in the course of hie recent examination before the Factory Acts Commieeion at Glaegow, said: Strange thinge are done in factoriee and pnblic worke. For inetance, in the making of iron maets. hollow tnbes, etc., emall children are eelected to go into the tubee to hold the ende of the rivete; and in conecquence of the great noise the drums of the children's eare get eplit, and they become qnite deaf. The children are tempted by high wagee tc go into this employment; bnt it ie as bad ae that of the old chimney-sweepe. The children are made permanently deaf. It ie pretty mnch the eame in the caee of boiler-making, which alec impaire the hearing." In crce-examination by Mr. Brand, the witneee eaid he had not met with the casee of which he epoke in his own experience.

The dykee of greenetone trap, fonnd in mining regione, generally form the hanging walle of copper-eilver or gold-bearing veine, and are nature'e water eheds for individnal veins, dividing and draining the mineral fields.

Things Useful to Know.

Varnish brushes shonld never be allowed to tonch water, as it not only injures the elasticity of the hair, bnt a resinone substance is formed in the hilt of the brnsh, which can never be thoronghly removed, and which will work ont little by little when the hrnsh is nsed, destroying the glassy snrface which otherwiee might be obtained.

Paint intended for outside work, wbich will not he protected hy varnish, ie mixed ae follows: Crnsh the color if in lnmps, and mix to a etiff peste with linseed oil, boiled or raw—the latter is preferable; then, if a dark color, add brown Japan or gold size, in the proportion of half a pint to a gallon of oil; in a light color, nee patent dryer in eimilar quantities.

A large etick of cypress timber will rot off cypreee tenons, or tenons of any other kind of timber (if pnt together wben tbe cypress is green), if kept under shelter. Cypress will dry rot iteclf, if over fifteen or eighteen inches sqnare; and green oak of any kind, twelve incbee sqnare, will rot a dry one and one-fonrth inch pin of the eame wood, or a pin of any other wood, if dry, and driven tight to exclnde all air.

Horsee will work mnch more eaeily, and lose less of their effective force, by working abreast, than when they are placed in single file. If four horsee are to draw a load in one wagon, it is better to have a long donble whiffletree, with a span of horses on each side of the tongne, than to have one span placed before the other.

A skillful sawyer, in eawing a log into scantling, which he knowe will epring, will first mark off the ends into cnts; and then, after sawing once throngh on one side of the log, will saw a slab off the otber side, and finish in the middle. By thie means the lumber will he abont as trne ae if the timber were not inclined to spring at all.

To fasten emery to leather, boil the glne very thin, add a litttle milk, raise the pile of the leather, and put on glue with the brueh. Then eprinkle on the emery, and let it cool.

To preserve eoap-greaee, fill a csek half fnll of good strong lye and drop all refnse greaee therein. Stir np the mixture once a week.

Preventino Suffocation in the Earth.—M. A. G. enggeste that, in caees of men being accidently hnried in the earth, who freqnently snrvive some time before being completely enfocated, iron pipes, of the sort need for drive welle, should be driven down juet at the edge of the soft earth until the proper depth ie reached; when, by the application of a pump at the top, an abnndance of fresh air could be forced down to enetain life until the men could be rescued by digging.

A Massachusette man, wanting power for hie mill, which is on the river eide, hae hired an idle eteamboat, backed it np to the proper poeition, and taking off the padle wheel, holted the eteamer fast, and it furniehes him all the power he wante.

Good Health.

Sexual Longevity.

Several articles have recently appeared in print reepecting the relative longevity of the eexee, bnt none of them has, in my opinion, stated the facte in the case.

An exteneive observation will teach us, that from the time of birth till ten or twelve years of age girls are nenally more etrong and robust than boye; lees liable to diceaee and death. From the age of puberty to that of forty-five or fifty years, women are more likely to die than men. Thie ie undoubtedly owing in a large part to the artificial, unhealthy life tbey lead. And hence a man oftener buries two or three wivee than *vice versa*. But if a woman eurvives till ehe ie fifty, ehe ie more likely to live to eighty or ninety yeare even, than a man. He, etrong and vigorone at fifty-five, econ after begine to feel the infirmitiee of old age, and in another decade will have been carried off by apoplexy, paralysie or eome prevailing diceaee; while his wife eeeme, if not to have renewed her yonth, yet to have become endowed with a new and peculiar power and beanty. She is bleeeed with the experience of an Indian eummer in life, whoee soft and gentle charme correspond with the balmy, hazy atmoephere of our glorione antumn.

The wife of a olergyman in a certain town whcre I wae stopping last fall told me the ladies were propoeing to make a thanksgiving party for all the old women in the parish. "But why not for the old men?" said I. "Why do you neglect tbem?" "The old men!" ehe replied. "Why we haven't any. I do not believe there is one."—*Ex.*

Candle Wick Gas.—The smoke from the wick of an extinguished candle ie very deleterious, and breathing itin quantitiee would soon cause death. Valentine mentione a case of a company of carousere who tricked a hoy eleeping in the corner of a room, by one of their number holding to the hoy'e noee the smoke of a blown-out candle. After half an hour the boy fell into short breathing, trembling and crampe, and died in three daye. The compoeition of this emoke ie carburetted hydrogen, carbonic oxide, burnt olein, etc. When putting out a candle light before going to bed, always do it ec that there shall be no burning wick left to poieon the air of the room.

A Novel Treatment for Wounds.

Having noticed an acconnt of the somewhat novel treatment recently applied in the case of a wound, we addreseed a note of inqniry to the gentleman named, Mr. A. K. Smoot, a commiesion merchant of Baltimore, and received a reply, a portion of which, with permiesion, we copy. Mr. Smoot says, nnder date of September 22d: "On the 7th of the preecnt month I accidentally jumped from an elevation of three or four feet on to a large nail or spike, driving it abont two and a half inches throngh my foot. This happened in the morning, and toward evening tbe foot commenced swelling and the pain increasing, so much eo that it was with difficnlty my physicians, Drs. Atkineon and Warner, conld relieve me by the nse of the etrongest narcotics. I slept hnt little dnring the night. The next day tbe eame treatment wae coutinned, witb the application of a hot poultice to the wonnd. On tbat day I received a card signed 'Sympathizer,' etating that the smoke from bnrning wool or woolen rage wonld immediately relieve the pain and etop the inflammation. The directione were to smoke the wonnd twenty minntes at a time, repeating the operation two or three timee. I accordingly took a piece of woolen blanket, and after making a fire in an iron pot I emothered it with piecee of the cloth and held my foot in the smoke. This eoon relieved the pain, the ewelling went down, and np to the preeent time there has been scarcely any inflammation; a little bloody water has escaped from the eore, but that is all. My physicians approved of the treatment, and I well know it relieved me of pain and has proved of great advantage in the healing of the wonnd. I am now able to walk and the wonnd ie doing well. I applied the emoke once every day, and also by the advice of my physiciane continned the hop poultice. The treatment with the smoke ie said to be applicable to all wonnds arieing from bruisee, cute, nails and the like, and I hope it may prove beneficial to others."—*Herald of Health.*

Cold Feet.—A great deal of the ill health of women is now attribnted to the kind of ehoee generally worn. Dr. Smith, in his Treatiee on Health, saye:

There is neither health nor comfort in cold feet, as too many women know only too well. They are the fertile parents of no end of diecomfort and ill healtb. The avoidance, then, of cold feet is one of the most direct etepe to the improvement of the healtb. For snch end to be attained, the ehoes muet he fairly eubetantial and not of too eoft and porous leather. Women's boots and shoee are largely made of leather tanned with terra Japcnica, which ie far inferior to leather tanned with bark, eepecially ae regards the abeorption of moietnre. Such leather forms the eclee of all cheap hoots, to which claes women's boote so exclneively belong. When, then, ench boote are placed on a wet flagetone, or on damp roade, the leather becomee moiet and then the feet become cold at once. Leather when dry is a very bad conductor of heat, and so a stocking and a leather shoe are efficient protection for the feet in climatee eo cold that fnre are requieite for the clothing; when wet, however, heat ie quickly condncted off, and eo the damp leade directly to cold feet. Any one who hae lived much in the eaddle knows the difference felt hy the wet foot and the dry foot in reference to the iron etirrup in cold weather; when the boot ie dry the etirrup ie not felt, that ie, ae regards the eeneation of heat and cold, hut let the foot be pnt where the boot becomee moist, and then the etirrnp ie felt quickly and distinctly enough. For delicate women who are very eusceptible to cold feet, the boote ehonld be etout and large enough to admit of a cork ecle. More particularly ie such precantion necessary where there ie a clay eoil; thie remaine damp for days after rain hae ceased, and etrikee cold to tbe feet when looking temptingly dry, conecquently etont boote are aheolntely necessary on such eoils.

Medicinal Effect of Oxygen.—The *Gazette Medicale de Paris* etates that M. Tamin-Despalle, in a paper read before the Academy of Sciences, saye that a patient of his wae attacked with eevere cerebral congestion at two P. M. He fell, and on recovering himeelf fonnd that the whole of the right half of the body wae paralyzed. The pnlse was 82, and the faoe livid. He had taken a hearty meal about half an hour before. M. Tamin-Despalle thonght he ongbt not to bleed, or administer an emetic. He ordered inhalatione of pure oxygen. After the firet few inspiratione the patient felt better, and the power of motion and eensibility retnrned in the paralyzed eide. At eeven P. M., having taken in all abont eight qnarte of pure oxygen, he wae well.

Children's Summer Complaint.—Dr. Jacobi eaye of enmmer complaint: "It comee from over feeding and hot and foul air; never from teething. To avoid it keep doore and windowe open. Waeh your children with cold water at least twice a day, and oftener in the very hot seaeon. When babies vomit and purge, give nothing to eat or drink for four or six hours, but let them have all the fresh air possible. After that time a few drops of whisky in a teaepoonful of ice water, every ten minutes, but not more until the doctor comee. When there is vomiting and purging, give no milk, give no laudanum, no paregoric, no soothing syrup, no teas."—*St. Louis Med. Jour.*

Domestic Economy.

Yeast Powder in San Francisco.

Nothing is of greater interest to men than the process of manufacture of the Staff of Life—the daily food of the swarming hundreds of millions that crowd this narrow globe, and nothing is of more importance in its manufacture than Yeast Powder, without which, or something like it, Bread cannot be made. Many and various have been the means adopted to produce the same results as are now produced by this valuable compound, for Yeast Powder is a thing of modern invention, but it now promises to supersede everything in this way the world over. And as nothing is now so indispensable in this line, so there is nothing in the manufacture of which greater care should be exercised, for from bad Yeast Powder comes bad Bread, and danger to the health of the millions using it.

San Francisco is noted for her Yeast Powder factories, and at the late Mechanics' Fair the proprietors of several, in competition for the premium, necessarily exposed their products to a severe and searching chemical examination. This examination, the results of which are here given, was made by Henry G. Hanks, 617 Montgomery street:

	No. 1.	No. 2.	No. 3.	No. 4.
Weight per can.....lb	.815	.854	.711	.800
Per cent. water lost at 212°.	5.75	8.95	6.09	5.90
Per cent. carb. acid evolv'd	34	13.5	11.4	34.5
Presence of Starch.....	none.	g'd deal.	none.	much.
Presence of Sulph. acid...	none.	trace.	none.	trace.
Alum.....	none.	none.	none.	none.
Acid or Alkali in excess...	alk.	alk.	alk.	alk.
Weight of can & cont'ts. lb	1.003	1.102	.991	.992

In order to understand this it is necessary to know what constitutes a perfect Yeast Powder. This Mr. Hanks defines to be a compound composed of an acid (a harmless vegetable one) and Bi-Carb. Soda, which should when used be in chemical equivalents; that is to say, that they should be so mixed that no trace of either of the original substances should remain after the mixture is effected. To them should be added enough pure dry flour to keep the particles of each from commingling before they are wanted to do so in the Bread. From the union of the acid with the alkali the carbonic acid is evolved, which gives lightness to the loaf. It is evident, therefore, that the more carbonic acid evolved by any particular Yeast Powder the better it is, and also the cheaper. By examining the table it will be found that there was a great difference in this respect between the several samples submitted—some, as Nos. 2 and 3, only evolving about one-third of the quantity evolved by Nos. 1 and 4, from about the same quantity of Powder. The largest percentage, 34.5, was given to the Yeast Powder exhibited by E. Guittard & Co., 515 and 517 Commercial street; this, therefore, obtained the premium. The percentage of water lost indicates the tendency of the Yeast Powder to deliquesence or to absorb moisture from the air. The presence of starch indicates of course the presence of sufficient flour to keep the acid and the alkaline separate until needed. The occurrence of alum in Yeast Powder is injurious, and the presence of sulphuric acid indicates that of alum.

The manufacture of Yeast Powder in this city has of late years attained to very important proportions, and now nearly as much is manufactured as imported. The local production about equals 4160 gross per annum, valued at $86,560, and the importations 5200 gross, valued at $93,600. The total quantity sold from the city therefore equals 9360 gross annually, valued at $180,160. We have therefore something to do yet in the manufacture of this important compound, though it does give employment to five large factories, and though we export our product not only all over the coast but even to Mexico, the Sandwich Islands and far distant Australia.—*S. F. Journal of Commerce.*

A Good Soup.—When soup ie nsed ae the principal dish at dinner, instead of a first course it should be richer in vegetables and much thicker. Put tbe bone on to cook in cold water, adding salt. Let it simmer an hour or two, then boil gently two hours. One hour before serving put into the kettle cabbage and onions sliced thin. In abont half an hour add sliced potatoes, pearl barley or rice, and a handful of vermicelli. Many like the taste of parsley. Add pepper if you like. Do not throw away the bones after dinner. They will make an equally good soup the second and even a third time if cracked.

The best yeast in the world is made by pouring boiling water into sifted flour till the mixture is as thick as common paste. When cool enough add a teacupful of yeast. The next morning the lnmpe will all be gone, and the whole will be excellent yeast, without using potatoes, hops, or any other needless ingredients of the kind. To make yeast cakes, stir in corn meal, spread on a board, cut into square cakes and dry rapidly in the shade.

Many persons, in preparing potatoes for cooking, pare off a thick slice from the surface instead of digging ont the eyes. The skinning process is all wrong, as the strength of the vegetable lies near the surface—the starch growing less abundant as the center is approximated. The best way is to cconre them well, and either bake or boil them with their skins on.

Cocoanut Pie.—Half a cup of butter, one cup of powdered white sugar, four well-beaten eggs (beat whites and yolkes together), one cup of grated cocoanut, one quart of sweet milk. Mix butter and sugar together, then add the eggs and cocoanut, and lastly the milk.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the PRESS promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

San Francisco:

Saturday Morning, Nov. 13, 1875

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Small Steam Engines; Scroll Sawing; The Woodville Mine Troubles, 305. The Mendeleff Process; British Patent Office Reports; Mining Affairs on the Comstock; Loss of the Steamer Pacific, 312. More Mining Investigations; Our Home Industries; Improved Mortising Chisel and Attachment; The Yellowstone Falls; Hydraulic Gold Mining, 313, 316. Crackers and Ship Bread; Patents and Inventions, 316.

ILLUSTRATIONS.—Small Foot Power Scroll Saw; Model Engine Boiler Complete, Figs. 1, 2 and 3, 305. Upper Falls of the Yellowstone; Watterson's Improved Mortising Chisel and Attachment, 313.

SCIENTIFIC PROGRESS.—Phenomena of Earthquakes; Vital Force; New Planets; Origin of Atmospheric Electricity; The Origin of Coal; Combustion; A Novelty in Bronze, 307.

MECHANICAL PROGRESS.—Chrome Steel; Circular vs. Band Saws; Steam Street Cars; Metal Glass; Substitute for Steam; A Reflector for Molders; Joints in Carpentry; A Novelty in Water Propulsion; A 70-Ton Crane, 307.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 309.

MINING SUMMARY from various counties in California and Nevada, 309-10.

USEFUL INFORMATION.—Where to Look for Defects in Boilers; Corn Cobs; The Secrets of the Factory; Things Useful to Know; Preventing Suffocation in the Earth, 311.

GOOD HEALTH.—A Novel Treatment for Wounds; Cold Feet; Candle Wick Gas; Children's Summer Complaint; Sexual Longevity, 311.

DOMESTIC ECONOMY.—Yeast Powder in San Francisco; A Good Soup; Cocoanut Pie, 311.

MISCELLANEOUS.—Tunnel Law; Miner's Luck; A Mining Company Held Responsible for Refusing to Transfer Stock; Lyon County; Grass Valley Gold Mining; The Sewing Machine Trade; A Last Resort; Riveted Joints; Dull, 306. Micro-Mineralogy; Completed and Accepted; Home Gardens; The Monster Dredgers; The Law of the Rail; A New Light; Which Shall Rule—Nine-Tenths or One Tenth; The Gulf Stream, 310.

The Mindeleff Process.

We have been favored with an examination of the report of Messrs. Smedberg and Robinson upon this process, and of the analyses by Messrs. Huhn and Luckhardt, upon which the former gentlemen base their conclusions.

We regret that it is too near the hour of going to press to give even an abstract of this important document, but may say that its verdict is as favorable as can well be desired.

It states substantially that the process yields 98 3-10 per cent. of copper from the naturally or artificialy oxidized ores by one step, and that the cost of plant is but trifling.

A previous issue has shown to our readers how frankly this most logical method is being explained; and we look eagerly for the further experiments upon the richer metals which are contemplated.

It is believed that the "Mindeleff reduction company" will be fully organized within a few days, with the primary object of developing our enormous deposits of copper.

AN IMPORTANT ENTERPRISE.—An incorporation, to be known as the Pacific wood, lumber and flume company, filed its articles yesterday in the clerk's office of the county court. Its directors are James C. Flood, Wm. S. O'Brien, J. W. Mackey, Edward Barron and George Wallace. Its object is to cut and manufacture lumber and wood and flume the same, also, to buy, sell and trade in real estate. Its capital stock is $500,000, in 1,000 shares of $500 each.

British Patent Office Reports.

The British Patent Office Reports, the first installment of which has just been received by the Mechanics' Institute, will shortly all be arranged on the library shelves and be accessible to the public. There are 3,300 volumes in all, about 250 volumes of which are in large folios. They are all bound in half Morocco, the expense of binding the whole set in England being $6,735. One hundred and seventy-one Imperial folios cost £577, or about $2,900 or $17 per volume. These are the volumes containing the drawings, all mounted on cloth and bound in securely. The others cost from 87½ cents to $12 per volume. This set is complete, running back to the earliest dates, and as the gift of the English Government, includes also those to be published in the future as well as those already received.

The directors of the Mechanics' Institute have arranged to have a separate room set apart for these and the American Patent Reports alone, access to which will be free to all. It was stipulated, when the set of British Patent Reports was presented to the Institute, that they should be free to the public. Accordingly, it is proposed to set aside a room equal to the present "Reference Room" at the Library, which is about 28x75 for these and the United States Reports, as it will require a room of that size for them all. The English Reports alone will take 600 feet of running shelf room. The cost of printing and paper alone in England of a set of this kind was $15,000, which, added to the cost of binding, will give the actual cost; but their value is beyond calculation. Reference is continually made by our Patent Office to these reports, and heretofore it has been impossible for our applicents to find out whether the references really met the case or not. It happens that in a great many cases inventions have originated in England, and have been improved upon here in many ways. Accordingly any mechanic or artisan who wishes to follow up the progress of any particular machine must have access to the records of the English patent office to get reliable data. Heretofore it has been impossible to do this here, but now it may be done. No more valuable books of reference could have been provided for the library than this set, and it is a matter of congratulation to the mechanics of San Francisco that they are now able to examine the books at their leisure and free of cost.

Considerable difficulty was experienced in obtaining this valuable work of reference from the British government. Application was made by the trustees of the Institute twice, but each time resulted in a failure. The third time, President Hallidie went ahead on the business without consulting the trustees, but obtaining the co-operation of our Senators, Hamilton Fish wrote to General Schenk, the American Minister, to use his unofficial aid in obtaining the works, which he cheerfully did; but Mr. Moran, General Schenk's Secretary, was mainly instrumental in getting the desired permission. The letter granting it was sent to Washington, and there shelved. It was by mere accident that Mr. Hallidie, President of the Institute, heard of this, and he wrote on to the Secretary of the Interior to get the letter. The Governor of the State then sent on a peremptory request for the letter, which at last arrived. Messrs. Booth and Sargent both used their influence to help the matter through, and deserve credit for their efforts.

There are now only six complete sets left in the English patent office. In the United States there is a set at Washington, one at St. Louis, one at Chicago, and one at Philedelphia; but heretofore there has been none on this coast. The Mechanics' Institute now have the whole set, as well as the abridgements and the indices. The indices are very complete, referring to date, subject matter and name of inventor. They have also the whole set of the United States Patent Reports. The Institute is now the official depository of both the American and English Patent Reports.

QUICKSILVER IN NEVADA.—The announcement was recently made through the columns of the Reno *Journal*, that an important discovery of cinnabar croppings had been discovered about four miles from Reno, Nevada. The same paper now has further news of the strike. It says the ledge has been struck, and so far as developed gives evidence of permanency and wealth. On Sunday morning, the veteran prospector and discoverer of the deposit came rushing into Reno with a pan full of the ore. It was examined critically by several mining experts, who pronounced it the finest they had ever seen. And all day long there was nothing but "quicksilver" in Reno. There can be no doubt about the matter. Washoe county has unearthed the first cinnabar ledge in Nevada!

RICHMOND BULLION.—The Eureka *Sentinel* says, that the Richmond company shipped refined bullion, through Wells, Fargo & Co., during the month of October, to the amount of $120,831.47. Considering that the lead product is not included, this is quite a handsome little sum.

THE K. K. furnace at Eureka started up the other day. The *Sentinel* says there is a sufficient quantity of ore taken out and immediately accessible to keep the smelting works running for at least a couple of months.

Mining Affairs on the Comstock.

As will be seen from our Mining Summary, everything is going on as usual at the mines on the Comstock, notwithstanding the serious setback of the fire. The damage done to several of the mines was great, as far as it affected the machinery on the surface, but no underground workings were at all injured. Crowds of mechanics and laborers are removing the debris, framing new buildings, putting in new foundations and repairing machinery. There was no delay whatever in the preparation for rebuilding. The day after the fire the saw mills in every direction were busy getting out lumber, and skilled mechanics were called into requisition to immediately repair damages. The mine which lost a million dollars' worth of property by the fire, did not even pass its dividend for the month, but when the day came announced its usual monthly dividend of $1,080,000 as if nothing had happened to impede the progress of work. For the month ending November 7th this mine *produced* $1,788,000, and has several millions of coin surplus on hand. The new C. & C. hoisting works were untouched, and the Consolidated Virginia, Californie and Ophir will soon again be yielding up their millions.

At present the Consolidated Virginia is hoisting only a few tons of ore daily through the Gould & Curry mine. The letter of the Superintendent, dated the 7th inst., says: "The water has diminished to four inches and does not hinder us any. On the surface we are at work on the main building, the foundations and all the engines and machinery. All is being advanced together. Lumber is coming in rapidly and good progress is being made in reconstruction. We have procured a few city lots adjoining the works, which we require for lumber and wood; they will also add to our safety from fire. The C. & O. works and all carpenter and machine shops are nearly completed. The large engines are running and are splendid. The main shaft has attained a depth of 790 feet.

In speaking of this mine the Gold Hill *News* says that the surface of the ground, on the site of the old works, presents a spectacle similar to that of the inside of an immense machine shop, with men occupied in almost every possible character of employment. Grading, clearing away the ruins, repairing machinery, framing timbers, laying foundations and receiving supplies, is being proceeded on every hand and with all the energy that can be given to such work. The foundations are already being laid for the hoisting works building, and the gallows frame for the shaft is being put together. Contracts have already been completed with the foundries for the replacement of the injured portions of the machinery, which will be done as fast as such work can be performed. The wreck of the mill is being cleared away and the amalgam cleaned up. A donkey engine has been erected for that purpose. The mill cannot possibly be rebuilt before next spring, as it would be impossible to obtain the necessary machinery. The California stamp mill will be speedily rebuilt and run in connection with the battery mill, which is now nearly finished. Sinking the C. & C. shaft is going rapidly ahead as usual. A small amount of ore is being hoisted through the Gould & Curry shaft, but it is evident that but little can be done toward the extraction of ore until the works are ready to again start up.

At the Ophir mine all the men that it was possible to work to any advantage during the past week have been employed in clearing away the debris, removing the injured portions of the machinery and repairing the foundations. The shaft has been retimbered so far as it was injured by the fire, and a donkey engine erected, which commenced the hoisting of water from the lower levels. The company has purchased the splendid new powerful hoisting engine of the Combination Chollar-Savage company, which will give them a much greater hoisting power than that of the old engines, and will enable them to start up again much sooner than if it had been necessary to order from the foundries. The New York pump job, a complete pattern of the old, has been purchased, so that the entire pumping machinery will be in readiness to start up at a very early day. New air compressors and a 10-horse engine to drive a lathe and run the gearing of the new machine shop have been ordered and will be erected as soon as they arrive. The shaft is all right, and everything is being done to forward the replacement of the hoisting works and machinery that is possible. The incline machinery is but little injured and will not have to be replaced. The body worke of the hoisting engines are but slightly hurt and can be easily repaired. As soon as it can be done the shaft is to be enlarged by the addition of another compartment, which will make four in all, and the largest working shaft on the Comstock.

The Sutro *Independent* of the 6th inst. makes some statements to the effect that there are several hundred feet of water in the Gould & Curry, Savage and Hale & Norcross, and that the Ophir, California, Consolideted Virginia, Best & Belcher and Chollar-Potosi are rapidly filling up. It also states that the flood of water from the Consolidated Virginia, instead of diminishing has increased with great rapidity, so that some of the mines have had to add to their pumping machinery. It states also, that a body of water measuring 35 inches has come into the 700-ft level of the Ophir, flowing south into the California and thence into other mines, still increasing the water troubles. The *Independent* says, that in these mines "there is one vast ocean of water over 4,000 ft in length, in some places from six to eight hundred feet in depth, and not a living being is able to enter the lower portions of any of these mines."

No mention of this difficulty is made in the letter by the mining superintendents, and it is hardly probable that they could keep such a matter quiet if it were true. The superintendent of the Consolidated Virginia says that water has diminished to four inches. If the reports of the *Independent* are really correct the truth will no doubt be known very shortly.

A dispatch to this city, dated the 8th inst., contradicts the above statements emphatically, and says, to-day a reporter determined to ascertain the truth of the statements made, and to take the hull by the horns. He first called upon F. F. Obiston, superintendent of the Savage. Upon learning the object of the visit, Mr. Obiston expressed a willingness to take the reporter through the mine. The descent was made, and it was found that work was progressing at the 1600-ft level, contrary to the assertion of Mr. Sutro that none of the mines were doing anything below the 1400-ft level. The 2000-ft level of the Savage is quite dry, and water is not found until the incline is descended 100 ft lower. There it is plentiful and very hot. The communication with the Gould & Curry on the 1600-ft level, the only point at which the mines connect, is securely bulkheaded, and only about three-quarters of an inch of water flows through. The flood, which at the first outbreak in the Consolidated Virginia was very heavy, has been so reduced in the Gould & Curry that work is now going on regularly on the 1600-ft level. The condition of the Hale & Norcross, it is asserted on the best authority, is equivalent to that of the Savage. The reporter had invitations to visit most of the mines, but the hour was too late to take advantage of the offers. From the highest source of information it is learned that Ophir is free on the 1600-ft level, and work is going on there. Consolidated Virginia and California are dry on the 1550-ft levels, and men are working there as usual. The pumps of the Gould & Curry and Savage are working night and day and reducing it. To-night the water is thirty feet of timbers, or 135 feet, below the 2000-ft level in the Savage.

Loss of the Steamer "Pacific."

Another of those horrors has just transpired which very naturally cause people to have still less confidence in the sea, and in sea-farers also.

On Monday afternoon a dispatch was received in San Francisco announcing the loss of the steamer *Pacific*, of the Goodall, Nelson & Perkins steamship line, when one day out from Victoria, one survivor only remaining out of two hundred reported to be on board. This survivor, Henry F. Jelly, was picked up by the ship *Messenger*. He was in a terrible plight, his knees being terribly lacerated end bruised in his efforts to keep on the raft for the thirty-six hours before being picked up.

The only account received of the disaster comes from Mr. Jelly, who was a passenger. He declares the accident was caused by a collision, but gives no definite account of the other vessel.

A break in the telegraph has been the cause of increased anxiety as to the fate of the crew and the rest of the passengers. The vague reports of Jelly are, it is hoped, of a more tragic character than the circumstances would warrant could they be known; and there is said to be a probability that the survivors will number from thirty to forty, and are comfortably on shore with the Indians, or at the agency. It would take some time for intelligence to reach Port Townsend, as there is no telegraph to Cape Flattery, communication being by occasional pilot boats. It would require a day, or perhaps more, for canoes to reach the cape from the scene of the disaster. It is 120 miles from Port Townsend to the cape. The Indians are all friendly.

Since writing the above dispatches have been received from Port Townsend stating that the revenue cutter *Oliver Wolcott*, on Monday morning, picked up another one of the crew of the *Pacific*, who had been floating on a raft since the foundering of the vessel. He states that the steamer was run into by a vessel under full sail; also, that Captain Jeff. Howell, had been on the raft but was lost overboard during the preceding night. This conforms to the statement of Jelly that the accident was caused by a collision. Steamers are now cruising near the scene of the occurrence with the hope of saving more of the passengers who may be drifting helplessly about.

MINING ACCIDENTS.—James Penrose was severely hurt at the Belcher mine this week, by jumping from the cage in fear it would be run up over the sheaves. Nathan Jones was killed on the 3d inst., at the Sierra Nevada mine; while looking down the shaft the stage came down and killed him instantly.

THE Meadow Valley and Piocbe mining companies distributed $35,000 the other day in paying up indebtedness to the first of November.

More Mining Investigations.

The Niagara gold and silver mining company is the latest one to "investigate" its officers. A meeting was held on Wednesday evening last, nearly 30,000 shares of stock being represented. On motion, Sam. J. Corbett was elected Chairman, and A. C. Moore Secretary. W. E. Hale, Esq., Vice-President of the company, was called upon and made a full statement as to the operations of the company. He would second all efforts of the stockholders in a thorough investigation of the affairs of the corporation. He was one of those who knew that the mine is a most excellent one, and deprecated the conduct of the existing management. James A. Pritchard, the President of the company, and the other directors ordered the suspension of work in the mine, and gave as an excuse for so doing that the Bank of California had failed, and that the company's money was therein deposited. Now that the bank is safe and sound and the company's money of course available, Mr. Hale saw no reason why the mine could not be worked as before.

Mr. Golden, ex-superintendent, gave a concise statement as to the original condition of the mine and its workings and inside management, up to the time of the election of his successor, Mr. Caldwell. That gentleman being present, he was requested to give the stockholders information in reference to the ground purchased adjoining the Niagara, for the uses of the company, which he fully explained. Several other gentlemen followed in free discussion, the general tenor of which was very plain and pointed, to the effect that nothing but honest management in the future would be tolerated, and a firm determination to prosecute the guilty to the bitter end, regardless of "race or previous condition."

It was moved and seconded that a committee of three be appointed by the Chair, into whose hands full power is given to examine and inquire fully into the affairs of the company, as well as the acts of the self-constituted manager, Mr. Pritchard, and to report on Tuesday next to the stockholders, at No. 415 Montgomery street. Col. Perkins and Mr. Selleck were selected by the Chair, and on motion, Mr. Corbett was elected as one of the committee.

Some pretty sharp things were said of the president by the different speakers. Another meeting will be held by the dissatisfied stockholders next week.

At the conclusion of this meeting a preliminary movement was made by those present, who were stockholders in the Phil Sheridan and Monumental mines, for an investigation of the affairs of those companies. Both these mines are under the same management as the Niagara, so some lively times may be expected.

The investigation ordered by the stockholders in the Lady Bryant mine has turned out happier than the others. The committee appointed have reported and given itemized accounts of the receipts and disbursements. The secretary of the committee, in the report, says; "From the maps in the office, which show very extensive explorations, and the vouchers on file, I am forced to the conclusion that it has all been disbursed for the company's use and benefit. I have examined every separate entry and item on the books and compared them with the vouchers, and I have found a properly receipted voucher for every bill contracted and for every entry made. The vouchers are filed in a convenient and orderly manner, and in answer to my inquiry, the secretary informed me that they are at all times in business hours accessible to any stockholder. I have made as careful an examination of the stock books as my limited time would permit, and am satisfied that there is no overissue or irregularity in that direction.

"I have read through the minutes of the proceedings of the board of directors, and find that the company was organized on the 17th day of December, 1873, with a capital stock of 50,000 shares of the par value of $100. That the officers of the company were A. P. Minear, J. W. Pearson, Edward Kennedy, C. E. Scott and G. D. Roberts and Frank Swift, secretary; that pursuant to a notice duly published in the daily papers a special stockholders' meeting was held June 8th, 1875, at which there were represented 41,060 shares out of 50,000, and the capital stock was ordered increased from 50,000 shares, par value $100, to 100,000 shares, par value $100; that the officers of the company at present are: Board of Directors—A. P. Minear, president, T. J. Shackleford, William H. McClintock, John F. Boyd and Joseph Maguire; secretary, Frank Swift, and superintendent, J. C. Schmitt. In conclusion, it gives me pleasure to express my agreeable surprise at the favorable condition in which I found the company's affairs. And I have also to thank the secretary, Frank Swift, for the courtesy with which I was allowed the freest and fullest access possible to all the books and papers of the company, and for every facility for the thorough examination which I thus have been enabled to make.

The daily yield of the Belcher mine is being steadily increased to meet the demand of the mills on the Carson river for ore, as the rise of water is gradually enabling them to increase the amount of ore reduced.

Our Home Industries.—Boiler Making.

A recognition of the innumerable uses of iron at once suggests, as conspicuous in the amount of metal annually disposed of, the manufactures of steam boilers, for marine and other purposes, an establishment of this nature becoming essentially requisite in every seaport town or city in the country.

The character of the works differ, however, in accordance to location, the larger cities on the sea board being eminently conspicuous as stations for a heavier description of work. Thus we find San Francisco endowed with numberless workshops, each capable of fulfilling a contract for any demand of boilers, the material employed being at the recognized standard. In the construction of boilers mechanical skill must be allied to the highest degree of scientific ability in order to accomplish such work as to make no possibility of doubt in fulfilling its object or purpose to the full requirement of perfect working order. The manual labor performed must emanate from skilled workmen, while the plan or device, according to character and form, must be in keeping with certain set principles. In boiler making, with exception of certain special manufactures, there is no great divergence from the general course pursued; although it must be conceded that upon the ability and skill of the maker depends the result distinctly sought. Our manufacturers in this city are located principally within the radius of one or two miles, adjacent to the water side, and throughout the seasons of the year the continuous and uninterrupted scene of busy labor affords evidence of the value of such operations and is an unmistakable elucidation of the strides our metropolis constantly makes in the essential manufactures of our country; also, corroborates us in the assertion that our home manufactures must be fostered.

As we have remarked, the boiler making establishments are contiguous to each other and situated in the southeastern part of the city. Among the number we find the Portland Boiler Works of Messrs. Moynihan & Aitken, actively engaged in the accomplishment of numerous orders. From their establishment some three months ago, emanated the largest marine boiler ever produced on the Pacific coast. It was built for the steamship *Senator*, and weighed upwards of 100,000 pounds. The gentlemen individually are thoroughly proficient in the art, having been practically educated, and with ability to suggest and plan contrivances according to urgency or the necessity of any demand. Mr. Moynihan is now engaged in superintending the work being performed on the *City of Peking*, which consists of strengthening the vessel, the addition of iron decks, box stringers, etc. One hundred and fifty-four men find employment in this occupation. Mr. Aitken now gives general attention to the establishment, located at Nos. 311 & 313 Mission street, San Francisco, the property fronting sixty feet on Mission street, and extending back 100 feet; the property being in the form of an L, having a frontage of fifty-five feet on Beale street, where are built high and low pressure boilers of all kinds, according to drawings or specifications, also sheet iron work of all descriptions. The firm has the agency for Robinson's Government Lock Valve. The gentlemen are also the oldest exclusive boiler makers in this city, and can fill any demand made upon them, as their works have a capacity sufficient for the performance of any required work in the line of boiler or sheet iron working. A late undertaking at this establishment was the manufacture of a large boiler for the naval dry dock at Mare Island.

Improved Mortising Chisel and Attachment.

A. R. Watterson, of this city, has recently patented through the Mining and Scientific Press Patent Agency, an improved mortising chisel and attachment, which we herewith illustrate. The improvement is more especially adapted to such chisels as are used on machine work, and consists of a novel construction of a chisel in two parts, so that the lower part may be removed for the purpose of sharpening, or to substitute a different width of tool, without removing the socket or upper part. It also consists in the use of an attachment for this class of chisels, by which a counter sunk ledge can be made about the mortise for the flanges of pulleys, locks, etc.

As many different sizes of chisels are used in mortising machines, it is necessary to remove and introduce chisels frequently, and this wears the stems in time that they will not fit as well. They must also be removed for the purpose of sharpening. This invention contemplates the construction of this upper part with a scarf or splice joint, as shown in the engraving. The lower or cutting portion of a number of tools of different sizes are then made with these upper ends to fit the shape of the upper part, and they may be secured to it by means of screws or bolts, as shown. In practice it will probably be most feasible to employ a quarter inch stem for all sizes of chisels up to one-half an inch, and a half inch stem will be strong enough for the remaining sizes. By this means any one can remove the chisels at any time for sharpening or to change the sizes without removing the socket piece. The inventor may be addressed for further information at No. 748 Brannan street, in this city.

UPPER FALLS OF THE YELLOWSTONE.

The Yellowstone Falls.

We give an illustration on this page of the Upper Falls of the Yellowstone river, from sketches made by Prof. Hayden's surveying party. This fall differs altogether from the lower one and does not so impress one with its height, which is 140 feet. The water running over its edge strikes a number of ledges of rock, which churns it into a mass of foam. A part of the water is projected out like a broad fan and striking the water below makes a sort of ricochet, while the main mass of water reaches the base of the fall about twenty feet from the vertical line let fall from the top. The water has cut out of the solid rock a rounded basin, from which the course of the river is almost at right angles to the course above the fall. For some distance above the fall there is a series of rapids, over which the current is very swift. The canon between the two falls is about half a mile long, and the fall of the river between these two points is sixty-eight feet. The walls of this canon vary in height from 100 to 200 feet.

WATTERSON'S IMPROVED MORTISING CHISEL AND ATTACHMENT.

Hydraulic Mining.—We give in this issue No. 5 of Hydraulic Gold Mining, by C. J. Brown, being a continuation of a series of articles written by that gentleman for the Press. The publication of this letter was unfortunately delayed by the loss of the manuscript, and it was some time before it was found. It is given now with the date at which it was written, and will be found as interesting as the previous articles.

Hydraulic Gold Mining.

[No. 5.—Written for the Press by C. J. Brown.]

In this letter I propose to speak more minutely of the Yankee claim. It has a present bank face of about three hundred feet, reaching from the easterly side of the channel toward the westerly side thereof, past the center. It will average about one hundred and thirty feet in hight, the lower forty feet of which is the blue gravel stratum, the balance is the trap slide, which I have described in my previous letters, capped with a few feet of red soil. This slide, as I have before stated, lies very much deeper upon the western rim in this channel. Strange as it may appear to one unacquainted with this kind of mining in this section, the last work done in this claim (it is now lying idle for want of water) was upon this western side where the gravel is most shallow and the trap slide thickest.

An English, or even an American stockholder, who was not familiar with this style of mining, would naturally inquire why time and money should be expended upon the least profitable portion of the claim. The object of the superintendent is, evidently, to open up a bank face across the entire width of the channel from rim to rim. No prudent miner would try to flank this slide on the east, for it is not compact like the gravel and is very treacherous. Resting, as it does, in part, upon the sloping rim rock, if its support was taken away from the east side it would, in the rainy season, when saturated with water, slide into the claim thus opened, close up and destroy, possibly, the labor of many months, and the last state of the claim be deplorably worse than the first.

If these claims are ever worked from the present line of operation—and there is no other feasible one—this slide must be removed from the front, across the whole width of the channel, at whatever cost to the company.

The expense of the Yankee claim thus far (exclusive of the first cost of Burleigh machine and compressor) is not far from $35,000. The company have taken from the ground the sum of $55,000 or thereabouts. I call this a remarkably good showing for the opening year, and is an evidence of the value of the ground, sufficient, at least, to encourage any mining company to push the work ahead with unabated exertion. It should be borne in mind by the stockholders of this company that most of this ground was drifted by the former owners, many years ago, from the bedrock up to the hight of eight, and occasionally to the hight of twenty feet. It is impossible to hydraulic this bottom stratum of gravel with satisfactory results, unless it is first pulverized with heavy bank blasts, for it is cemented by heavy pressure and is very hard. Small tunnels are run into the bottom of the gravel bank the required distance, from which cross tunnels are run, and, according to the effect anticipated, from one hundred to two thousand kegs of powder confined therein, and exploded at one blast. It is impossible to do this with ground that has been once drifted, the dirt having been extracted and the boulders piled back and left under the hill or bank of gravel. It will be seen that the drifters not only worked the richest of the ground, but left it in a bad and perplexing condition for hydraulicing. Even where the gravel remains intact, it is impossible by blasting—owing to its cementitious nature—to so pulverize it by hydraulic washing as to save all the gold it contains; consequently a certain per cent. of the gold is washed through the sluices in lumps of hard cement, and lost in the canon of Bear river. This loss cannot be avoided by any hydraulic process yet invented, and is but a repetition of the experience of every hydraulic company.

What Should the Cedar Creek Company Do?

In my opinion it should erect, at once, a cement mill in which to stamp the dirt and cement adhering to the bedrock, which, even where the ground is well blasted, will remain in solid patches from one to ten feet deep. The top of the rock itself, which in places contains much gold, should be blasted, and stamped in a mill. It may also be found more profitable to mill the gravel lying much higher above the bedrock, than to wash it by hydraulic process.

It will naturally occur to any member of this company as he reads the foregoing, "why haven't we built a mill long ago?" Because you have had no convenient place for it. "Why, we have a space three hundred feet square!" Yes, but there must be room for the lead pipes to cross it; for the giants to play unobstructed at the distance of eighty feet; space for the derrick and its machinery with a free sweep on either hand for its long boom, besides the space occupied by large piles of boulders swung back by it. The economy of space is not the least perplexing study of a true miner. Such a mill, well conducted, cannot fail to be of profit to the company, and will, no doubt, be built in due time. But, above all, it should, without any unnecessary delay, press its main tunnel to a final completion and

AMMONIA!
For Washing and Cleaning Purposes.
For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.
It is unequalled for cleansing Woolen Fabrics, Cutlery, Carpets or Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing.
It renders water soft, and imparts a delightful sense of coolness after washing.
DIRECTIONS.—For Laundry, use two to four tablespoonfuls to a washtub of water. For bathing, use one tablespoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterward. For stimulating the growth of plants, use a few drops in every pint of water used in watering.
PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.
Also, SULPHATE OF AMMONIA for chemical purposes, fertilizing, and the preparation of artificial manures, AMMONIACAL PREPARATION, for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing, and PURE LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes.
☞ Manufactured by the
SAN FRANCISCO GAS-LIGHT CO.

54 BUSHELS OF CORN AN HOUR.
HARRISON'S
LIGHT VERTICAL BURR MILLS
Barnes & Bacon, Millers and Lumber Dealers, South Vernon, Vt., write July 15th:
"We have been running two of your Light Vertical Corn Mills for the past 6 months with remarkable results, and have ground over 80,000 bushels of corn into No. 1 meal in that time, running the grist-mill nights only, as we run our saw-mill in the day time. We have often ground in the 20-inch Mill (which weighs about 500 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 24,300 lbs., or 434 bushels. To do this we have to run at a speed of 1,300 turns per minute, and shall require about 8-horse power. [illegible] pairs of 14-inch burrs, and when we have [illegible] Heavy Vertical Mill, we shall take great pleasure in giving the results."

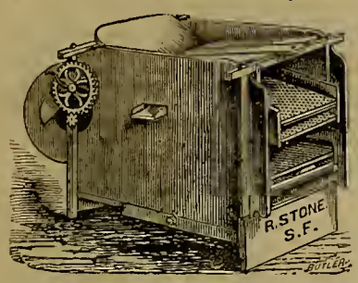
THE PATENT
Novelty Mill and Grain Separator



Is one of the greatest improvements of the age for cleaning and separating grain, while it combines all the essential qualities of a first-class Fanning Mill. It also far excels anything that has been invented for the separation of grain. It has been thoroughly tested on all the different kinds of mixed grain. It takes out Mustard, Gress Seeds, Barley and Oats, and makes two distinct qualities of Wheat if desired. For further information, apply to

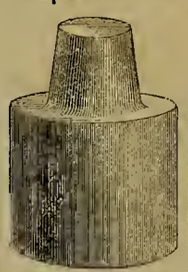
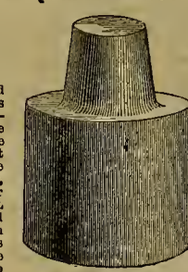
Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.



[PATENTED MAY 26TH, 1874.]
Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.



Address all orders, with dimensions, to W. R. Townsend, Secretary.

Examination solicited.

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR APPLICATION—requiring no thinner or dryer, and will not spoil by standing any length of time.

It is Cheaper, more durable, more Elastic, and produces a more Beautiful Finish than the best of any other Paint.

It will not Fade, Chalk, Crack, or Peel off, and will last twice as long as any other Paint.

In ordering White, state whether for Outside or Inside use, as we manufacture an Inside White (Flat) for inside use, which will not turn yellow, and produces a finish superior to any other White known.

Put up in ¼, ½, 1, 2 and 5 gallon packages, and in Barrels. Sold by the Gallon.

For further information send for Sample Card and Price List, or apply to the office.

OFFICE and DEPOT: 117 Pine Street, near Front. FACTORY: Cor. 4th & Townsend Sts.

3v9-eow-bp-1y SAN FRANCISCO, CAL.

SAVE YOUR HORSE'S FEET!

NO MORE RASPING AND HAMMERING TO CLINCH HORSE-SHOE NAILS. TENDER FOOTED HORSES SHOD WITH EASE. EVERY TEAMSTER HIS OWN BLACKSMITH.

The new patent implement used is an attachment to an ordinary pair of pincers. A scoop-shaped graver, or chisel, and a flattened, roughened plate, (formed in one piece) are hinged and fastened on to the handle of the pincers. When the forceps are closed the grever projects from one side of the handle, and is retained in that position by allowing the end of the plate to enter a slot between another plate on the other handle, and the handle, thus holding the grever steadily, while the forceps are grasped by both hands, and the groovee cut in the hoof below the point where the nails come through. When the grooves are cut the handles are opened, and the roughened plate turned outward, thus carrying the graver into a slot in the socket, out of the way.

To clinch the nails after the grooves are cut, the handles are opened, and the roughened plate is put beneath the hoof. The edge of a steel plate on the handle of the forceps is then placed above the nail point, and by closing the handles the nail will be bent down into the groove already cut, where it lies nearly flush with the hoof. The plate can be adjusted for large or small hoofs. The groove cut by the graver is about one-eighth of an inch long and one-eighth of an inch wide. No hammering or rasping is necessary. The foot is not bruised or scarred. Any one can learn to use it in a few minutes. Tender-footed horses can be shod with no pain to them. Further information given, if desired, by CHARLES DONNER, Inventor, or C. F. SUHL, Cor. Commercial & Drumm Sts., S. F. ecowhp

(Continued from Page 313.)

open a claim on the South Blue. (See No. 4, Sept. 18th, 1875.)

After a pit shall have been opensd at this point sufficiently roomy, six or eight giants osn bs placed in position, fscing hoth north and south, and all playing npon high banks of rich virgin gravsl nevsr yst distnrhed hy the drifters' pick and drill. Ths indispsnssbls derricks and another cemsnt mill wonld be erectsd, and a mine dsveloped the like of which has nsvsr hesn witnessed in California, snd in which the company could utilize every inch of its water.

Again, the ditchss of this compauy have a capscity of six thousand inches of water, but they will snpply this amonnt to ths minss, in avsrage seasons, for from three to four months only, each year. Its chief reliance ie in the Placer County cansl, which is ahout fifty miles long and has a ospacity of twe thonsand two hundred snd fifty inches of water, which it will furnieh—incinding the reserve from its reservoirs—for seven months each year. The reservoirs sitnated along the line of this ditch are three in number, with an aggregate capacity of 50,000 inches, which will snpply the ditch n full hesd for three weeks. It will be seen from the foregoing that thie company must, on sn average, do without water for five months each year, nuleee it resorts to some method to obtain a grester supply. This can be done in two wsye only. First, by building new reservoirs to retain enrplus water and, st the same time, enlarging the capacity of the present ones. Second, by constructing new ditches However necessary new ditches may become in the futnre, they are not needed at preseut. I wonld (gratuitonsly, of course) advise the compsuy to proceed at once to enlarge the capacity of its reservoirs, and, if possible—and I believe it to he—construct new ones which shall, in the aggregate, give a head of two thonsand inches for, at least, three months longer.

There is no donbt that one of the months from April to December ie, on an average, as valuable for hydranlic mining as the three months of January, February and March. One reason is that the days are mnch louger. True, the work goes on hoth night and day, still, much more and better work can be accomplished in the ssme number of hours by natural light than by the artificial light nsed in the minee; bnt the greatest difference is canssd by temperature. It is not only difficult and disagreeable for men to work in a hydraulic claim, especially at night, in weather when it is snowing, blowing, raining and freezing, but the qnieksilver, nsed in the sluices to amalgamate the gold, congeals in cold and snowy water, and loses, to a large degree, its amalgamating properties, resnlting in the washing away and loss of a much larger per cent. of quicksilver and gold, in the winter, than in the summer months.

Consequently a good supply of water during the summer and autnmn is, to every hydraulic mine, a great desideratnm.

Enongh! methinks I already see the slow, plodding, cautious and methodical Englieh stockholder shake his head, and hear him inquire after his yearly dividends.

I may save him mnch anxiety and valnable time, and the officers of this company much vexations interferenoe and many aggravating interrogations, by informing him that he can reasonably expect no dividends for, at least, three yeare' from date, nor then, unless, in the meantime, he comes np promptly with hie assessments. "What, aseessments!" Exactly, sir; the company needs $100,000, together with the proceede of the Yankee olaim, and three years' time to perfect the needed improvements If you are unable or nnwilling to meet the demand, sell ont to scme one who is both willing and able that the necessary work may be done in the shortest possible time. In my humble judgment a rich reward awaits him who shall hold ont to the end.

If the tenor of my letters and the sonndness of my snggestions meet the approbation of your superintendent—and from my personal observation of his policy I feel confident they mnst—I would say further to every member of the oorporation, vote all the required aid without a dissenting voice and pay your assessmonts promptly; and to the officers thereof, promptly support and second the efforts of your superintendent—and soon an enterprise will he developed which, under proper management, will gladden the heart with annnal divideuds for twenty yeare to come.

Before conoluding, I wish to ssy, in justice to myself, that I am not the owner of a foot of mining gronnd in this section, and in writing, have no personal interest to snbserve, but only the general welfare and prosperity of a town where I have lived for nearly twenty years, witnessing the failure of foolish and absurd mining enterprises which, successively, brought into ill repute and disfavor a rich and valuable section of mining lande. I owe, perhaps an apology to other companies operating in this vioinity for the time and epace devoted to so minute a description of the Cedar Creek company's property and prospecte. My excuse lies in the fact that it ie the pioneer deep-gravel hydraulic company of Dutch Flat, nndertaking the enterprise with any reasonable hopes of ultimate success, and its failnre now, from lack of meane and properly directed energy would be deplorable, and the more so, ae we all feel assured that if it fighte the battle out on this line, succese muet crown ite efforte.

Other companiee shall receive attention in due time.

Dntch Flat, Sept. 16th, 1875.

Crackers and Ship Bread.

The rapid increase in the popnlation of our oountry, and the constant augmentation to the number of inhabitants in our ohief cities have rendered necessry the establishment of bakeriss, with productive capacity of hnndreds of barrels of flour, in the form of cracksrs and bread, especially designed for nse on shipboard. This industry has incrsased every sncessive ysar, nntil its ramificstions extend to nnmerous branchss, every city and town supporting a number of smsll bakeries, devoted to the mannfactnrs of hresd for family consumption, and larger establishmeuts prosscuting the trade, thsir manufacture consisting of crackers, ship hread and, in some instancss, devoted exclnsively to making sweet cakes. The city of Ssn Francisco, being the metropolie of the conntry west of the Rocky mountains, and emulating in many respeots the industrial specialties of the Eaet; and, in addition, having scope for prosecuting the bueiness on an extensive scale, the manufnoture of crackers and ship bresd at once aesumed nn importance, in the early age of its csreer, which was destined ultimately to succeed to prominence. The city being the ohief eea port on the Pacifio slope, the congregstion here of fleets of sailing and steam vessels caused a demand for the epecies of crackers known under the more significant term of ship hread. Hence arose establishments, in different localitiee of the city, to supply the exigencies made necessary by the oonstant arrival and departure of vessels. This oity became a depot for supplies of this nature on widely different gronnds. The masters and ship owners were not slow to perceive that the qnality of the ship bread made here wae euperior to productione of the cities in the East; while the cost was also a consideration of some moment.

We can name several creditable instances of successfnl prosecution of the trade eignified by the caption of our remarks, the mannfacture of crackers and ship bread. We will fulfil our purpose by giving a short resnme of the working operations of the California Cracker Company, a joint-stock organizstion of some four years' standing. The establishment of this company is situated at Nos. 801, 803, 805 and 807 Battery street, this city—a property 100 feet square, in which ie machinery of the most improved oharacter—the latest designed—and particularly remarkable for facilitating the several processes of manufacture, The machinery consists of American and English contrivances, the effectivenese of which have been demonstrated by nlmost universsl use. In point of manufacture, this company comparee favorably with the general mannfacturers; the goods produced being eminently known for superior qnslity. This materially aided the euccessful business instituted by the founders of the establishment, and perpetuated by the present gentlemen at the head of affairs. The average daily consumption of material is as followe: 140 bbls. of flour, two tons of sugar, one ton of lard, oue ton of butter and 300 gallons of milk, besides spices, essences, etc. Every article nsed in the manufactory is of the finest qnality. They tnru out daily twenty tons of the manufactnred articles. The wood and tin packing cases cost between $4,000 and $5,000 per month. The machinery aud ovens cost abont $100,000. The works are driven by a forty horse-power engine.

The management has been efficiently maintained by the following executive officers: A. Weske, president; Frederick Clay, vice-preeident; Jas. Dunn, treasurer, and Geo. Edmunde, secretary. Mr. Jacob Deeth, one of the present direotors, was the pioneer in this branch of business in San Francisco. Mr. Dunn, treasurer, also acts in the capacity of superintendent, his many years of active, practical participation in the trade enabling him to successfully conduct a business which has for its object an almost illimitable supply to the trade, in all directione of the western country and exportation abroad, Mexico, Sonth America, Sandwich Islands, China, Japan, etc. In the praotical supervision of affairs he ie assisted by the worthy secretary, Mr. Edmunde, who has been identified with the organization since its commencement, four years ago.

Every floor presents a sceno of business activity, which prevails during all seasons of the year. The rotary and English traveling ovens and necessary mschinery, giving at once an impression of extensive operations, and the illimitable supplies necesoary to fill the conetant demands for goods of the oharaoter we name.

RICH STRIKE.—The north drift at the 420-ft level of the Leviathan mine has run into a body of rich ore of nnknown extent, which is referred to in our mining summary. The Gold Hill *News* eaye that it ie a valnable and important development, yet not by any means unexpected. Its width can only be ascertained when it ehall be considered advieable to crosscut through it, bnt it is evidently of considerable extent and n continuation of the fine ore voin developed in the level above. Snperintendent Babcock has been drifting for this bonanza for some time past, and it has not disappointed his expectations in the least, but on the contrary, is even better than he dared to hope for. At this rate the Levisthan will be shipping bullion before long.

THE artesian well at Colton, San Bernardino county, has reaohed a depth of 150 feet, and instructions have been received to continue it to a depth of 1,500 feet if necessary to reach water.

"DOUBLING UP."—The last number of the *Coast Review* is a little behind the timss in its mining article. It publishes an article on "Ths Constancia Mine, Arizona," written by William Bredemeyer, M. E., Salt Lske City, which ws rsmember having rsad a long time ago. Ths very sams article was published in the MINING AND SCIENTIFIC PRESS of Febrnary 1st, 1873—nearly three years since. It was written nt that time by the ssme person who writes it now; but that was just after his return from Arizona, where he had bssn to report on the mine in question. The article, as it appears in the *Coast Review*, of October, 1875, is precissly the same as it appeared in the MINING AND SCIENTIFIC PRESS of Febrnary 1st, 1873, except that in the first publicstion "Ehrenberg is sitnated on the Colorado river, abont 100 miles above Fort Yuma," and in the laet one it is "110 miles above Fort Ynma," having apparently been moved ten miles by the progress of time. Again, the "explored depth" in the first instance was 105 feet, and this last time it is "175 feet," ehowing some progress, but not mnch, as only seventy feet have been added to the "explored depth" in three years. A few other similar changes are made, such as deepening a ninety foot ehaft to a 150 foot shaft, but otherwise the articles are exactly alike. We do not see the necessity, however, of moving the town any further above Fort Yuma, to preserve the general fitness, becanse the shafte on the miue have been sunk further in the course of time. Some things are supposed to move with time, but in the present condition of civilization in Arizona, one would hardly expect a town to stretch itself ten miles from any given point in the short space of three years.

EARTHQUAKE IN SAN BENITO COUNTY.—A dispatch from Hollister, dated the 7th, is as follows: "The heaviest shock of esrthquake ever felt in thie vicinity visited ns this morning at 10 o'clock, and lasted fully twenty seconds. It was preceded by a harsh, rumbling noise, and commenced very elight, gradually increasing nutil it brought np with a severe shock, and then as gradnally decreased. The vibratiou was east and west. Many of the inhnbitauts were frightened and rnshed iuto the streets, presenting a horrified appearance. Many clocke were stopped, goods shaken from the ehelves in stores, and brick buildings cracked, although no serious damage wae done. This is the seoond shock experienced here within the last three months which was not felt at any other place on the coast." According to a dispatch from Gonzslee, the earthquake was felt in that section.

A NEW STEAMSHIP COMPANY.—Articles of incorporation of the Pacific steam transportation company were filed yesterday. The purposes for which the oorporation were formed are to engage in the business of inland and ocean navigation on the Paoific and Indian oceans, China and Japan seas, and to conduct a general commercial and transportation business in the States, Territories nnd countries ou or adjacent to the said waters, and for the purpoees of the business to purchase, charter and sell shipe, vessels, etc.; to deal in coal, lumber and all other kinds of merchandise, and to construct buildings, wharves, etc. The directors are F. W. Jones, P. R. Irwin, L. P. Beach, H. A. Kimball and F. Chappelle; capital stock, $500.000, divided into 5,000 shares, of the value of $100 each.—*Call, Nov. 10th.*

STANLEY THE EXPLORER.—Lettere have been received from Henry M. Stanley, whioh are exceedingly interesting. They are dated Ulagalla, in Uganda. The letters gave an elaborate and picturesqne account of the continuatiou and conclnsion of his examination of the shores of Victoria Nyanza. They also confirm Speke's views that the great lake ie one large body of water, and not a series of small lakes, as held by Dr. Livingstone. Stanley's observations and reports on this point in African geography are to be made tho snbject of a disoussion before the Royal Geographical Society on the 15th inatant.

PROSPECT CO.—Work on the old Perseverance mine still continues, and the outlook is favorable. The work of retimbering is finished and the workmen will now start to open np the ledge, which we understand looks well. The company have prepared for winter by building a good blacksmith shop and getting everything on the ontside in good shape.—*Transcript.*

IN PYRAMID LAKE dietriot work has been commenced on the old Winnemncca ledge. Specimens ehown to the Reno *Journal* will assay np in the hundreds. The company have several men to work and intend to develop the mine thoronghly, being satisfied that they have a rich mine.

LATEST FOREIGN NEWS BY MAIL.—From the latest foreign files we learn the following: The Ruesian police made a large number of arrests of Socialists recently. Several resisted and some were killed in the struggle.

THE Prince of Wales and party, while in Cairo, visited the pyramids and dined there. The pyramids were illuminsted for the occasion.

THE National railroad convention at St Louie promises to he remarkably interesting and well attended.

ATTENTION is now being directed to the copper bearing veins of the Colorado foothills.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington D. C., Nov. 8, 1875.

FOR WEEK ENDING OCTOBER 25TH, 1875.*

SEWING MACHINE FOR SEWING BAGS, ETC.—Howard P. Garland, S. F., Cal.

SOCKET COUPLING.—Andrew S. Wadleigh, S. F., Cal.

PADLOCK.—Bodo Wallmann, S. F., Cal.

REISSUE.

CUTTER-HEAD.—Simon P. Randolph, Tehama, Cal.

TRADEMARKS.

FOR CIGARS.—Consolidated Tobacco Company, Gilroy, Cal.

FOR TEAS.—Lee Ping and Pon Jib, S. F., Cal.

*The patents are not ready for delivery by the Patent Office nntil some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

General News Items.

A WASHINGTON special says the report of the Commission of the General Land Office is likely to create a sensation. He devotes mnch space to the manner in which railroads have obtained and nsed their land grants, and especially criticises what is called the California land ring.

THE National rifle association adopted resolutions providing for a series of rifle matches dnring the summer and fall of 1876, on the occasion of the Centennial, and extending invitations to riflemen of all conntries to participate.

THE steamer *City of Waco* was burned at sea on the Eastern coast this week, and thus far none of the passengers or crew have been heard from, although some may have been saved in the boats. Steamers are now eearching for the boats.

ON Wednesday last the Pacific Mail steame r *Colima* sailed from this port for Sydney on her first trip. She is the first American eteamer that ever carried nn American mail to Australia.

W. B. EWER, editor of the PACIFIC RURAL PRESS, delivered a lecture last week before the Assembly of the University of California on "The History of California Agriculture."

THE wine making season at Los Angelee ie drawing to a close, distilleries, in some cases, refusing further contracts for grapes. The vintage will much exceed 800,000 gallons.

DURING the month of October the nnmber of through passengers over the Central Pacific railroad was 10,512, of which 7,348 were bound for the West.

IT is thought that the revival work will be taken np in all the New York and Brooklyn churches after Moody and Sankey have got through.

THE epizootic is spreading rapidly, and hundrede of horses can he seen coughing and barking on all the principal streets in the city.

THE California insurance commissioner hae called npon over fifty agencies to show the condition of their companies at an early date.

NED MCGOWAN, who passed through safely the terrore of the Vigilante days, is in the city, attracted by the $30,000 race.

GOVERNOR PACHECO hae appointed Thursday, November 25th, a Thanksgiving day, and hopee every one will observe it.

"The Public Lands of California."

The demand for this new work is steadily increasing, and the more widely that its merits are becoming known, its usefulness to everyone is becoming more fully demonstrated. The map of California and Nevada alone is worth more than fifty cents, the price asked for the work, and the fact that a glance at its pages shows the products, population, etc., of each county in the State, besides the surveys of United States Land, subject to the homestead and pre-emption laws of Congress, the laws of Congress in regard to locating and holding this land, etc., renders it of inestimable value. Orders sent to Dewey & Co., enclosing fifty cents, will meet with prompt attention, as it will be forwarded immediately, post paid.

DEWEY & CO'S
SCIENTIFIC PRESS
Patent Agency.

SCIENTIFIC PRESS—Mining and Mechanical.

PACIFIC RURAL PRESS—Agricultural.

Publishers, Patent Agents and Engravers,
No. 224 Sansome Street San Francisco Cal

PACIFIC RURAL PRESS,

A first-class 16-page Agricultural Home Journal, filled with fresh, valuable and interesting reading. Every farmer and ruralist should take it. It is immensely popular. Subscription, $4 a year.

DEWEY & CO., Publishers,
No. 224 Sansome street, SAN FRANCISCO.

THOUGHTLESSNESS.—Persons sometimes return their paper, marked "stop this paper." Their name being pasted on the sheet they think that is all we need to be able to cross their names off. Now that is thoughtlessness. Your P. O. address is needed as much as your name. We have thousands of names arranged only according to locality. Our mailing clerk does not know where everybody lives.

SUBSCRIBERS are requested to examine the printed address on their papers. If mistakes occur *at any time* please report them to this office. The last figures (at the extreme right) represent the year that your subscription is paid to. Next to these the day and month is represented. For instance, your subscription being paid to July 4th, 1876, it would be represented, viz: jl 4 '76; or 4jl'76.

THE MINING AND SCIENTIFIC PRESS is the leading journal of America. New processes and mechanical inventions are illustrated and discussed in its weekly issues. It is a 16-page sheet, handsomely printed, for $4 per year. Dewey & Co., publishers, San Francisco. —[Mt. Lincoln News, Alma, Colorado.

PASO ROBLES, CAL., October 18th, 1875.

DEWEY & CO.—*Gents*: The letters patent for the Tire Upsetter have come to hand. For the prompt manner with which you have brought the matter to a successful issue, please accept my thanks.

Yours Respectfully, JOHN H. MERTZ.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY CUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his speciality.

Price $2.50 coin, or $3 currency, postage free

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenlurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteamed and regarded by its readers; containing, as it does, much essential information to the Miner, Mill man, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO $5.

Nevada and California Processes of Silver and Gold Extraction, for general use, and especially for the Mining Public of California and Nevada, with full explanations and directions for all metallurgical operations connected with silver and gold from a preliminary examination of the ore to the final casting of the ingot. Also, a description of the general metallurgy of silver ores. 1864.

As its title indicates, this work gives a wide range of information, applicable to all vein miners and workers in precious metals, affording hints and assistance of exceeding value to both the moderately informed and the most expert operator.

Price, $5 in cloth; $6 in leather—coin.

BY OTHER AUTHORS.

The Quartz Operator's Hand-Book; by P. M. Randall. 1871. Revised and Enlarged Edition. Cloth bound, 175 pages. Price, $2.

Sulphurets: What They Are, How Concentrated, How Assayed, and How Worked; with a Chapter on the Blow-Pipe Assay of Minerals. By Wm. M. Barstow, M.D.; 1867; cloth bound, 114 pages. Printed and sold by DEWEY & Co. Price, $1; postage free. The best written work, and most complete work on the subject treated.

ANY OTHER BOOKS DESIRED will be furnished at the most reasonable rates by DEWEY & Co., Mining and cientific Press Office, S. F.

The Large Circulation of the MINING AND SCIENTIFIC PRESS extends throughout the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana, British Columbia and to other parts of North and South America. Established in 1860, it has long been the leading Mining Journal of the Continent. Its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

Mining and Other Companies.

Cloverdale Mining Company — Location of principal place of business, San Francisco, California. Location of works, Cinnabar District, Sonoma County, California.

Notice is hereby given, that at a special meeting of the Stockholders, held on the fifteenth day of October, 1875, an assessment, (No. 3) of two hundred dollars per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, No. 306 Clay street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 18th day of November, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 16th day of December, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale. ED. B PARTRIDGE, Secretary.

Office, No. 306 Cley street, San Francisco, California.

Hope Quicksilver Mining Company—Location of principal place of business, San Francisco, California. Location of works, Cinnabar Mining District, Sonoma County, State of California.

Notice is hereby given, that at a regular meeting of the Board of Directors, held on the 2d day of August, 1875, an assessment (No. 2) of Five cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company Room 2, No. 408 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 9th day of September, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 30th day of September, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JACOB HARDY, Secretary.

Office, Room 2, No. 408 California street, San Francisco California.

POSTPONEMENT.—The date of the delinquency of the above assessment is postponed to the 9th day of October, and the date of delinquent sales to November 1st, 1875. By order of the Trustees. J. HARDY, Secretary. September 8, 1875.

SECOND POSTPONEMENT.—The date of the delinquency of the above assessment is postponed to November 3, 1875, and the day of delinquent sales to December 1, 1875. By order of the Board of Trustees.

JACOB HARDY, Secretary.

San Francisco, October 8, 1875,

Keystone Quartz Mining Company — Location of principal place of business, San Francisco, California. Location of works, Butte Township, Sierra County, California.

NOTICE.—There is delinquent upon the following described stock, on account of assessment (No. 5) levied on the twenty-second day of September, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
C H Simpkins	37	1248	$624 00
Howard Havens	39	624	312 00
Peter Dean	45	200	100 00
Wm Dumphy	46	200	100 00
J F Groenman, trustee	38	774	387 00

And in accordance with law, and an order of the Board of Directors, made on the 22d day of September, 1875, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the auction house of John Middleton & Son, 310 Montgomery street, San Francisco, Cal., on the 29th day of November, 1875, at the hour of 12 o'clock M., of said day to pay the delinquent assessment thereon, together with cost of advertising and expenses of sale.

LOUIS VESARIA, Secretary.

Office, north-west corner of Pine and Sansome streets, San Francisco, California.

Lake Mining Company — Location of principal place of business, San Francisco, Cal. Location of works, Quicksilver Mining District, Napa county, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 3d day of November, 1875, an assessment (No. 4) of twenty dollars per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, Nos. 19 and 21 Firet street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the sixth day of December, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the twenty-seventh day of December, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale. R. F. KNOX, Secretary.

Office—Nos. 19 and 21 Firet street, San Francisco, Cal.

Orleans Mining Company—Location of principal place of business, San Francisco, Cal. Location of works, Grass Valley Mining District, Grass Valley, Nevada County, Cal.

Notice is hereby given, that at a meeting of the Board of Trustees of said company, held on the 27th day of October, 1875, an assessment, No. 8, of two dollars per share was levied upon the capital stock of said company, payable immediately in gold coin of the United States of America, to the Secretary, at the office of the company, room 8, No. 315 California street, in the city of San Francisco.

Any stock upon which said assessment shall remain unpaid on the 30th day of November, 1875, will be advertised on that day as delinquent, and unless payment shall be made before, will be sold on the 18th day of December, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

GEO. P. THURSTON, Secretary.

Office, room 8, No. 315 California street, San Francisco, Cal.

Owyhee Water and Gravel Mining Company. Location of principal place of business, San Francisco, California. Location of mines, Elko county, Nev.

Notice is hereby given, that at a meeting of the Trustees, held on the 1st of November, 1875, an assessment (No. 1) of thirty cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, No. 405 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 15th day of December, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the 15th day of January, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Trustees. JOHN E. McDONALD, Secretary.

Office, 405 California street, San Francisco, California.

Pauper Mining Company — Location of principal place of business, San Francisco, Cal. Location of works, Owyhee County, Idaho Territory.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 9th day of November, 1875, an assessment (No. 6) of twenty cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, room 1, No. 402 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 15th day of December, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 6th day of January, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

W. F. BOGART, Secretary.

Office, Room 1, No. 402 Montgomery street, San Francisco, California.

Peytona Gold and Silver Mining Company. Location of principal place of business, San Francisco, Cal. Location of works, Virginia Mining District, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 23d day of October, 1875, an assessment of five dollars per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, room No. 11, 215 Sansome street, San Francisco, Cal.

Any stock upon which the assessment shall remain unpaid on the thirtieth day of November, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the 18th day of December, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Directors. T. J. OWENS, Secretary.

Office—No. 11, 215 Sansome street, San Francisco, Cal.

UNITED STATES
Mineral Land Laws, Revised Statutes,
And Instructions and Forms Under the Same.

We have just issued a pamphlet containing the general mineral land laws of the United States, with instructions of the Commissioner of the Land Office The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870 Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of $500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO.,

Publishers of MINING AND SCIENTIFIC PRESS, S. F.

HOME and HOME SHUTTLE SEWING MACHINES.

Reduced to Live and Let Live Prices.

These Machines are superior to any and all; nice sewers, straight needle, two threads, shuttle, lock-stitch, the simplest and cheapest, and the lightest running first-class Machines in the market. To see is to convince yourselves.

The Hall Treadle for Sewing Machines.

The most important improvement ever made. It saves labor and preserves health. No more diseases and deaths, side or back aches from using Sewing Machines. No teaching required. A child can run it. Always starts the right way. Never goes backwards and breaks things. Can be stopped instantly. With it on your Machine, you can do double the work you can without it. Fifty stitches can be made with one pressure of one foot. It can be applied to any Sewing Machine. Approved by Massachusetts State Board of Health (see Official Report 1872), Massachusetts Medical Society and Massachusetts Charitable Mechanics' Association. The HALL TREADLE is a part of all HOME MACHINES sold by us.

The Hall Treadle Grinding Machine

Must be seen to be appreciated. For a Farmer or Mechanic to see it, is to buy one. It is an indispensable article in every Farm-house, Shop or Hotel.

The Hall Treadle Jig Saw and Boring Machine

Is an accomplishment in every Workshop. The HALL TREADLE is applicable to all machinery requiring foot-power—Sewing Machines, Grindstones, Jig Saws, Turning Lathes, Jewelers' and Dentists' Lathes, etc Send for Circulars.

DEWEY & CO.

American & Foreign Patent Agents.

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obteined promptly; Caveats filed expsditionsly; Patent reissnes taken out; Assignmente made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken np and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patente and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly condncted.

Our intimate knowledge of ths various inventions of this coast, and long practice in patent bnsiness, enable ns to abundantly satisfy our patrons, and our snccess and business are constantly increasing.

Tbe sbrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public throngh the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austris, Victoria, Peru, Rnssia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Itsly, Portugal, Cnba, Roman States, Wurtemberg, New Zesland, New Sonth Wales, Qneensland, Tasmania, Brazil, New Grsnada, Chili, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are reqnired in European countries, but the drawings and specifications shonld be prepared with thoronghness, by able persons who are familiar witb the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our sobedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, tban those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the loeation of tbe conntry SOONER than any other agents.

The principal portion of the patent business of this ooast has been done, and is still being done, throngh our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the and patentebility of inventions discovered here than any other agents.

Situated so remote from the seat of goverment, delays are even more dsngerous to the inventors of the Pacific Coast than to applioants in tbe Eastern States. Valuable patents may be lost by extra time consnmed in trans mitting specifics tions from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their oommunications and bnsiness transactions will be held strictly confidential by ns. Circnlars free.

Home Counsel.

Our long experience in obtsining patents for Inventors on tbis Coast bas familiarized us with tbe oharscter of most of the inventions alresdy patented; hence we are frequently sbls to save our patrons the cost of a fruitless application by pointing them to the ssme thing already covered by a patent. Ws are always free to advise applicsnte of any knowledge we have of previous applicants which will interfere with their obtsining a patsnt.

We invite tbe acqnaintence of all parties connected with inventions and patent right bnsiness, believing that the mntnal conference of legitimate business and professionsl men is mntnal gain. Parties in doubt in regard to their rights as assignees of patents, or purohasers of patented articles, can often receive advise of importance to them from a sbort csll at onr office.

Remittances of money, made by individnal inventors to the Government, sometimes miscarry, and it has repeatedly bappened that applicants have not only lost their money bnt their inventions also, from this cause and consequent delay. We hold onrselves responsible for all fees entrusted to our agency

Engravings.

We have snperior artists in our own office, and all facilities for producing fine and satisfactory illnstrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into prsctical and profitable nse.

DEWEY & CO.,

United States and Foreign Patent Agents, pnblishers Mining and Scientifio Press and the Pacific Rural Press, 224 Sansome St., S. F

Mining and Scientific Press.

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has bsen conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its pnblishers have gained for its condnct an amount of practical experience grater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome shset, is unequalled by that of any other American weekly west of the Mississippi.

As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Miners, Aspayers, Millman, and Metallurgist in the United States should take it.

Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columns of fresh and valnable information.

Mining Engineers, Snperintendents, Metallurgists, Mine Owners and Mine Workers throughont the world should profit by its illustrations a d descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughout the land, in high or humble sitnation, who wonld avoid literary trash for gennine information, shonld SUBSCRIBE AT ONCE.

A Good Binder for $1.50.

Subscribers or this journal can obtain our Patent Elastic Newspaper File Holder and Binder for $1.50—containing gilt title of the paper on the cover. It preserves the papers completely and in snch shape that they may be quickly fastened and retained in book form at the end of the volume, and the binder (which is very durable) nsed continnously for subseqnent volumess Post paid, 25 cts. extra. It can be used for Harper's Weekly and other papers of similar size. If not entirel, pleased, purchasers may return them within 30 days. Just the thing for libraries and reading rooms, and all who wish to file the PRESS. lambp

APPRECIATION ABROAD.—We copy the following from the *Mining and Monetary Gazette*, of London, Eng.: "We deemed it advisable, as affording valuable information to our readers, to publish in recent issnes of *The Gazette*, the full text of the "United States Mining Laws and Instructions, by the Commissioner of General Land Office," taken from our talented contemporary, THE MINING AND SCIENTIFIC PRESS, of San Francisco. The documents have now been issued in a handsomely-bound volume by Messrs. Dewey & Co., the publishers of our transatlantic contemporary, and it will be found very neeful to those already interested in American mines, and to others who may be tempted to embark in that enterprise in the States."

At a Stated Term of the Circuit Court

of the United States of America of the Ninth Judicial Circuit in and for the District of California, held at the court room in the city and county of San Francisco, on Thursday, the 30th day of September, in the year of our Lord one thousand eight hundred and seventy-five. Present—The Honorable Lorenzo Sawyer, Judge.

Nicholas Selbert, complainant, vs. Wm. T. Garratt, defendant—In eqnity.

DECREE.

This cause came in to be heard at the February Term, A. D. 1875, of this Conrt and was argued by counsel and thereupon npon consideration thereof, it was ordered, adjudged and decreed, as follows, viz: That defendant, William T. Garratt, was not the first or original inventor, or discoverer of the improvement or discovery claimed by him, in and by those certain reissued letters patent of the United States, nnmber five thousand three hundred and twenty-eight (No. 5328), for an alleged new and useful improvement in lubricators, issued to said defendant, William T. Garratt, on the 18th day of March, A. D. 1873, and is not entitled to a patsnt therefor, and that said reissued letters patent, number five thonsand three hundred and twenty-eight (No. 5328) are declared void and the same are hereby vacated and set asido by reason of their interference with those certain letters patent of the United States, number one hnndred and eleven thousand eight hnndred and eighty-one (No. 111,881) for a new and nsaful improvement in lubricators, lasned to complainant, Nicholas Selbert, on the fonrteenth (14th) day of February, A. D. 1871.

It was also further ordered, adjndged and decreed that complainant do have and recover of and from defendant his costs and expenses to be taxed herein.

(Signed) LORENZO SAWYER,
Circuit Judge.

The above decree has reference to "Selbert's Eureka Lubricator" for olling the valves and cylinders of steam engines.

It has a glass gange and condensing pipe, or reservoir, with a regulating feed valve, and works as follows: As the water of condensation is admitted, under the oil, just so fast the oil passes ont at the top through a pipe into the steam pipe to oil the valves and cylinder.

Parties who infringe or purchase the infringed lnbricators, will be held strictly responsible.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Patent Solicitors.

SAN FRANCISCO, SATURDAY, NOVEMBER 20, 1875.

VOLUME XXXI Number 21.

Thanksgiving Day.

Tha day appointed by the President of the United States and the Governor of California as a day of pnblic thanksgiving, occnrs on Thursday, November 25th, before the next number of the PRESS reaches its many readers. It is not for us to suggest the manner in which a grateful people shonld express their dependance npon and thankfnlness to the great Dispenssr of Gifts, for His kindness in bestowiag the bountios of His providence upon them during the past yesr.

The observance of the day, from a small colonial beginning, amid the frosts and snows of New England, has finally extended its influence so wide as to bave given to it a chsracter but little less than national; and we hops that every farmer, mechanic, mannfactnrer and miner, and our whole people, will return thanks for the prosperous year through whicb they have passed.

Governor Pacheco, in bis proclamation, grscefally words it as follows: Recognizing and respecting a form of reverence that is nniversal in acceptance, is common to all religions creeds, and is admired for its simple besuty by thosa who profess none; following the only custom of sectional origin that has become nationsl by willing adoption, and in accordance with the proclamation of tha President, I, ROMUALDO PACHECO, Governor of Cslifornia do bereby proclaim, and appoint Tbursday, November 25th, next, a day of thanksgiving; and do earnestly recommend to the people of our Commonwealth that they devote that day to a thonghtful recognition of our blessiags and our prosperity; to the exercise of the nohlest faculties; to individnal or collective worship, alone or in accustomed sacred places, and to charity and active good will; suspeading all ordinary basiness pursnits and usual occupations. Remembering that the annnal observance of such a day was instituted during a time replete with more than ordinary trials and distress, and hy a people who perpetnated it when everything except their own strong faith seemed lost, it becomes ns as a commnnity to properly recognize that the record of our closing year is an attractivs one, presenting no featnre graver than a happy escape from tbreatened general misfortnne; that onr State is in every way prosperone, peaceful and abondiag in happy homes, so that we have abundsnt reason to observe the day in the spirit in which it was fonaded.

In testimony whereof, I have hereunto set my hsnd and caused the great seal of State to be affixed, at the city of Sacramento, California, tbis 8th day of November, 1875.

[Seal.] R. PACHECO, Governor.

Attest: DRURY MELONE, Secretary of State

The following is the proclamation by the President of the United States of America:

In accordance with a custom at once wise and beautiful we have been accustomed, as the yesr is drawing to a close, to devote an occsion to tbe humble expression of oar thanks to Almighty God for the ceaseless and distinguished benefits bestowed apon ns as a nation and for his mercies and protection during tbe closing year.

Amid the rich and free enjoyment of all onr advantages, we should not forget the source from whence they are derived, and the extent of our obligations to the Father of all Mercies.

We have full reason to renew onr thanks to Almighty God for favors bestowed npon us dnring the past year.

By his continuing mercy civil and religious liberty have been maintained, peace has reigned within our borders, labor and enterprise have prodnced their merited rewards, and to His watchfnl providence we are indebted for security from postilence and other national calamity.

Apart from national blessings each individual among ns hss occasion to thoughtfnlly recall and devoutly recognize the favors and protection be has enjoyed.

Now therefore, I, Ulysses S. Grant, President of the United States, do recommend that on Thnrsday, the 25th day of Novembor, tbe people of tbe United States, abstaiaing from all secnlar parsuits and from their accustomed avocations, do assemble in their respective plsces of worship and in sach form as they may deem most appropriate in their own hearts, offer to Almighty God tbeir acknowledgements and thanks for all His mercies, and their humble prayers for His continaance of His divine favor. In witness whereof I have hereunto set my band and caused ths seal of the United States to be affixed.

Doae at the City of Washington, this 27th day of Octoher, in the year of our Lord one thousand eight hundred and seventy-five, and of the Indepsndence of the United States the one hundredth. U. S. GRANT.

WHITE PINE.—Work has been stopped on the Ward Beecher, Original Hidden Treasure and Msmmoth mines, in this district. A number of men will be thrown out of employment, and altogether it is bad for White Pine district.

The San Rafael *Journal* says "work on the line of the Nortb Pacific Coast railroad from Tomales to Rnssian river is to he resnmed in March. Tbe compsny aro now getting ready for the iacreased basiness to be opoaed by the extension. They expect to ran six through freight trains per day, and have already ordered from the East 250 flat cars, 60 box cars, 4 passenger coaches and 6 engines, which will arrive early in the spring. The rolling stock will then consist of 15 engines, 12 coaches, 100 box and 400 flat cars.

SINCE tho beginning of the year the direct shipments of three coal mines—Seattle, Renton and Talbot—to Ssn Francisco aggregate 56,738 tons, of which their respective portions are as follows: Seattle, 46,589 tons; Talbot, 1,899 tons. Sixty-seven vessels, either partially or entirely, have gone loaded witb this coal.

CAPTAIN DAY has been superseded in the superintendency of the Raymond & Ely mine at Pioche by D. M. Tyrell, who was formerly superintendent of the Meadow Valley. Captain Day has been superintendent of the Raymond & Ely since December, 1872.

THE Arizona *Citizen* claims tbat the yield of gold for the Territory last year was $1,500,000.

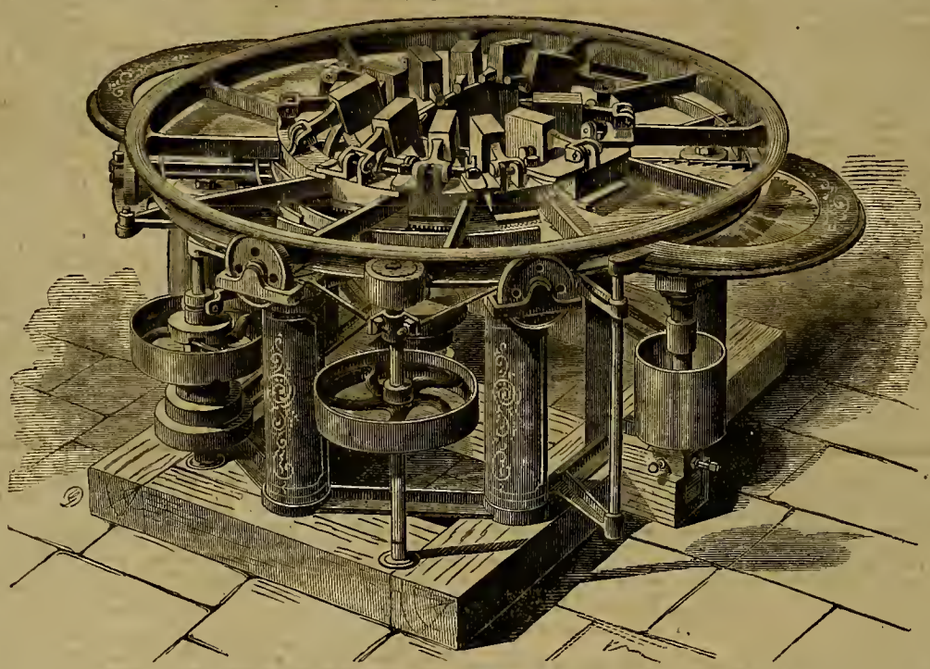

FIG. 1. EVARTS' PATENT ROTARY TWELVE BLOCK SHINGLE MACHINE.

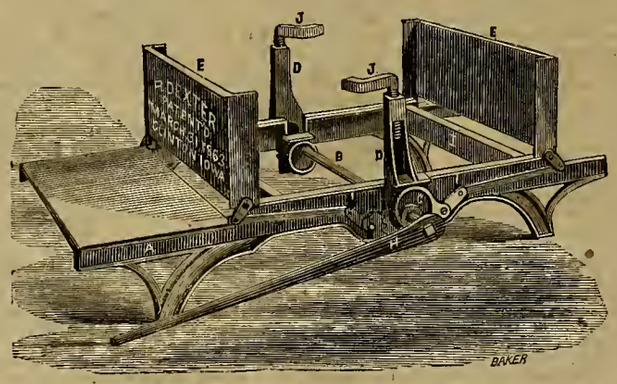

FIG. 2. DEXTER'S PATENT SHINGLE PRESS AND BUNCHER.

Improved Shingle Machinery.

In our accompanying engravings on this, as well ss on page 329 of this issae, are illnstrsted machines for the manufacture of shingles and beading by the most modern, rspid and economical methods. With the growth of tha conntry and constsnt increase in the amount of bailding annnslly undertaken and trade carried on, it is necessary thst the processes by which the materials for such enterprises are furnished shonld be correspondingly improved, else the supply would very soon fall hopelessly behind the demsnd. Fortnnstely, by an irresistible law of nature, these matters are almost perfectly self-regulating, and the need of new mschinery or devices for any purpose speedily calls into exercise the skill required to meet the emergency.

In Figure 1 is shown a twelve block rotary shingle machine, Evarts' patent. It consists of a frsme about seven feet square, having on esch of two sides an upright shaft carrying a horizontal saw, while shove the saws is mounted a circulsr csrriage, some eight feet in diameter. The csrriage is divided into twelve spaces, and while it is ia motion a block to be cnt into shingles is placed in each space. As fast as the blocks are worked up, new ones are snpplied. The two friction rollers which drive the carriage give a steady and uniform feed snd prevent bscklasb. The motion is positive and continnous, there being no springs or other gear to get out of order. The dogs are simply weights raised by an incline plane to drop off the end and fasten the block while the saw is passing through. It is claimed that this machine will saw donble the quantity of shingles in a given time that csn be turned ont by an ordinsry two-block machine, and four times as many as any hand-fed one-block apparatns. Its capacity, with two saws, is stated at 20,000 shingles per honr, or 150,000 per dsy, in ordinary white pine or cypress timber; with one saw, 75,000 per day. It will saw shingles from 16 to 18 inches in length, sawing tbe blocks np as close as any other machine, leaving very small slabs or spalts, and making scarcely any clip shingles. One man csn perform the work of placing the bolts in the revolving carriage, and a hoy can easily remove the slabs from the opposite side. No danger or loss of time is inourred in taking ont, tarning, or replacing the holts, as they are nndogged, except when nassing over the saw. The tables heing fixed in opposite directions and not tilted, the shinglos are mado evenly as well as smoothly, and if the blocks vary in leagth the shingles do not vary in thickness.

Fignre 2 represents a very useful, ecoaomical and neat machine for hnnching shingles. With this simple machine a suitable number of shingles may readily be adjusted and compactly bound together in a neat and convenient bnndle so they csn be easily bandled and safely transported. In this machine the pressure is applied at both top and bottom of the bandle, thereby preserving the shapa of the bnndle and firmly hinding them together. By means of this improvement *inexperienced* hands and hoys can bunch shingles quicker, neater and more completely than experienced bunchers can without its aid.

Messrs. C. S. & S. Bnrt, of Dunleith, Ill., are tbe manufacturers of the machines above desoribed, and in fact of every kind of machine required in the manufactnre of shingles and heading. In addressing inquiries to them, onr read-rs will oblige us hy mentioning this paper as the source of their information.

THE Humboldt mill and mining company are making regular shipments of bullion two and three times a week,

Lower California Mines.

David Turner, the American consul stationed at La Paz, recently arrived in this city on the Colorado River steam navigation company's steamer *Montana*, and furnishes the *Bulletin* some very interesting information on matters connected with Lower California. He is enthusiastic in his account of the condition and prospects of that isolated Mexican province. The popular idea that Lower California is barren and unproductive is, according to Mr. Turner, altogether erroneous. While there are large tracts of land which are incapable of producing any agricultural products, and contain, so far as known, no mineral wealth, there exists enough arable land throughout the province to support a very large population, and capable of producing corn, sugar, tobacco, rice and tropical fruits. Although the rainfall is light and flowing streams not numerous, water is obtainable in large quantities at a depth of from twenty-five to thirty feet, which can be used for irrigation through the agency of windmills or other pumping apparatus. In some parts of the province, as for instance at Todos Santos, an abundant supply of water is obtained for irrigating purposes from natural artesian wells, from which voluminous streams emerge. There is a tract of about one thousand acres thus cultivated at Todos Santos, on which heavy crops of sugar cane are being raised and manufactured into panoche.

The Silver Mines of La Paz.

The city of La Paz, the capital of the province of Lower California, is dependent upon the pearl fisheries of the Gulf of California and the products of the mining districts in the adjacent mountainous regions. The silver mines in the vicinity of La Paz not only hold out well, but the ledges increase in width and the ore in richness with the increase in depth of the explorations. The Hormigum mine, in which some leading San Francisco capitalists are interested, is now producing a larger quantity of ore than it has ever done before. For some time the production of the mine has been much greater than the capacity of the mills to reduce, and an immense quantity of ore has accumulated on the dumps. At present there are between four and five hundred men employed in the mine, the force having been relieved to give the mills an opportunity to catch up. A new process of reduction, known as the lixiviation process, is about to be introduced, which is much more thorough than that of the pan and barrel, which has been in vogue heretofore. By the lixiviation process no quicksilver is employed, and the silver obtained is 100 fine, finer than that obtained through the old process, while the percentage of metal extracted from the ore is much greater. The lixiviation process has been used with success throughout the silver mining districts of Mexico, where the ores are rebellious, like the ore of the Hormigum mine, in which the silver is combined with antimony, zinc, and other metals. The new process has also the advantage of being much cheaper. The greatest depth reached in any of the mines in the vicinity of La Paz does not exceed four hundred feet, and the ledges vary from four to ten feet in width.

Ore-bearing ledges have been discovered recently near Cape St. Lucas, and a company of prospectors left this city for the new mining district, with a view of thoroughly testing the ledges.

The New Copper Mines of Mulega.

The copper mines of Mulega are represented by Mr. Turner to be looming up. During last year the shipments of copper ore from these mines aggregated 6,000 tons, which would average twenty-five per cent. copper. These mines are paying well, and the exports to England will be much greater this year than last.

Orchilla.

The orchilla business is in a flourishing condition. Between 3,000 and 4,000 tons of this commodity, most of which was gathered at Magdalena bay, has been shipped thus far this year to England. Some of the orchilla is shipped direct to its final destination; but a considerable quantity is forwarded to San Francisco for transhipment. Large quantities of orchilla are gathered in the immediate vicinity of La Paz. The business is at present in the hands of Joseph P. Hale, of this city, and Cobos & Monroy of Ecuador. There are between 200 and 300 men employed in the work of picking and baling for shipment. The average price of orchilla at Liverpool during the past season has been $160 per ton. The supply along the Lower California coast is said to be inexhaustible, and the quantity now gathered and shipped from La Paz and Magdalena bay is sufficiently large to control the market.

Towers and Bells.—Six months after the completion of a tower bell-ringing may be safely allowed, as the mortar would have sufficiently set by that time. If the framework of the belle is constructed independently of the walls of the tower, resting on corbels instead of being inserted in the walls, the vibration caused by ringing would have little or no injurious effect.

A New Fish Bait.—A French scientist has invented a new fish bait. A bottle is lowered into the water and lighted by electricity, and the fish are to follow it into a net. But this is a method already employed in the open air over in New Jersey.

California's Financial Condition.

We do not promise any startling disclosures under this heading. No attempt will be made to prove that we are "on the brink of a terrible financial crisis," nor shall we muster into service all the figures and ciphers in the printers' cases, presenting in review a grand army composed of numerical platoons, each of which represents millions of dollars that are apparently impatiently waiting to be "developed" out of "the resources of California." But it must be apparent to every man of ordinary observation that the present financial situation of this portion of America is a peculiar one. The East, South and Northwest have endured several years of trials and tribulations, incident upon, or, to put it more plainly, the natural consequence of *their* way of doing things; and the manner in which they are slowly and safely emerging out of their difficulties is quite as characteristic of their established habits and customs. All honor, say we, to the patient, careful, far seeing men who are thus working their way into clear water, where they may reasonably expect fair sailing for another long term of years. But while we freely grant them this praise, we have no patience with that numerous class of political economists who represent that nothing is financially right in the Atlantic States, only as it corresponds with the English type, and who are just as rigid in their attempts to make California conform to Eastern rules and habits.

Such teachings are decidedly reprehensible. They are ridiculous, but the term ridicule hardly suffices; for the influence, as far as it goes, is dangerous. It distracts the attention of those who give ear to it, and while they are preparing, or at least looking, for troubles almost local, we might say, in their character, they become involved in difficulties to which they have given no thought, but which may properly be considered as partially, if not wholly, climatic.

For California to "right about face," and conform to any Eastern or foreign type, would not be sensible or prudent even. Her situation is not precarious. Even newspaper philosophers cannot make it appear so. Her present outfit of principles and practices is peculiarly suited to the emergencies of her course.

We are not so given over to the worship of agriculture as to be unable to recognize California's indebtedness to the California miner; not only for the gold with which he has enriched her, but for the character which he has stamped upon all other pursuits. This character is in every sense a product of our mines, growing out of their necessities and requirements. It is striking in its outlines and possesses a fineness of detail which is far from being appreciated as yet. Without both these bold and fine points of individuality it could not thus have impressed itself upon the general character of the country. Other callings in California have been rendered particularly impressible by reason of their pursuits partaking more largely of the nature of mining than do the same pursuits in other countries. And if farmers, especially, would realize this, and take the California miner instead of the Eastern or foreign farmer as a guide in industrial operations, it would perhaps be quite as well for them.

There is one great principle of California mining which even now constitutes a vital organ in the system of California farming. We allude to the faith—not blind, nor yet demonstrated—which does not hesitate to invest labor and money in the possibilities of the gravel bed, the quartz ledge and the farm. Without this faith and this willingness to "take chances," neither the mineral nor the agricultural wealth of this country would have been developed.

This faith has not only sustained the miner and the farmer in their labors and ventures; it has led the merchant, banker and manufacturer to contribute of their goods in aid of these great industries. We see no indications of a weakening of this faith in any quarter, and we look upon this as the saving power which will carry us through any difficulties that may seem imminent.

For any one to deny that money is at present unusually scarce in California, or that credits are restricted, would be an indication of foolhardiness, to say the least; and to say that this condition of things is the result of the withdrawal of confidence in any of our resources would be quite as discreditable to his discernment.

Agricultural enterprise, as usual, needs credit. It is well known that certain sources upon which it has largely relied heretofore, are at present closed against it; but we do not apprehend that the farming operations of the coming year will be perceptibly crippled on this account. Other sources of credit will be opened; for, to the living faith in the wonderful possibilities of our farms, and in the ability of their owners to reduce them to certainties, is added the assurance that millions have been added to their value by way of tangible improvements, constituting the best possible security.

Bankers and merchants in the mining districts are free to admit that it is not considered "good business" to withhold their accommodations from prospectors and owners of undeveloped mines; for the parties asking accommodation may in the course of a few months become bankers and merchants. The same turning of the tables is liable to occur in the agricultural districts, though less suddenly perhaps.

Although we do not anticipate any further demands for accommodations on the part of our farmers than legitimate business would supply, we do not doubt that favors, even in advance of this, would be duly appreciated and would undoubtedly meet with a suitable return.

Los Angeles Homes and Enterprises.

[From Pacific Rural Press.]

Messrs. Editors:—Whenever one visits Los Angeles, breathes its pure invigorating air, enjoys its equable and genial temperature, and looks upon its beautiful orange and other orchards, he cannot wonder at the enthusiasm of its fortunate people, when they speak of its varied advantages. It is, indeed, a charming portion of our splendid State.

The yield of their specialty,

Semi-Tropical Fruit,

promises this season to be larger than ever before. Their English walnut crop has been diminished by the heavy frosts of last spring, just as were our peaches and almonds. Yet a considerable quantity of these are being shipped. Col. Ed. Kewen, who has near San Gabriel Mission, some sixteen miles from Los Angeles, one of the best and most beautifully improved ranches of the State, had shipped over eighty sacks of these Madeira nuts, before the end of October. It so happens that this place has a fine southern exposure, and is protected by a ridge from any cold and blighting winds of the north and northwest. It is, for these reasons, less subject to hurtful frosts than some other localities in the county.

In truth, when any wish to see a rare type of utility, beauty and general attractiveness, embraced in a well regulated farm, let them visit Col. Kewen's home in San Gabriel valley, and we can safely say they will realize some of their ideals of a life time, when riding or walking over his 400 acres or more. It has fallen to the lot of the writer to visit many of the finest ranches of California, places which well deserve their wide spread reputation, but in no other one place has he seen such a variety of attractive features combined in charming array as within the moderate limits of this

Model Farm.

Besides his fine supplies of barley, corn and vegetables, think of his avenues and groves of most beautiful orange trees, over sixteen years old, and some of them loaded with four thousand oranges. Think of the profusion of lemon, lime and Madeira nut trees in full bearing, his large vineyard loaded with grapes, his miniature fish pond and lake, his nursery of young trees, including even the hickory and pecan trees of the Southern States. Picture to yourselves the beautiful approach by winding and well graded "walks" to an old castle-like home, embowered in trees and trailing vines; on each side of you, handsome and fragrant flower beds; here and there a tall and graceful olive tree full of ripening fruit; occasional orange, lemon and lime trees with their rich glossy leaves, and golden burden; even a date palm growing near by and ready to hear, and testeful arches of rose bushes, under which you pass just before entering the hospitable mansion. It is, indeed, as nearly like an enchanted scene as any you can witness in America.

And when you remember that the surface is rolling enough to give a pleasing variety, and that the eye looks upon all these charming objects through a crystal atmosphere as pure and clear as any that Italy or Eastern lands can boast of, while you see at no great distance the mountains towering 5,000 feet high, which help to give us this pure air, you can understand that as you feast your mind on so rare a combination of the beauties of nature, you seem for the time to be almost lost to material existence, and to have suddenly passed into such a scene of beauty and luxury as we find described in the Arabian Nights.

The Old Mansion

Itself is a remarkable one. Its adobe walls, six feet through, were erected about a century ago by the old padres of San Gabriel Mission. At one corner of the building, from an arched structure, several feet in diameter, runs a stream of clear, pure, cool water from a natural spring. The walls now stand much as they were left by these early Jesuit founders of our Missions, so that, to its many attractive surroundings, is added the charm of antiquity, and that too, in a State looked upon until recently as so new and wild.

Nov. 9th, 1875. J. W. A. Wright.

The Language of Colors.—The following is said to be the French method of the meaning attached to colors, but it appears to us to smack rather of the laboratory than of genuine sentiment. They hold out that violet is analogous to friendship, blue to love, as suggested by blue eyes and azure sky. A bunch of violets would, therefore, tell a lady's suitor that friendship is all that he has a right to expect. Yellow is paternity, or maternity; it is a yellow ray of the spectrum which causes the germ to shoot. Red signifies ambition; indigo, the spirit of rivalry; green, the love of change, fickleness, but also work; orange enthusiasm; white, unity, universality; black, favoritism, the influence exerted by an individual. Certain persons have the gift of fascinating all who approach them; and black, which absorbs all the rays of the spectrum, is the reverse of white, which combines them in one. Besides the seven primitive colors, gray indicates poverty; brown, prudery; pink, modesty; silver-gray (semi-white), feeble love; lilac, (semi-violet), feeble friendship; pale pink, false shame.

A Mining Swindle.

The Sacramento *Bee* of the 11th inst. says: Wm. Garrison, a gentleman lately arrived in this State from Southern Kentucky, and who returns to-day to his home in the valley of the Mississippi, relates a sad tale of the vanity of human expectation, and the prevalence everywhere of moral turpitude. He tells the following story of his experience, in the hope that it may prevent others from falling victims to similar wiles: About six years ago, Alex. Wilson, an old classmate of mine, left our neighborhood and came to California. For a long time we heard nothing of him; but two years since he began to write to his acquaintances at home that he had gone into mining extensively and was in a fair way of making a fortune. This pleased and piqued all his neighbors, and while many of them sold out their farms and left for the land of gold, those who remained at home were anxious to get an interest in a gold mine. Meanwhile the letters were coming regularly from Wilson, until at last he announced his final triumph, and declared his intention of returning to

Visit the Scenes of his Childhood,

The friends of his schooldays, etc., and about six months ago he put in an appearance at Hickman, where he spent some time in circulating around. As he was very free with his money, the innocent country people believed that he had struck it rich, while his glowing account of future prospects made them desire to share his luck. According to his assertions the Bank of California or the Pacific railroad would be nothing in a few years compared to his wealth. He claimed to have the richest mine on the coast, but was willing to let his friends have an interest in the enterprise, as it was big enough to give something to everybody. Thinking that this was an opportunity which could offer but once in a lifetime, a number of the farmers in that vicinity clubbed together and purchased one-fourth of the Raccoon ledge, in Inyo county, and chose Mr. Garrison as trustee to represent them in the company. As soon as the arrangement was effected and the money paid in, Wilson announced that it was necessary for him to return to California to attend to some business connected with the mine, and asked Mr. Garrison to accompany him, which invitation the latter gladly accepted. When they arrived here Wilson took the new trustee to the company's office at San Francisco and introduced him to another gentleman, who was supposed to be the superintendent of the mine. This individual informed Wilson that his arrival was opportune, as the water had commenced coming in on the workmen and nothing could be done until pumps and machinery were erected, and that the improvements would cause a considerable outlay. After the subject was discussed, it was determined that

An Assessment Should be Levied

At once in order to get the mine in working order again. When news reached Kentucky that the shareholders must pay an assessment instead of receiving a dividend, considerable surprise and dissatisfaction was expressed, but this all wore away under the assurance that the money would all be paid back, with interest, in the course of two or three months, as the ore was there and nothing remained for them to do but to extract the metal. The Kentucky stockholders paid up their assessment, and Wilson went to the East to purchase the pumping and hoisting apparatus, Mr. Garrison remaining at San Francisco in charge of the company's affairs, while the superintendent left for Inyo county, in order to look after the mine and see that everything was in readiness to commence operations upon the arrival of the machinery. After these officials had been gone some three weeks, and no letters had been received from them, Mr. Garrison began to feel a little uneasy, especially as a bill for two months' office rent had just been sent to him and he could nowhere find company funds with which to meet the demand. He settled the account out of his own private purse, but not without some misgivings that all was not right. Although he visited the postoffice daily for a couple of weeks longer, he failed to receive any word from the absent parties. At last he determined to go to Independence and learn the true state of affairs. Upon arriving there he was horrified at discovering that

There Was no Raccoon Ledge,

And that the men he spoke of were entirely unknown in that neighborhood—in fact, that he and his friends had been swindled. He returned at once to San Francisco, made inquiries about the missing operators, and found that he had undoubtedly been sold. Becoming convinced that the swindlers had gone to parts unknown, and having no desire to spend money simply for the sake of punishing them, he concluded that the best thing he could do under the circumstances would be to go back to the bosom of his family. As he had not the slightest hope of recovering the stolen money he would not waste time in an endeavor to bring the confidence men to justice, and thus another pair of graceless villains are allowed to run at large. Mr. Garrison knows of only $20,000 which they secured as purchase money and assessments, but seems inclined to believe that the total amount of their steal will reach a much larger sum, as he has reasons for thinking others were swindled in the operation as well as his friends.

A Useful Rule.—Three times the weight in pounds per fathom equals the working load in hundredweights of good hempen rope.

SCIENTIFIC PROGRESS.

Solar Disturbance and Rain.

The apparent size of the sun, as demonstrated by Secchi in Italy, varies in such a way that when the diameter is smallest, the number of spots and protnherances is largest. The spots seen on the surface will, when turned toward the edge of the snn by its revolution aronnd the axis, show protaherences above them, They appear in tha greatest nnmber along and aronnd the solar eqnator and are scarce at its poles. The appearance of these spots and protnberances above them indicate great solar storms, and these are of a violence of which we on our quiet earth can form no conception. Imagine jets of incandescent hydrogen ef 100,000 miles high projected out of the dark opening in the solar atmosphere which forms a spot. Snch a so-called dark spot is in faet not dark at all, possessing as it does a luminosity greater than white hot iron; it is only dark if compared with the intense lnminosity of the rest of the surface of the solar orb. If, dering a solar hurricane, oat of these spots or holes the aun is ejecting hydrogen, its diameter diminishes; when free of spots and comparatively calm, its diameter is larger.

It has been snggested that this ejected hydrogen could reach onr earth, and he the cause nf rain-storms here; bnt when we consider that onr distance from the sun is a thoasand times the greatest hight reached by this ejected gas from the snn, and that the solar gravitation at that hight is over twenty times greater than the gravitation to onr earth on its snrface, and a thousand times greater than the attraction of onr esrth to the moon, it is olear that there is no possibility of this gas reaching us; aad the cause nf tbe recent rains must he looked for among complicated disturbancea in our own atmosphere, of snch s natnre that simply some regions got more rain at the expense of others which got less.—*Ex.*

The Electric Light in Telegraphy.

The roof of the Siemens-Halske factory at Berlin, was recently the scene of a seriea of experiments with the electric light, which filled all the streets in lhe vicinity with a crowd stariag with astonishment at a snpposed wouderfnl natnral phenomenon up in the clonds. The apparatus, which gave a light so powerful that ordinary writing could be read by its illnmination at a mile distance, was arranged with an inclosed mirror, so that the rays were projected against the clouds, which served as a screen. In front of the mirror the signals were made, and these were repeated, of conrse on a gigantic scale, in the olouds.

These experiments will be read with interest in connection with an article in the adjoining column, under the head of "Solar Telegraphy." For military, snrveying, and other purposes it is otten found desirable to commnnicate between distant atations where there is no electric telegraph; and it is by tbe use of snch means as are described in these two articles that such a desidcratnm may he accomplished, the mode described above being applicable to night telegraphy, and the other for day. Both devices are now being adopted in the military aa well as civil services of the different European governments, and to some extent in our own; and may very properly he classed among the progressive steps of practical science.

METALLURGICAL FURNACES.—Mr. A. Parkes, of Erdington, England, has devised a furnace which consists ssentially of a chamber or generator in which gaseous fuel, consisting mainly of earbonic oxide, is generated, the gaseous fuel being conducted over a hollow bridge or hot air flue into a reverberatory chamber in which copper is smelted, or the pnddling of iron or other like metallurgical operation is carried on. The hot air from this bridge or fine, mixing with the gaseous fusl, effects its combustion and produces an intense heat in the reverheratory chamber. The air supplied to the hollow bridge or hot air flue is heated hy passing through the walls of the generator, whieh are reticnlated or honeycombed. The waste heat from the reverheratory chamber may he utilized hy being passed to a second or cementing chamher, and from tbence to a boiler for the generation of steam. The gas generator and hot air bridge may be applied to steam boiler and other furnacee unconnected with metallurgical furnaces.

PRECIOUS STONES ARTIFICIALLY PRODUCED.—The oxide of alaminium-hae long heen known to chemists to constitute, in crystalline forms, the sapphire, ruby, emerald, etc., and it was rightly concluded that the discovering of practical meane of isolating and crystallizing alumina wonld make the production of all manner of geme, with few exceptions, ont of the mud of any olay conntry road a very simple bnsiness. The different colors of the natural geme—red, green, purple, etc.—come from the slight admixture of other metallie oxides, as of iron, snlphur, etc., the easiest thing to do. It is claimed that this remarkable discovery hae bsen made. It was recently made the anhject of a most lucid and satiefactory address of Prof. Archer, hefore the Royal Scottieh Society of Arts, Edinhurgh. A Parisian chemist hae artificially prodnced all gems of whioh oxide of aluminium is the constituent.

Solar Telegraphy.

It is a matter of common observation that the rays of the snn are brilliantly reflected to enormous distances from glass huildings or from polished surfaces. Take, for instance, as a familiar illustratinn, the san's rays, falling npon a ridged roof at a snitable angle, when they are reflected many miles away and are clearly visible even when the huilding is only dimly discernible through miles of intervening smoky atmosphere.

Considering this, it might appear somewhat remarkable that advantage has not heen takea of the circumstance to found a system of telegraphy thereon. Not that such a system could always be relied upon for use in climates where sunlight is capricious. Bnt in countries where snnshine is not so fitful such a system would serve the most useful purposes. As a matter of fact, the rays of the sun have heen utilized for signalling purposes at intervals for centuries past. The fleet of Alexander the Great is said to have heen guided slong the Persian gulf hy mirrors, on his returu from invading India. On the prairies, too, the Indians still carry on signalling hy means of snn flashes, and a similar method was adopted hy the Russians at the siege of Sebastopol. Bnt the principle appears never to have heen reduced to a system; arhitrary sigas have been hitherto made to work ont a perfect code of signals and to devise an instrament of apparatue which shall represent them.

Sun-flashing has, however, been of essential service in extensive surveying operations, although even there it is only made to convey very limited information—to signal only, in fact, and not to converse. Towards the close of the last centnry General Roy was engaged in connecting the meridians of Paris and Greenwich, and he employed sun-flasbing in his operations. Later, in the early years of the English trigonometrical survey, Bengal lights or Argand lamps were burned at night on the distant points, the hearings of which it was desired to take. But this gave a very limited range and involved other practical difficulties, which led to the invention hy Captain Drnmmond of the light which hears his name. This enabled ranges of from thirty to forty miles to be obtained; even these distances were soon exceeded when, in 1822, Colonel Colby designed an apparatns for signalling hy flashing tbe snn's rays, which proved very successful. Snbsequently Captain Drnmmond improved upon Colonel Colby's instrument hy the iuveation known as the heliostat, which was an instrnment consisting of an adjustable mirror as a reflector, worked in connection with a combination of telescopes. This apparatus, at first somewhat complex, was afterwards greatly simplified. Professor Gauss also introduced a similar instrnment, which proved of great service in facilitating the work. The heliostat is now a recognised adjunct of all trigonometrical surveys, and by its aid triangles having sides of 100 miles in length have heen formed even in Great Britain—notably that formed hy Sca Fell in Cumherland, Slieve Donard in Ireland, and Snowdon in Wales, the sides of which are respectively 111, 108, and 102 miles in leagth.

But the heliostat does no more than permit of an arhitrary set of signals heing exchanged; it does not allow a conversation to be carried on. To hriag the beams of the sun into subjection in this respect and to utilize them as a means of freely interchanging ideas was left for Mr. Henry C. Mance, of the Government Persian Gnlf telegraph department, to accomplish. This he has succeeded in effecting hy means of a very simple apparatns, which is known as tbe Mance heliograph, or sna-telegraph, which aonsists of a light tripod stand aboat foar feet long when folded up for transport. On this tripod is screwed a circular mirror, varying in diameter according to whether it is designed for field or fixed observations. If for the former purpose the mirror is abont four inches in diameter; while if for the latter it is ahout nine inches. The mirror is hung in a frame so as to revolve ahout a horizontal axis, and it is adjnsted to the reqnired angle of incidence with the snn hy means of a telescopic connecting rod. The horizontal circular traverse of the instrument is obtained hy means of a tangent screw gearing into a small horizontal wormwheel, with the center of which the mirror is connected. By means of the tangent ecrew and tbe vertical ecrewed rod, the rays of the sun can bo made to fall npon any given point with the utmost precision. In adjusting the instrument to commence signalliag, the rays are directed to a point slightly before the distant observer'a level, hut npon depressing the connecting rod, tho flash is raised to the level of the observer and he sees it. The observer at the distant station having seen ths bright starlike appearaace in his mirror, sets his instrnment at the point at which they appear, and acknowledges the fact hy signal. If now the longths of these flashes he varied and grouped, they can he made to represent letters, and so worde composing messages can be epelt ont, precisely as is done hy sound reading with the Morse alphahet.

LIGHTNING *vs.* COLOR.—A Scotch granite monnment at Cambridge City, Indiana, was recently struck hy lightning, the current following the shaft to the limestone hase, taking ont every particle of red color, and leaving a white zig-zag strip ahont an inch in width. The monnment was not injured. The color, no donht, consisted of mineral paint which was a good conductor of electricity.

MECHANICAL PROGRESS.

Cleaning Steam Boilers.

A correspondent of the *Colliery Guardian* says:—Boilers are much easier to clean, and give less trouble when allowed to cool down gradnally. A thin scale, say ahout the thickness of a coat of whitewash, is a valnable preservative of the plates, and is often produced artillcially to protect boilers which are intended afterwards to work with water, from surface condensers. The apparent corrosion caused hy the scale is really dne to the damage caused hy the scaling hammer or similar means nsed to remove the incrustalion. Take a hoiler plate, snd ent or scratch through its natnral "skin," and leave it exposed to the weather for a short time, and the parts thus damsged will he fonnd very much more corroded than where the natnral protection is left on. Next, examine the interior of a hoiler which has heen "sealed," and the surface will he found partly protected hy a thin scale still adhering, hnt scarred and nicked in namerous places hy tho chisel or hammer employed, Every one of these places is a nucleus for corrosion.

But there is a still more importantreason why boilers shonld not he hlown off until cool. The nneqaal coatraction caused hy the snlden changes of temperature exercise a most iajurious effect on the boiler, and is a frequent cause of scam rip. Some years ago, when I had some fifty egg-ended hoilers ander my charge, I was much troubled by those in one particular groap, where seam rips, often extending half roand the circnmference, were of frequent occarrence. Suspecting that the practice of hlowing off while hot was at the bottom of it, I taxed the stoker with it, hut was met by a positive denial. Soon afterwards, I detected him in the act of hlowing off the momeat the fire was drawn and then settiag opon the damper and fire doors, thus passing a carrent of cold air directly nnder the hoiler. As soon as the boiler was fit to enter I discovered, as I expected, a very fine specimen of seam rip. After this the practice was pnt a stop to, and though no other change was made in the workiag of the boilers, I had no more trouble from seam rips, while the facility for cleaning out far counterhalanced the loss of a few hours before tbe boiler could he again set to work.

Though scale does not "eat into" the plates of a hoiler, it is a fraitful source of damage to them through rendering them liable to he overhoated. This may be specially noticed in the fire-hox plates of locomotive hoilers.

In conclusion, I wish to draw attention to the corrosive action of damp mortar in contact with hoiler plates. I could name several iastances in which I have noticed a slight leakage from a pipe or other fitting into the hrickwork snrrounding a hoiler, and have subsequently fonnd when examining the hoiler internally, that the plating at that point was so thin that a hole conld he knocked through it with a very few hlows of a hammer. No mortar shonld he used in coutact with a hoiler; hut fire-clay, properly prepared, should be substituted.

Cement Walls in Salt Water.

Great consternstion was recently causcd among the dock commissioners of New York by the discovery that the supposed "great improvement" in the mauner of constructing cement walls on the river front, introduced by the late chief engineer, General Graham, is a lamentsble failure. Some of the new halkheads, after an examination from beaeath by sahmsrine divers, were discovered to he ornmhliug in pieces, threatening the whole work with speedy destruction. It is only a few weeks since General Graham presented to the commissioners a most encouraging report of his success with the aew system. Instead of lowering costly and cnmhersome blocks of stone by the aid of expensive derricks and machinery, he built up great monoliths of heton concrete *en masse*, manufacturing it on the spot. Tbe saviug in expense by hnilding on this system was said to he $67.77 per foot rnn, or over $350,000 per mile. The discovery that the wall is grsdnally being disintegrated came upon those in charge most nnexpectedly, just as they were congratulatiag themeolves npon the entire success of the new system. Work was immediately stopped, and the new engineer, Mr. G. S. Greene, Jr., made a carefnl examiaation which satisfied him that the plan of huilding bulkheads of conerete placed under water *en masse*, can not he depended npon. The mayor immediately appointed a board of engineers of high standing in their profession to examine the work, and we may expect within a few days to learn what coarse of aetion will be pnrsned.

PAPER WATER BUCKETS.—The real possihility and advantage of the varied and extending usos of paper pulp are illnstrated in the manufacture of such articles as water pails, barrels, etc., which are now made in large nnmhers of this material. In the old way of making pails, the separate parts or staves are cut, one at a time, from a log of wood, and in making them, all the chips and smaller pieces are wasted, so far as the real object of the mannfactare is concerned. In making a paper pail, the fibrous material is wholly ntilized, and if the original stock is wood, as in part it may be, then that which would he wasted in chips and fag ends is entirely saved. Those who make paper tell us that they have thus far barely entered on some of their new lines of product.

Furniture Manufacture.

To one familiar with the furniture trade of this country, its change and growth within the past twenty years must seem wonderful indeed.

It is only about twenty years since woodworking machinery began to he used; at first quite rude in constrnction, and fitted only to perform the rougher portions of the labor of a cabinet factory, bnt improvements were made with each succeeding year, and now there are one or more machines adapted to each of the several parts of the cabinet work of all articles of furnitnre; and no manufacturer for the trade, of the smallest pretensions, hut runs several of these labor saving inventions.

The snbstitution of these skilled appliances for manual mechanism has tended to greatly increase the production of furnitare of all varieties, and a shop employing fifty hands with a proper outfit of the "most approved machines" can turn out a stock of goods in one month that would have heen a year's work tor the same hands without machinery. Dariag the latter years of the war and for the immediate succeeding seasoas the supply was hardly eqnal to the demand; and under the influence of this lively demand at heavy profits, large cabinet factories were built on every hand, and machinory was utilized that would accomplish the labor of half a score of men.

An article of furnitnre not being needed fresh every season, as a hat or cost, the general depression of trade has necessarily affected this line of business more than many others, and important manufacturers in tho Eastern States with largo aad expensive factories upon their hands, are put to their wits' ends in their attempts to run their bnsiness with profit.

IRON RAILWAY CARRIAGES.—It is believed that the iron safety railway carriage will yet be generally introduced, as a means of alleviating the horrors of a collision when such a cssaalty occnrs. It is well known that the spliaters of an ordinary carriage, when it is smashed, do almost, if not quile, as much harm to passengers as the shock of an accident. In fact, the idea has been snggested, and we think patented in the United States, of employiag papier mache as a constructive material, on the special ground that it would do but little damage in accidents. Mr. Massey, an English inventor, proposes to construct the framework and partitions of a carriage of iron hoops, put together in a manner which must be seen to he understood, hut which reminds us more of an iron bedstead of intricate pattern than anything else. An elastic framework is provided which will certainly withstand a considerable pressure, hut experiment and calculation alone will decide how far it will resist the shock of a collision. Of course, it is to he encased and finished with some other material more pleasant to come in contact with than "cold iron." The inventor, hesides claiming increased safety for this carriage, is confident that it is stronger and more economical than those of the present pattern.

ROLLING STEEL SCRAP.—The Indianapolis *Journal* of October 7th says: "A large namher of iron workers of the city visited the Indianapolis rolling mill yesterday forenoon to witness a new process hy which steel can be welded or restored. A mass of scrap steel was successfully welded and afterwards rolled into a fine steel rail weighing sixty-five pounds to the yard, thirty-two feet in length. Although the rolls were adapted only to iron rails, and the mill hands were not familiar with the process, enough was done to prove conclnsively that the patent flux as applied will accomplish all that is claimed for it, viz: To work up scrap and refuse steel into a merchantable article, and also put worn ont steel rails into a condition that they may be rerolled into rails that are as good as new. The test was highly satisfactory to all who witnessed it, and the managers of the rolling mill are so favorably impressed with the manner the work was done that they will probably arrange their mill to go into the business of manufacturing steel rails on an extensive scale."

IMPROVED ENGINEER'S MACHINE.—This is an ingenious apparatus, which has heen introduced in some of the English workshops with great satisfaction, for trimming off wrought iron locomotive wheels. It is a curvilinear slotting machine, and is mounted in a holder provided at one end of a vibrating lever—the other end of this lever heing slotted and fitted with a sliding block, into which the pin of a disk crank enters. As the crank disk revolves with its upper edge approaching the fulcrum of the lever, the effect of the arrangement is to give the tool holder a slow downward and a quick return stroke. The point of this machine describes, of course, an arc of a circle struck from the center of the vibration of the lever, thereby producing a convex form of the inside of the tire, and so giving additional strength to the rim. The wheel hed plate is revolved by suitable automatic mechanism, somewhat similar to the devices ordinarily employed in planing machines. Provision is made hy crank and screw for wheels of any diameter.

RUBBER TIRES FOR WHEELS.—The movement for the introdaction of noiseless tires for vehicles has been revived in London. In Berlin the experiment is said to have heen entirely successful. The rnbber manufacturers declare themselves able now, by improved processes, to afford a tire cheaper than iron, of longer wear, and in every other respect, of course, much better.

but few cases were known until the first rain set in, and then there appeared suddenly quite a number of cases. No good has yet come to the miner from what has fallen; it only admonishes him to set his house in order, for the winter is at hand and his golden harvest draweth nigh.

CALAVERAS.

WORK BEGUN.—Calaveras *Chronicle*, Nov. 13: There is now water enough in the ditch to admit of the working of two or three hydraulics in this vicinity, and piping is actively going on. Veith, the Tunnel ridge hydraulicer, is piping steadily, employing a large force of hands in and about the mine. The derrick lately put up in the claim works admirably, greatly assisting in disposing of the boulders with which the gravel abounds. During the dry season the mine has been put in splendid shape, and it will give a handsome account of itself this winter. Duryea, proprietor of the famous "Shaw" claim in Chile gulch, is also actively engaged. He has seven or eight men employed in what is known among miners as "bottoming"—in other words working out a depression in the bedrock that cannot be hydrauliced to advantage. The gravel has to be picked, carried into dump boxes and washed. The process is slow, but the deposit cannot be well reached in any other way and the gravel is rich. We understand it is he his intention to resume hydraulicing at an early day. Other claims in the vicinity are in readiness to commence piping and will do so the moment the water supply is sufficiently increased.

MOSQUITO GULCH MINING ITEMS.—Quartz operations in the Mosquito district are, to use the language of market reports, "lively." Work is being pushed with unusual activity for the purpose of getting out and hauling as much rock to the mills as possible before the rainy season fairly opens. At the San Bruno mine operations are progressing finely. Over 200 tons of ore are in the dumps, and a number of teams are employed hauling the rock to Garland's mill. The quartz taken out and now being mined is first grade. Crushing is to be commenced next Monday. Rock is being hauled to the mill from the mine of Herrybausen, Saudermier & Co., located a short distance from the Cold Spring house. The company have out about 100 tons of ore, which good judges say will yield an average of $50 per ton. The stamps will be set at work upon the rock next Monday. The machinery to be erected on the Grasshopper mine is nearly set up, and will be in readiness for use in a few days. Good rock is obtained from the Albers mine, and developments so far made are of the most flattering character. First grade ore continues to be taken from the Rickman mine. No crushing will be done until the stopes now opened are exhausted; then look out for a monster clean-up. Potter & Co., proprietors of the rich vein lately discovered, are again at work taking out rock. Developments are of the most promising nature. Both batteries of Garland's 18-stamp mill will be set in motion on Monday morning next, and there is rock enough out and being hauled to keep them employed for several weeks.

WET POINT DISTRICT.—Pryor & Co. extracted 50 tons of high grade ore from the "Billy Williams," which is now being hauled to a custom mill. Cheeno main shaft is down 102 feet. The bottom of the shaft is now in very favorable looking vein matter, some three feet in width. The rich ore shute lies immediately south. The new main incline of the Josephine is down 40 feet. Building to cover hoisting works completed. Machinery is being put in position. Mina Rica, sinking in bonanza. The Constanoia begins to show up well. Lone Star looks better than ever. The Champion has been enabled by the recent rains to resume work. The usual rich ore is coming out lively. The dumps are beginning to look comfortable.

GLENCOE DISTRICT.—Forty tons of coarse gold ore are available at the Rickman mine. Stopeing. The new hoisting works of the Grasshopper will be completed in a short time. The recent strike in the Joaquin holds out well. The owners of the Good Hope contemplate to resume operations at an early day. Preliminary work going on at the Glencoe Consolidated. A decided, permanent impetus has been given to the district by the excellent results of all the deeper workings.

EL DORADO.

THE DITCH.—El Dorado *Republican*, Nov. 11: We are told that with fifteen days more of favorable weather the new ditch will be completed, and this section assured 5,000 inches of water next season. There will yet be a few weeks' work for 200 or 300 men in enlarging the ditches this side of the main trunk, which can be completed in the spring in season to supply all demands. It is to be hoped that all who contemplate taking water will be in readiness to receive it when it comes, as otherwise it may be so diverted as to render it difficult to secure a supply when wanted. These works have cost an immense amount of money, and no one should complain if the company show a disposition to use the water themselves, if others do not stand ready to take it.

INYO.

CERRO GORDO.—Inyo *Independent*, Nov. 6: It is an admitted fact that the pending case known as the "Big Mining Suit," or the Sao Felipe Co. vs. Belshaw & Co., has a material influence upon times in Cerro Gordo. As it is now passed till another term the prospects for active work on the Hill and consequent lively times are lessened that much, and "that much" is considerable, we are constrained to believe.

THE CUERVO MINE.—This mine, originally located as the Promontorio, Darwin district, is one of the most noted and promising, as regards surface indications and quality of ore, in the district. Its development has been kept back somewhat by threatened litigation, but as all danger from that source is now happily ended, by proceedings in the present district court, work will go on. Mr. G. P. Cornell, superintendent, has been here during the week, and started for Darwin this week. He informs us that he has all the machinery on the ground for the furnace, with lumber for the building on the way, and that he will have the furnace completed and running just as soon as the work can be done, which will be within a few weeks. The furnace will be located at the head of Main street, Darwin, which is about one and a half miles from the mine, with an easy road. Altogether, we think this both an important and gratifying piece of news, and will say that, in our opinion, the Cuervo mining company, the owners of the property, have an excellent boss in Mr. Cornell.

MENDOCINO.

MINE.—Mendocino *Democrat*, Nov. 12: We have been informed from what we deem pretty good authority that the claim of Hagan, Sullivan, Cleaveland and some others, close by the big rock on the new road to Cloverdale makes a promising exhibit for the finding of quicksilver.

NAPA.

POPE VALLEY MINES.—St. Helena *Star*, Nov. 13: We were in conversation with Mr. Dan Patton, the energetic superintendent of the Phœnix quicksilver mine, and we learn from him that the mine had never so good an outlook as at the present time. They have a ledge seven feet thick of good cinnabar, and several small veins, from eight to ten inches in thickness, all good paying ore. Messrs. Staudiford & Wells have bonded their mine to a rich company in San Francisco for the sum of $30,000. We hope they may have good luck and do well; they are both honest, hard working men, and deserve something for the work that they have done in the prospecting line for the past several years.

OAKVILLE MINE.—The Oakville and Bella Union mines are now in a flourishing way, under the able and gentlemanly superintendent, Mr. McQuaid. They are turning out more ore, and more of the pure metal, than ever before in the history of the mine.

THE mine lately located by Mr. John Sellinger, to the south and west of the Bella Union, has proved to be rich in the extreme; and we hear that he has been offered, and refused, $5,000 for the claim as it stands.

NEVADA.

NEW MILL.—Nevada *Transcript*, Nov. 9: We are informed by Jay Parsons that he has completed the contract of building a new quartz mill for Hamilton McCormick out on Gold flat. The mill has eight stamps, and is one of the most complete structures of its size in this vicinity. It has eight stamps, and will be run with water power. It will be used for crushing the rock in the ledge owned by Mr. McCormick. He has 150 tons of rock out and ready for crushing, and it is estimated it will pay thirty or forty dollars per ton. Good judges are of the opinion that Hamilton has got a home stake in this mine. We hope so, for he has labored under difficulties in opening it up and building the mill, that would have discouraged most men. He is deserving of success, and from all accounts he has it in hand now sure.

THE GOLD SPRING COMPANY.—The contractors who have been engaged in running the incline for the Gold Spring gravel mining company, whose mine is located about two miles east of this city, adjoining the Harmony ground, completed their contract yesterday. The incline is now down about 450 ft. The company will now commence a tunnel from the bottom of the incline, with a gradual raise, in order to strike the pay channel, which runs under the ridge. This work they expect to accomplish in two or three weeks, when the course of the pay channel will be fully determined. A number of claims located along the ridge are at present idle, waiting development from the Gold Spring company, and as soon as the direction of the channel is known, work will be commenced on all of them. So that considerable importance is attached to the working of the Gold Spring mine, about this time, by those who own claims on each side. Messrs. Isoard, Rolfe and others are the owners of this mine, and their perseverance entitles them to reward for their labor, which we hope and believe will be a golden harvest.

WE hear of several new prospecting companies being formed in this and Grass Valley townships, with a view to test some of the numerous ledges with the Fryer process. There are hundreds of them that will, without doubt, pay if all the gold in the rock can be saved.

THE survey of the new ditch which is to be run from the South Yuba to Smartsville, is about completed, and the projectors propose, if possible, to have it completed by June next to Indian Springs, where it will connect with one already running to the mines at Smartsville.

PLACER.

THE SEASON.—Dutch Flat *Forum*, Nov. 11: The rain has been falling copiously yet gently for about two weeks, and the rainy season may be said to have fairly set in for the season, and the prospects for a continuance until the earth becomes saturated is flattering. So that the supply of water to fill the ditches for miners' uses will soon be abundant.

PLUMAS.

GOOD RESULTS.—Plumas *National*, Nov. 6: The Indian Valley mine, near Greenville, has recently been turning out some first-rate rock, and the last two runs of the mills have been "eminently satisfactory." Messrs. Whitlock & Hall have the mine in charge at present. The Major was in town on Monday evening, and showed us a bar of bullion worth $3,100, the result of twelve days' run of the mill. The twelve days preceding this netted $2,630. There is plenty of the same kind of rock in sight, and the prospects are first-rate. We are glad these gentlemen have made the mine pay, for it has been on the "non-paying" list for a long time before they took it, and as usual, there were plenty of "croakers" to predict that they had a bad speculation on hand.

FALSE REPORT.—A report was in circulation, a few days ago, to the effect that a portion of the new Caribou ditch had slid or caved away, and the rumor stated that about a half-mile had gone down the hill. We are glad to be able to contradict the story, and we have it on good authority that only a very slight break occurred, and that the damage has been already repaired.

SIERRA.

A BONANZA.—*Mountain Messenger*, Nov. 6: Van Wagner and Eastman recently found some very rich rock in Caribou ravine. Not long since they took out, in one day, upwards of $1,000 worth of gold.

ORO.—Rich rock has just been struck in the Oro.

WATER.—The Bald Mountain company got a little water during the late storm, amounting to three or four reservoirs per diem for a few days.

SISKIYOU.

WILL SOON BE READY.—Yreka *Union*, Nov. 13: The mill of Cornish & Co. is expected to be ready to start up the coming week. E. Ramons, who was over making the wheel and otherwise repairing the mill, got through on Saturday, and ere long the thump, thump of the stamps will be resounding through the canons of Humbug, and coin will jiggle in the pockets of the fortunate owners, and their workmen.

TRINITY.

WATER SUPPLY.—Trinity *Journal*, Nov. 13: There was some water in the ditches hereabouts during the rain a few days ago, but when it stopped raining the water stopped. There is no water for sluicing yet, the only beneficial result from the rain being that it soaked the ground some. The present season commences just as the last did, but we will have more water and a better winter if the united prayers of the placer mining fraternity avail anything. Miners have their claims in good condition and with a reasonable water supply good results are anticipated.

TUOLUMNE.

GOLDEN GATE.—Tuolumne *Independent*, Nov. 13: At the Golden Gate extensive works are contemplated. Several new Hendy concentrators are on the road and will be put in next week, in addition to those already in use. Experiments made during the past summer justify these improvements. If these are a success, as is confidently expected, the company intend to erect new hoisting works, put up chlorination apparatus, enlarge their dam, and make other additions to their valuable property, which will enable them to work their mine on a large scale. At a depth of 200 feet they find rock worth $30 per ton, rich in sulphurets. Mr. H. G. Wetmore has been recently appointed superintendent, and we believe the Golden Gate will prove all its many friends hope for.

THE water in the Tuolumne Hydraulic M. Co.'s ditch has been increased seventy-five inches by the late rains. The company have been making repairs on their lower dam, and everything up there is now in fine condition. Next week they will commence repairing flumes on the line, which will take about two weeks. M. B. Harriman, the general agent, and local agent on the Sonora and Shaw's Flat line, is an energetic, live man, just such an one as a work of this kind needs.

THE Dry Arroyo gravel claim is being reopened under the management of Mr. James Parsons. The company propose sinking a shaft where they left off last season—at which place it paid 5 or 6 ounces a day, some days working but 4 or 5 hours.

JAS BURNS & Co. cleaned up in the Main gravel digging last week $261. Mr. Burns said it was a small week's work, and didn't care to have the reporter notice it. Those poor divils in large cities with nothing to do this winter, on short allowance, would consider it a "big week's work," were they fortunately thrown in the way to do it.

THE owners of the Omega Table Mountain mine have secured a United States patent for their 3,600 feet of Table mountain, in this county. Work will be resumed as soon as the rains furnish the necessary water. The company have large deposits of rich gravel, and have run their tunnel 800 feet into the mountain. This claim is next south of the Alpha and the T. M. Blue Gravel.

VENTURA.

NEW DISCOVERY.—San Buenaventura *Free Press*, Nov. 9: Some time since the discovery was made of a large ledge of a mineral somewhat similar to that found in the Ventura soap mine, as it is called. This new deposit is located near the residence of Don Jose Arnaz, about 6 miles from this place up the San Buenaventure river. In appearance it somewhat resembles common soap. It washes well, making a fine lather, and removes all kind of grease and dirt, and is no doubt a valuable discovery. This ledge is a large one, and the material can be easily extracted, for it is mostly above the ground and can be loaded from the ledge immediately into wagons. No doubt it will prove a valuable discovery and one which will add wealth to this county.

Nevada.

WASHOE DISTRICT.

NEW YORK CONSOLIDATED.—The new machinery works as well as could be desired, the water is all out of the shaft, and the bottom being reached once more at the depth of 800 feet from the surface, sinking deeper is about being resumed. At the same time a station is to be opened and a drift started to prospect a promising streak of quartz which was passed through before sinking the shaft was suspended, in order to put in the present new machinery. It gave very good assays at the time, and a deposit of good ore is expected to be found in it. At the 600-ft level work is resumed at a lively rate, advancing the main north drift along the west wall of the ledge. More and more streaks of quartz are met with, and the prospects at this point are very favorable.

LADY BUYAN.—The main north and south drifts on the 380-ft level are steadily advancing. Another cross-cut, No. 2, has been started west, 380 feet south of the shaft, in the main south drift. This cross-cut is now in a distance of 25 feet, the face in fine appearing quartz and ledge matter. The main south drift on the 250-ft level is steadily advancing, without any valuable change to note.

AMAZON AND GLASGOW.—The shaft is sunk 250 feet below the surface, at which point a station has been opened in the hanging wall immediately adjoining the ledge. As soon as the vein was reached the course of the drift was changed northward, and it has now penetrated the ledge a distance of 25 feet, all the way in ore that gives an average assay of $55.60 per ton. The character of the ore is a white sulphuret, free milling and easily worked. Dumps are now being built, and the extraction of ore for milling is to be commenced in a very short time.

CALIFORNIA.—The battery mill is being rebuilt with all the speed possible. Sinking the C. & C. shaft is progressing at the rate of four feet per day. Sinking the winze below cross-cut No. 3 on the 1550-ft level is making fair headway, the bottom still in rich ore. The face of the north drift on the 1550 ft level is steadily advancing toward the Ophir line, still in rich ore. Everything is being done that can be to replace the mine in its former prosperous condition, and there is but little doubt that by the 1st day of January next it will be yielding up at least a portion of its immense treasures, and adding materially to the wealth and prosperity of the Comstock.

SULLIVAN.—Sinking the shaft is discontinued by reason of its being inexpedient to sink deeper with a hand windlass, and the requisite grading for steam hoisting works is now in progress. Meanwhile the tunnel is in 165 feet. Less than 150 feet will bring the tunnel to a connection with the shaft, and, from the assays obtained, a good ledge of pay ore should be found within that distance.

CHOLLAR-POTOSI.—Daily yield, 80 tons of ore, the average assay value of which is about $28 per ton. Sinking the new combination shaft is making excellent headway, the bottom still in soft working material.

IMPERIAL-EMPIRE.—Daily yield, 40 tons of ore, which is taken from the ore stopes between the 1850 and 2000-ft levels. The ore breasts continue to look well. The average assay of car samples is about $50 per ton. The character of the quartz and ledge material encountered in the main drift on the 2000-ft level is much more favorable, and is fast assuming the same looks and make as that encountered on the level above before penetrating the ore body.

YELLOW JACKET.—On the 1940-ft level the drift south, from the bottom of the north winze, is in a distance of 81 ft, the face perfectly dry and still in fair working ground. The face of the north drift, from the bottom of the winze on the 1940-ft level, is in 36 ft, also in dry ground.

JULIA.—The bottom of the shaft is almost entirely in a fine character of quartz, showing conclusively that the main ledge can not be far distant.

BULLION.—The new air machinery on the 2000-ft level is working splendidly, and is making material difference in the progress of the work.

GLOBE CONS.—The south drift from the main west tunnel is steadily advancing, the ledge growing steadily firmer and the quartz of a much better quality as the drift advances to the southward. Some much needed repairs to the shaft are being made.

WOODVILLE CONS.—The stone foundations for the pumping machinery are completed, and the carpenters and millwrights are making good headway on the timbers and frame work of both the building and machinery. The face of the main drift on the 420-ft level is again in hard blasting rock.

LEVIATHAN.—The whole face of the north drift at the 420-ft level still continues in splendid ore, assaying high up in the hundreds. Cross-cutting is to be commenced

(Continued on Page 333.)

History of California Agriculture.

[We give below some extracts from a lecture delivered before the Assembly of the California State University, on Friday, November 5th, 1875, by W. B. Ewer.]

The history of agricultnra in California commences with tha establishment hers of tha early Catholic missions. In establishing a nission, the Fathers took along, among othar things, all the utensils necessary for cultivating the soil; also fruit, vegetabla and flowsr seeds, trees, roots and vines for the orchard and garden, besides a good supply of wheat snd corn, wherewith to seed tha fields. Horses, horned stock, sheep, hogs and poultry, also formed an essential part of thair outfits. Tha first lessons of industry taught the nativas wera thosa counected with agriculture. Thus the aarly missionarias hsre wars tha first farmers iu California—their farming, moreovar, was on quite an extensive scals.

A mission alwsys hald actnal occupancy of a cantrsl tract of choica land from five to fiftaen miles squsra, a small portiou of which only was placed under sctual cultivation, ths lsrger part baing devoted to pasturags. But, thsoretically, ths boundaries of each mission touched ths extrsme limits of its naighbors on the south and north, while east and west tha sea and ths Sierras were the only aoknowledged limits. Afts putting their seed into the ground, a church, a comfortable dwslling, snd a suitshla storahouse wera at onca erected, and for precsution, a oitsdel or presidio was also constructed, which wss garrisoned by a few suldiars in govarnment pay.

Many of these soldiars, whan the tims cams for their discharge, having becoms attached to tha country, sought and obtained the privilege of remaining near tha missions, with permission to cultivate a smsll tract of land and keep a few cattla and horses. They also, as a usual thiug, selected s convarted Indian womsn for a wife. The home govarnment soon began to realiza tha importance of thus ancouraging parmanant settlars in tha country, and building up hara a non-calihata population, of a secular chsracter and with progressiva ideas. To this end it early adopted tha policy of giving a title to dischargad soldiars for snch tracts of land as would enable them to secura for themselves and familias a comfortahla living, aocording to their simpla habits and desiras. It was in this way that land grants originated in California—the first ona being recorded November 27th, 1779, in favor of a soldier at the Mission of Ssn Carlos. In after years this class of settlers was largely supplemented by tha influx of peopla from Mexico and other parts of the world who sought Cslifornia as a dasirable placa of rasidence. The missions wera thus gradually circumscribed in limits and ovarshadowed in nnmbers and political importauce hy the puablos.

The trouhle that had loug been anticipated by tha mission Fathars, finally came upon them in full force in 1834, when by government decree they wera deprived of the greatar portion of their flocks and hsrds, and all but a mere moiaty of their lands, which were held for the benefit of immigrants as they might oome in from tima to time.

Thus in effect was andad tha mission system of Califoraia, which, whatever may hava bsen its faults, at least preparad the way for a battsr oivilization, one more in accordanca with the prograssiva spirit of tha aga, and ona infinitely hettar calculated to develop the agricultural rasources of the country.

Tha stories which ware carried East and to Enrope about this time hy tha tradiug ships whioh visited this coast, created, wherever they were told, a most lively intarest in regard to California. It was pronounced a wouderful country, whara men could live and grow rich without work; whare the cereals, vegetables, the viue, tha oliva, the oranga and other fruits graw and flourished in a most remarkabla manner. It was said that Jacob's cattla in Padan Aram wera scarcely mora prolific than wera tha herds of California. The climate was pronounced unequaled; flowers bloomed all tha year round, and cattle naver raquired shelter or cultivatad grassas. Tha land, in fact, was a goodly inheritance, broad and inviting, aud to be had for tbe mere asking. The affect of these reports was to send great numbers of peopla hera, not only from our own States, but from Europa as well.

It is estimated that thero wera five hundred foraignars in California in 1830. In 1840 this number was increased to over one thousand, while tha half-hraeds numbered about four thousand. In 1846 Mr. Larkin estimated that thera were about two thousand American citizans here, and about six thousand of othar nationalitias, in addition to the half-hreads. Thia would giva a prohabla total population, at tha time the American flag was raisad at Montaray, in July, 1846, of at least fourtaen thouaand, exclusiva of Indians.

The discovery of gold crated a new ara iu the history of California agricultura. The whaat fields woro left to be destroyad hy neglected cattla. Hides and tallow were forgotten, and the ships which ware to have takan away thosa products were doserted by their crews. All joined in the gonaral stampede for the miues. The agricultural interasts of tbe country wera, of course, paralyzed for a timo; but tha check to that industry was merely temporary and preparatory to a new phase of prosperity, such as has produced au astonishment throughout the world, second only to that brought about by tha wonderful discovery which lad to its apparent calamity.

Notwithstanding tha minss constituted tha great magnat which draw thither the teeming thousauds who crossed the ocean and plains in '49 and '50, msny of thosa early comars soon became hsartily tired and discouraged with gold diggiug. Under thess circumstances, many called te miud tha reports whioh thay had heard of the wonderful productiveuess of ths soil of Californis, and resolvsd to ascsrtain, from practical sxpsrience, whathar tha plow and ths hoe would not giva tham a hetter living than could be obtained by tha usa of ths pick snd tha shovel. Accordingly, during tha summsr of 1850 and 1851, scores and hnndreds of littla vslleys in ths foothills of tbs Sierras, and farther np the monntains, aven, were fencad in and planted with vegstables and roots of all kinds. Tha product found a ready sals and high prices at tha mining camps in tha immadiats vicinity. Many also want into agricultursl operations on a larga scala in ths valleys of the Sacramanto and San Joaquin, and in tha old mission grouuds near ths coast, a returu to wheat growing snd cattls raising forming an important portion of tha industry in the valleys. Ths success of thoss who went into sgriculture at this time was most satisfactory, aud such as to induce msny othars to follow their axamplo within tha two or threa succeeding ysars. Tha result of this tillage wss the almost total cassstiou of our imports of vegetables, and an important reduction in that of brasdstuffs—for both of which, on tha sudden influx of population here, we had hsen obliged to rasort to South America, to Oregon aud othar plaoes.

Notwithstanding thera was a comparatively large and constantly increasing amount of wheat and otbar produce raised in California, from 1852 to 1855, the first reliabla report of ths amount of such product commences with the crop year of 1855–6. Tha whaat yisld of that ysar was set down at 5,833,000 bushels, of whioh ws had to spara for export 567,000 hushels. The produotion for the succeeding three or four years was somewhat reduced, in consequence of the continuous drouths of those years; and that, too, notwithstanding there was an annually increasing amount of aoreage seeded. Duriug those yeara we note the singular fact, that whila we ware importing flour in larga quantitiaa we were exportiug wheat in still larger quautities. Tha annual avarage of flour importad was about 20,000 barrels, while the average of wheat exported—when converted into flour—was fully 60,000 barrals. Tha importations ware from Oregon, Chile and New York. We were thus sending our grist a long way to mill; hut the necassity grew out of the lack of mill facilities hera, which wera tardily providad in consequenca of tha high price of labor and mschinery. It was not until 1862 that our importations of flour finally ceased.

From an export of three and a half millions of hushels in 1862, this great source of incoma to the State has gradually increasad nntil it reachad its culminating point of naarly eighteen millions of bushels in 1873, or enough to load about 550 first-class ships! The total yield of wheat during tha sama pariod advanced from eight to thirty-fiva millions of bushels. The valua of tha wheat crop aloua, for 1867, was more than half that of all tha gold taken out in tha Stats; whila the total value of tbe agricnltural products exported that year reached an aggragata of seventeen million of dollars—mada np from some twanty or thirty different articles, for which the Stata was, a few years before, dependent upon othar countries for har own supply.

The highest price paid for wheat, subsequent to tha era of high prices in '49 and '50 was in 1858, when it reached $6.75 per hundred pounds. Tha lowest price was in November, 1860, when it touchad $1 par cental.

The yield of barley has inoraased from 9,000 hushals in 1862 to npwards of 11,000,000 in 1874. Wool from savan to forty million pounds, and wina from $28,000 in valua in 1862 to over ona milliou in 1873.

Tha number of neat cattle in California in 1850 was estimated at 300,000—a graat reduction having taken place partly through neglect snd pillaga, but mora largely parhaps from the suddan increasa of demaud for beef during tha two previous years. In 1856 thair number had again increased to over ona million.

The present value of the live stock in the State may be sat down at $40,000,000; the valua of agricultural implements, $6,000,000, and of farms and improvements at $160,000,000—making a grand total, exclusiva of the valua of products on hand, of $206,000,000. Tha number of peopla actually engaged in agricultural operatious must be something over 50,000—aside from the women and children depandent upon tham. Tho numbar of grist mills required to furnish the paople of tha Stata with flour and to meat tha demand of our axport trada for that articla is 152.

Tha wool product of the Stata is fast approaching in importance to that of wheat. Duriog the most palmy days of the missions thair flocks navar exceedad au aggregate of 1,000,000. They now exceed 6,000,000. The estimata of tha wool clip for last year was set down at 34,000,000 pounds—about oua-half of tha prodnct of all the other States in the Union five years ago.

Next in value to wool aa an article of export is our product of wina. California has already bacome one of the wine producing countrias of the world, and bids fair in a short time to hold the same relation to America as a wina making Stata, that Frsnce holds to Europa. This industry first bsgan to figura prominsntly in tha axport trada in 1868, during which ysar about 10,000 gallons were sent abroad. Tha amount shipped in 1874 was 1,000,000 gallons. Tha product of this year is astimated at 9,000,000 of gallons, valued at $4,000,000.

But fruit is, perhaps, after all, tha particulsr article of our agricultural products in which Californians most delight, and in regard to which they sntartain the grastest pride. Tha racent rapid iucreasa in tha Esstsrn demsnd for this articla spaaks mors aloquently than words can axpress the estimatiou in which the products of our orchards and vinayards are regarded abrosd. The first fruits and vinas, as already sean, wera introducad hare by tha aarly missionaries; but they paid very little attention to quality or variety.

Tha first trees introduced iuto Califoruia, ontsida of the missions, wsrs received from Oregon in the spring of 1853, and were set out in a nursary, comprising forty acres, in San Jose, by Mr. John Lewelling, now of St. Helena, in connectiou with Mr. E. L. Beard. From this nursery were derived ths millions of trees with which the gardens and orchards of Califoruia have sinca been filled. Tha parsnts of thasa trees wera taken ovsrland from the Mississippi valley to Oregon in 1848. Thsy wsrs sat out in a wagon body filled with a prapared compost, cut back to within thres inchss of tha earth, snd in that condition transported across the plains. They commsnced to grow as soon as they left tha Missouri rivar, and continued to thrive until their arrival in Oregon, whera thsy wera trausferred to a nursary.

Tha missiou Fathsrs came hither with but ona variaty of the grape. Tha number introduced sinca 1849 cannot be less than ons hundred. Tha product of grean fruit in 1874, aside from grapes, has been set down at abont fiva million pounds, and dried fruit about one million. Tha incrsase in gresu fruit over ths pravious year was abont 25 per cent.; and that of drisd fruit mora than fifteen hundred per cent. And yat the fruit business of the State is still in ita infancy.

Tha culture of the sugar beet hera has now fairly passed its experimental seasen, and may be sat down as an astablished iudustry, capabla of indefinite expansiou. I hava been informed within a few days, by partiss intsrested in this industry, that sugar is now being manufactured iu Sacramento at a cost which will parmit of its shipment to New York at a handsoma profit. This fact, if such it is, is ona of the most important connected with the agricultural industry of the State. It looks to possibilities which can scarcely ba estimated—exceeding in valua and importance even those of our great ceraal staple. There are several other promising interests connected with agriculture to which allusion might be made did time permit.

In 1850 it was astimatsd that there were not more than 15,000 acres of land under cultivation in tha State; six years latar tha amount had increasad to 500,000; while to-day—twenty-four years later—wa hava not less than 2,700,000 acras under cultivation, and nearly half as much more enclosed for othsr purposes.

Your spaaker, who is not himself a practical farmer, may ba pardoned in this connsction, in claming for California agriculturists as a class, a decided superiority in many respects over their brethren in othar portions of the world. As a general thing brokeu down psopla do not come to California—they lack tha energy for such a trip. Our people hero are mostly from the uccessful ranks. They come hera because they think they will have a batter opportunity to employ thair ganius than can be found among the slow going people of older communities. Our farmers may not be ovar industrious in the way of manual labor, for our genial climate, fialds comparatively weedless, and a soil easily cultivated are conditions which greatly lighten the necessity for toil. They may not ba as aconomical in their habits as their brethran in most other countries, for cheap lands, high prices and oomfortable incomes ara not calculated to angender picayuish habits of economy. But if our farmers make light work with their hands in the field, they keep thair brains husy, wherever they may ba. This fact is axamplified in many ways maka light work with their hands in tha field, they keep thair brains busy, whorever they may be. This fact is examplified in many ways, and notably in the extraordinary activity, novalty and practicability which is manifested in tha way of agricultural improvemants and inventions in California. Evary yoar of our history since 1862 has added one or more new and important labor saving machines to the list of agricultural improvements, the invention of some practical California farmer. Nearly every agricultural machiue which has been introduced hara from the East, has been mora or less modified and improved, and such improvements hava ganerally bean adopted at tha East. Most notahly has this haen tha case with tha plow, the header and tha threshar. Tha plow haa bacoma almost au entire naw instrument in the hands of California iuventors, aud so has tha headar. Tha gang plow, first introduced on the prairias of Illinois, was a bungling, impracticable instrument, which was discarded thera and sent to California aa to an out of tha way placa, whare it might ba possibly made to do some sarvica. Our inventors took hold of it, romodeled and so improved it, that it is now an indiapensable instrumant on avary farm, and to-day the California gang plow is as popular in the Mississippi valley as on the Pacific coast.

Notwithstandiug the favorable conditions of climate and soil, thoss who ambarksd in agricultural operstions at an sarly day after the discovery of gold hers, had to work thair way upwards and onwards against many obstacles and not a few powerful combinations. Agriculture was at first rsgarded by tha mssses as entirely out of plaoe in California—our winters wera too wet, our summars too dry, labor too high, and tha permanence of our population quite too uncartain. Cspitalists gave tha businass a cold shouldsr, and ths nswspapers gave it very little ancouragament.

Another grsat drawback to success in this business was tha lack of knowladga in ragard to the seasons. Everything hore in ths practica of agricultura was antiraly differsnt from whst had been learned alsewhera. We had floods and drouths iu tha summsr, which seamed to alternate with the most perplexing uncartainty.

Ths establishmsnt of sn Agriculturs] Collega in connection with this Univarsity ie ons of tha crowniug acts in tha history of California agricultura. For this ws ara chiefly indebted to ths liberality of tha Gsneral Government. Let ma congratulate you all as studants, and particularly you who havs chosen tha usefnl and ennobling study of sgrionlturs as your specialty, upon ths privileges which you here enjoy. Your opportunities ara rara—use them wsll to the and that yon may profit personally, and that au influanca msy go out from thess walls such ss will eventually bnild up, hera in California, a systsm and practice of agricultura which shall be ths model systsm of the Union.

Ons of the most hopsful and significant signs which we observe in connaction with tha history of sgriculture iu Califórnia, is the msrked absance of what we see, almost nnivarsally in tha agriculturs] communitiss of the East—ths tendancy of tha batter portion of their populatiou to desert tha farm and seak for whst they deem mora congenial employmsnt in cities and towns. Whils hera we witnass tha manifestation of a greater wisdom—tha bettsr portion of town and city rasidents seeking for opportunitias to enter upon ths mora healthy, tha mors ennobliug, and, with us, tha more profitabla avocation of agricultura.

The history of agricultura in California is without a parallel. This industry, lika the Stata itself, has spruug np almost full grown at its birth. During its first dacade, from 1850 to 1860 it increased mora than nina-fold; and from 1860, to 1870 its increasa was fully 150 per cent. Since that tima it has steadily advanced, with a prospact in the future uevar more promising. Califoruia has already becoma tha largast wheat growing State in the Union, and is second in the prodnctiou of fruit. The land is teeming with pleuteousness of every product both vegatahle and mineral—bonanzas in tha mouutains and bonanzas iu the valleys. In no State doss the grain grow higher or stouter; the reapsr's haud is nowhere fuller; nowhera does tho soil produoe mora hushels to tha acre, mora stalks to tha seed or mora kernels to tha head,

Our flocks and hsrds are on every hill aud in every vallay; our orchards and vinayards ara beuding baneath the heaviest loads of the richest fruits. The wealth and riches of the tropics are at our doors, and our fields and gardens abound with avery vegetabla product which the heart can desire. Hare we have no winter to linger in the lap of spring, or eat up the profits of summer. Six months of unbrokan sunshins are given to us in which to secura the crops with which a winter of verusl softness has clothed our fields. If we sow, we ara sura to roap, and as oftan as any way wa reap without sowing at all. Labor here brings no stiffened limbs, no premature old age. No othor land benaath tha blue vault of heaven exhibits such proofs of God's special favor to man, as is seen in this, onr chosan California home.

How an Amerioan Lady Obtained a Medioal Diploma in a German University.—A few years ago an American lady, whila studying medicine abroad, having bean refused admittance to a course of medical lectures in one of tha most noted universities in Germauy, detarmined to put on male costnma and pass harself off for a young man. One day an American Consul was summoned to a hotel to see a lady from tho United States. As thara was no reception room in tha hotel, he was showu up to the room indicated in the note he had received hy tha servant. Ha looked in vain for the lady, but saw what ha supposed was a young man sitting on a trunk. Ha was soon undaceived. Tha boy said he was simply in disguise, and set forth at length tho reasons for such extraordinary action. She said she was resolved to attend that course of madical lactures, and had called on tha Consul to giva her real uamo and place of rasidonce in tha United Statea, so that in casa of tronbla she could appeal to him for protection. Tha position of tbe Con ul was a noval ona, bnt he finally consantad to taka tha lady's statamant, and promised to keap tha sacret inviolate, unless she ahould be discovared. This did not happen. The disguisa answered its purpose; the lady remained at tha institution a year, passad through the course with honor, and is doubtless now applying tha knowledge gained in her practice somawhere in the United Stataa.—*Cincinnati Commercial.*

The Sun Engine.—John Ericsson, the celabrated American engineer, is still busy with his study of the sun as a direct source of power. He told Professor Langley, who not long since visitad him, that he had not laft hia house for five years, and did not meau to during the rest of his days.

Useful Information.

Revival of Canal Transportation.

The era of canels seems likely to revive. Recently, in his ahle and statesmanlike address at the Rockford fair, Ex-Senator Doolittle foreshadowed this event, pointing out their radical distinction from railroads in the fact of their being open to everyhody's vehicle as well as everybody's goods; they cannot be monopolized. The day is not distant when Chicago will he at the head of both river and lake navigatioa, nnless strangely procrastinating. In a ssuse, too, Chicago might bring horself he the commercial month of the Mississippi. Nay, is there anything stupeadous in a oaual scrose the Stato of Michigan to the head of Lake Erie?

Ohio grew from her canals. But railroads there, as elsewhere, completely eclipsed their valne, even to the extent of their total disuse. Recently a movemeat wae set on foot to repair this neglect. The board of publio works of that State hegan,in Cleveland, a fortnight ago, an official eurvey of the Ohio and Erie canal throughout, from the lake to the Ohio river. Hon. George W. Manypenny, who forty years ago in his yonth was active end zealous in promoting that work, is now, in the capacity of superintendent of pnhlic works of Ohio, at the head of the survey, with a competent engineer. The whole body set out ia carriagee, and will follow the tow path throngh, consuming tha whole aatumn, carefully inspecting the overgrown and long idle ditch, once the just pride of the State. Similar movemeats are in contemplation, we understand, in Indiena and elsewhere. Let it be remembered that of possibla canals, not a mile in a hundred has yet been dug in the country.

Cinders in Mortar.—These are often used in the mortar for plastering when the sand is not snfficiently sharp, and answer well. The material oen also he used for brickwork, when ground fine and screened. They are nndoubtedly a valnable material, if subjected to proper treatment. One essential to their use in mortar is a grinding or mortar mill; indeed, this is a valuable adjunct in the mannfaotnre of aay kind of mortar, as it insures a degree of thorough incorporation of materials that oannot be arrived at hy hand labor. It is a mistake to adopt cinders in lieu of sand—they shonld he allied with sand, and so assiet in the main composition of the mortar. Care ehould be takea that the sand is clean and free from argillaceons matter, and that the lime should he fresh, pure and strong, caloined from a class of limestone, highly orystalline in its character, or in other words such as a plasterer would call "fat lime." With these appliances and materials at hand a good mortar may be made of one-fourth lime, one-fourth sand and two-fourtbs ash or ciaders.

Use of Talc in Steam Boilers.—MM. Vigier and Aragon recommead the nse of talc as a preventative of scale. The Lyons and Mediterraneen reilway is stated to employ the method extensively, and with excellent results. The quantity of talo placed in the hoiler at once ie about one-tenth of the weight of the solid deposit produced hy two snccessive washings of the boiler. Not only is the formation prevented, hut that already formed hecomes gradually detached and carried away. This is a novel and interesting application of a cheap and abundant mineral, which has meny curious properties, but hitherto has not heen tnrned to much industrial accoaat.—*Moniteur Industriel.*

A New Mode of Preserving Fruit.—Fruit is kept in Ruesia by being packed in creosotized lime. The lime is slacked in water in which a little creosote hes been dissolved, and is allowed to fall to powder. The latter is spreed over the bottom of a deal hox, to ahont oae inch in thickness. A eheet of paper is laid above, aad theu the fruit. Over the fruit is another sheet of paper, then more lime, and so on till the hox is full, when a finely powdered charcoal ie packed in the corners, and the lid tightly olosed. Fruit thus encloeed will, it is said, remain good for a yeer.

Dry Rot in Floors.—Oil cloths have a very injurious effect upon floore, under most conditions, producing dry rot in a very short time. This is no donht due to the want of free ventilation to the floor; the joists and flooring are so imhedded and covered that no air can reach them, but the greatest evil is found to he the kamptulicon floor cloth, cemented down at the edges. All impervious floor cloths accelerate decay in the floor, and are better avoided. With such ooveringe the floors ehould be well ventilated by air openings betwesa the joists.

A substitute for ink has been devieed in Berlin, which consists of pointe, like the leads of ordinary pencils, that can be fitted to holders. The writing at first very mnch resembles lead pencil marks, but moistened immediately essumes a violet tint, and then adheres to the peper like ink. As many ae six good copies oen he teken from it by means of an ordinary copying press.

The railways in India seem to run to hridgee. A single English firm has built no lees than 16,000 iron hridges for the Bombay, Baroda aad Central India, and Indiaa railways. The last oae constructed and eent out is to have an entire length of 9,068 feet.

A New Copying Ink.—Manager Maynaid, of the Western Union telegraph, has beea experimenting for soms time on a new style of ink, his own invention, which will copy wlthout blurring, and which will not blur on the original (after drying) from the tonch of the hend before it had been copied. He has so far succeeded that the company here intend adopting it shortly. In color it is a nice shade of violot, and flowe from the pen freely. It seems to dry into the paper quickly, hut at the same time is easily bronght out npon the impression sheet, the finest hair mark coming out plain, the heaviest shaded letter copying without a blur, and as many as five copies being made from one writing, *not at one impression*, hnt in five successive onee. It is certainly a greet improvement over the ink now used, and it is claimed freezing will not destroy its properties. It has been redneed with water nearly ono-half and still retained ite copying qualities. It ie equally good for ordinary writing, as there is nothing in it that will glue or stick the pagee of written matter together should the procantion to use the blotter freely be neglected, as is the case with other copying inks. It has also been usod on the tapes of Gray's printer and Sholee & Glidden's type writors as successfnlly as on the Western Union office blanks.—*Telegrapher.*

Gutta Percha and India Rubber.—A Boston merchant, who imports nearly all the gutta percha which enters the United States, writes to the *Scientific American* to say that "the only region of prodnction thus far discovered is the East India islands in the immediate vicinity of Singapore." The principal nse made of gutta percha ie for insulating telegraph cablee and for cementing. India rubber is collected in localities all aronnd the globe hetween the tropics. The best comes from the banks of the Amazon river. Brazil produoee annually about 14,000,000 pounds, and the Central Americaa States, Africa and the East Indies together about 15,000,000 pounds. The consumption of india rubber ie ahont equally divided hetwcen Europe and the United States.

Chimney Shafts.—The diameter at the base should not be less then one-tenth of the hight. Batter of chimney, 0.3 in. to the foot. Thickness of brickwork, 1 brick from top to 25 ft. from ditto; 1½ hrick from 25 ft. to 50 ft. from top, increasing hy half a hrick for each 25 ft. from the top. If the inside diameter at the top exceeds 4 ft. 6 in., the top should be 1½ brick thiok. Firebrick liniag of 4½ in. thick and air space of 3 in. ie generally oarried up about oae-fifth of the total hight of the chimney.

A Step Further.—M. Bert, the French scientist, invented a procese of preserving meat hy compreseed air, and now M. Reynoso goes a step further, having accidentally discovered that meat tbus treated may afterward be exposed to the ordinary atmosphere indefinitely without decomposition.

Good Health.

The Best Physicians.

All physicians give fewer druge than formerly, and have greater faith in the curative powers of natare and good nursing. A French phyeician gavo good advice to his medioal friende.

As the celebrated physioiaa Desmoulins lay on his death-bed, he wae visited hy the most distinguished medical men of Paris, as well ae other prominent citizene of the metropolis. Great were the lamentations of all at the loes to be sustained hy the profession, in the death of one they regarded as its greatest ornament. But Desmoulins assured his hrother praotitioners he left hehind him three physioians much greater then himself. Each of the doctore, hoping his owu name would he called, inqnired anxionely who would he sufficieatly illustrious to surpess the immortal Desmoulins. With great distinctaees the dying man answered: "Their names are water, exerciee and diet. Call in the service of the first freely, of the second regularly, and of the third moderately. Follow this advice and you may be well without my aid. Living, I could do nothing without them; and dyiag, I shall not be missed, if you make friends of theee, my faithfal condjutore."

Ventilation of Clothes Closets.—Too lit tle attention is paid iu the coastruction of closets to their proper ventilation. It is not always coavenient to have a oloset door stand open, and if it were, full ventilation cannot be secured in this way. There ehould be a wiadow or an opening of some sort from the cloeet to the outer air or to a hall, so that a current of air might remove any nnpleasaat odors arising from clothing that hee heen worn, from shoes, or from anything else kept in the closet. A garment that has hung up for a length of time in a close closet is as unfit to wear, unless it has heen thorougly aired, as though the nawholeeome vapors it had absorbed were visihle to the eye. The charm of olothiag new and clean lies far more in the absence of theee vapors than many people are aware,

Avoid Rancid Butter.—All rancid fate are unwholesome. They alter the character of digestive aotion and affect health unfavorably. Strong coustitutions can bear the consequeaces of moderate rencidity without mnch apparent harm; hut infants and invalids feel its depressing effect upon digestion and health at once plainly.

Hearty Suppers.

Eating a hearty meal at the close of the day is like giving a laboring man a full day's work to do just as night sets in, although he has been toiling all day. The whole body ie fatigued when night sets in, the stomach takes its full share, aad to eat heartily at supper, and thea go to bed, is giving all the other portions and functions of the hody repose, while the stomach has thrown upoa it four or five hours to dispose of breakfast, and a still longer time for dinner. This ten or twelve hours of almost incessant work haa nearly exhausted its powers. It cannot properly digest another full meal, bnt lahors at it for long hours together like an exhausted galley slave on a newly imposed task.

The result is that, by the unnatural leugth of time tho food is kept in the stomach, and the imperfect maaner in which the exhausted organs manage it, it becomes more or less acid. This generates wind, this disteads the etomach, this presses up itself against the more yielding lungs, confining them to a largely diminished space. Henco, every hreath taken is insufficient for the wants of the system, the hlood becomee foul, black and thick, refuses to flow, and the man dies, or in delirium of fright leaps from a window to commit suicide.

Let any reader who leeds aa inactive life for the most part, try the experiment for a week of eating absolately nothing after a one or two o'clock dinner, and eee if a sounder sleep, and a vigorous appetite for breakfast and a hearty dinner, are not the pleasnrable results, to say nothing of a happy deliveranoe from that disegreeable fullness, weight, oppression, or acidity which attends overeeting. The great renovation and vivacity which a long, delicious, soothing sleep imparts hoth to mind and body will of themselves more than compensate for the certainly short aad rather dabious pleasnre of eeting a supper withno special relish for it.—*Investigator.*

Analysis of the Human Breath.

An account of some experiments made with the view to determine the organio matter of the hamaa breath in health and disease, presents some fects of a peculiarly interesting nature. The hreath of eleven healthy persone and of seveateen affectsd by different disorders was examined, the persons heiag of different soxes aud eges, and the time of day at which the breath was condeaeed varyiag. The vapor of the breath was condensed in a large glass flask surrounded by iee aad salt, at a temperature of several degrees helow zero, the fluid thus collected being analyzed for free ammonia, urea, and kindred substances, also for organic ammoaia.

Amoag the varione reeults of this examiaatoin may be mentioned the fact that, in both healtb and disease, the free ammonia varied coasiderably; the variation, however, could not be connected with the time of the day, the faeting or fall condition. Urea was sought for in fifteen instencee—three healthy persons and twelve caees of disease; but it wae only found in two oasee of kidney disease, in one case of diphtheria and a faint indication of ite preeence occurred in a female suffering from oetarrh. The quantity of ammonia ariaing from the destruction of organio matter also varied, possihly from the oxidation of alhuminous particles by the process of respiration; hut in the healthy persons there was a remarkahle uniformity ia the total qaantity of ammonia ohtained by the process.—*Investigator.*

A Disinfecting Cologne.—A correepondent of the Philadelphia *Medical Times* says: "Duriag the prevaleace of small-pox in 1871 and 1872, I hed frequently heen requested by my friends to prepere a cologne possessiag disinfecting properties. I found in preparing such an article that upon mixing hydrate of chloral and cerholic acid the disagreeable odor of the latter wae almost entirely removed, and upon adding these to spirits of lavender or ordinary oologae-water, a aot unpleasant odorous volatile solation reeulted. This, used with an atomizer, readily saturated an ordinary sized apartment with the vapor of these most valuable antisoptics."

Salicylic Acid for Burns.—There has been iu hospital for maay moatbs a oase of exteneive burn, in which different applications have been tried. Every new dressing succeeded well for a time, hut eoon it ceased to prove of advantage. The last agent that has been used, and is used at present, is selicylie acid. The effect is more heneficial than that obtained hy any of the former remedies. The method of nsiag it is to form au emulsion with olive oil, one part of the salicylio acid to sixteen parts of oil. This mixture is painted over the ulcerated surface once or twice a day. It gives rise to a slight smarting sensation when first applied, hut that soon paeees off.—*Med. Times.*

Analysis of a Human Body.—Dr. Lancaster, of London, recently analyzed a men and presented the result of his investigation, es far as possihle, in a palpable form before the audience at one of his lectures. His subject's body weighed 158.4 poande. The lecturer exhibited ou the platform 23.1 pounds of carbon, 2.2 pouuds of lime, 22.3 ounces each of sodium, iron, potassium, magaesium and silicon. He apologized for not exhibiting also 5,595 cubio feet of oxygeu, 105,900 cubic feet of hydrogen and 52 cubic feet of aitrogen.

Domestic Economy.

Fish as Food.

As a sonrce of nutriment, as a field of profitable industry, extending enormously the area of food production, admitting of vast expansion, which can ho worked at every season of the year, requiring no outlay in seed or tillage, and no artificial stimnlants to renew their harvest (for the fisherman reaps where he has not sown and gathers where he has not scattored), the fisheries deserve the consideration of all who feel how largely the comfort and well being of a people rest upoa tbat humble but solid hasis—ahundant and low priced food.

It was computed by the late Mr. Mayhew, in bis work on the "London Poor," that during the months of October and Novomher, or what is termed the costermongers' fish season, 800,000,000 herrings are disposed of in the streets of London alone, providing a cheap and wholesome meal for thousands and teus of thouaands of the humble classes of the metropolis.

The prejudice against a fish diet which was long current was hased upoa the assumption that it yielded but little nutriment. The result, however, of an analysis of various kinds has proved that they contain nearly as much alhuminons matter as the flesh of quadrupede—hence, as flesh-producing food, fish is nearly equal to beef. The herring coutains, moreover, a large qaantity of oleaginous matter in addition to its albuminous principle, hy which its nutritioue properties are considerably increased. It is evident, therefore, that fish were designed to oocupy an important place iu the sustenance of mankind, and it certainly contributes agreeably to that variety of diet by which the human frame is maintained in its highest degree of vigor and health. Nitrogen is a well known and important vital stimulant, and the proportion of nitrogen relatively to cerbon, estimated in grains, is ia flesh meat as 160 to 2,580, and in herrings 217½ to 1,435. Fish is a flesh and muscle, not a fat producing aliment, as is obvious from the appearance of our seafaring populatian, who are spare, sinewy aad strong, and free from thoee mouatains of flesh and masses of hlubber which characterize the prosperous beef-eating Englishmau, aad have from time immemorial typified the traditional John Bull. —*Blackwood.*

The Use of Rice.

Most readers think thie is something easily prepared. So it is, perhaps, but few nurses have an idea of the necessity of haviag it properly done—that is, cooking it until every grain hecomee perfectly *softened*. If the grains are not rednced to this soft stete, the rice is almost certain, when swallowed, to irritate the digestive organs, aad instead of soothing the parts and sustaiaing strength, will actually produce a diarrhœa, etc. Thie has been frequently noticed in hospitals.

When properly boiled until each particle hecomes so softened thet the *grain* cannot be detected when eaten, hut not cooked so much that the shepe of the grain is destroyed, and the mass reduced to the appearance of pasto, there are few articlee of diet for the sick which osn be mado more acceptable to tho taste of invalids than boiled rice.

Rice is iaferior in nutritious qualities to wheatea flour, and should by no means be depended on as a maia oonstituent of the dietery for infants, but we may enpply an agreeable change, especially whea the howels are in a relaxed conditioa.

It bas been a favorite food for children ever eince its first introduction, and is recommended by many of the earlieet English writers on the managsment of infants aud children. Every nurse has her own formula for the preparation of rice foods. The following is a very good one: Take two tableepoonfuls of the best rice and soak for au hour in cold water. Pour away this water and then maeerate and gently simmer the rice ia a qaart of water for two or three hours. Strain through a fiae sieve, and add warm milk, with a little loaf sugar and a few grains of salt.

Cheap Cookery.—We noticed, while visiting a large steel-making establishment recently, tbat the workmen at nooa iugeniously utilized the ingots of steel, which lay cooliag in the yerd, as cooking stoves, and eeemiugly prepared their dianers over the heated metal as easily as over a fire. The idea is a good oae, and might be adopted with advantage hy the men in all metal-working concerns. We helieve that the custom ie not common among the workmen in this country, nor in Eagland, though it owes its origin to and hes long heen practised in the tin melting establishmeats of Cornwell. It is considered qaite a civility there to offer a visitor a chop nicely broiled over a recently run ingot of tin. The big hammer block, we were told as an especial wrinkle, is the best place to fry things, es it is smooth and nsually just hot enough. Ingots are ordinarily rough and generally somewhat too warm. In wiater time, a workman oan ecoaomize considerably, and at the same time get a hot diuner, by thue utilizing the waeted heat of the metal.

Vegetables do not ordinarily form as large a part of the ordinary subsistence of an American as they should. Whether cooked aloae or jointly with the cheaper pieces of meat, in tbe form of a ragout, they will always serve as a suhetantial means of autritiou aud tend to diminish the cost of household consumptioa.

MINING AND SCIENTIFIC PRESS

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, W. B. EWER, GEO. H. STRONG JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 *week.*	1 *month.*	3 *months.*	1 *year.*
Per line.....	.25	.80	$2.00	$5.00
One-half inch.....	$1.00	3.00	7.50	24.00
One inch.....	1.50	4.00	12.00	40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the PRESS promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

San Francisco:
Saturday Morning, Nov. 20, 1875

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Improved Shingle Machinery; Thanksgiving Day, 321. Work at the Foundries; A Glorious Rain; Our Home Industries, 328. A Prospecting Trip in British Columbia; Heading and Shingle Machines, 329. Patents and Inventions, 333.

ILLUSTRATIONS.—Improved Shingle Machinery, 321. British Columbia Mining Regions; Heading and Shingle Machines, 329.

SCIENTIFIC PROGRESS.—Solar Disturbance and Rain; The Electric Light in Telegraphy; Metallurgical Furnaces; Precious Stones Artificially Produced; Solar Telegraphy, 323.

MECHANICAL PROGRESS.—Cleaning Steam Boilers; Cement Walls in Salt Water; Paper Water Buckets; Furniture Manufacture; Iron Railway Carriages; Rolling Steel Scrap; Improved Engineer's Machine, 323.

MINING SUMMARY from various counties in California and Nevada, 324-5.

USEFUL INFORMATION.—Revival of Canal Transportation; Cinders in Mortar; Use of Talc in Steam Boilers; A New Mode of Preserving Fruit; Dry Rot in Floors; A New Copying Ink; Gutta Percha and India Rubber; Chimney Shafts, 327.

GOOD HEALTH.—The Best Physicians; Ventilation of Clothes Closets; Avoid Rancid Butter; Hearty Suppers; Analysis of the Human Breath; A Disinfecting Cologne; Salicylic Acid for Burns; Analysis of a Human Body, 327.

DOMESTIC ECONOMY.—Fish as Food; The Use of Rice; Cheap Cookery, 327.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 332.

MISCELLANEOUS.—Lower California Mines; California's Financial Condition; Los Angeles Homes and Enterprises; A Mining Swindle, 322. History of California Agriculture, 326. Wet or Dry Lands?—Reclamation or Irrigation; Diaries; Reward of Persistency; Timber Lands; Air Machinery Improvements; On the Wear of Steel Rails, 330.

GENEROUS REMEMBRANCE.—For years past the editors and publishers of the PRESS have received handsome contributions of fruit from the farm of Mr. James Lick, in Santa Clara county. We say "handsome," because the fruit was not only of choice variety, but from the motive which prompted the modest donor to wish others who supply food for the mind to enjoy the fruits of his own culture. Last week our donation for this year came in the shape of three large boxes of autumn and winter pears, of several varieties, some of which were of extra size and remarkably fine flavor, and all excellent. We are among the humble many who wish that Mr. Lick may live many years to enjoy the fruits of his own culture during his long life of industry.

PROFESSOR Jenney told a reporter of the Cheyenne *Leader* that the gold-bearing belt of Harney Peak district is about fifty miles long and will average twenty miles wide. The diggings prospected are not extraordinarily rich, but will pay good wages, and are what California miners designate as poor-man's diggings, and will pay from $4 a day upward. The richest gold deposits were found in Bear Lodge district.

WORKMEN are putting in a new hearth in the blast furnace of the Oswego iron works, Oregon. Other necessary additions and repairs are also being made to the works. Within a few weeks, it is reported everything will be in readiness for resumption of operations.

PHILIP DIEDESHEIMER is on his way to this city from New York, accompanied by his bride. Mr. Deidesheimer is the distinguished mining engineer whose estimate of the extent and value of the Bonanza mines created such a profound sensation some months since.

Work at the Foundries.

Work at the different foundries and machine shops in this city, is very slack at present. A visit among them this week showed that no large orders had been received recently, and that most of them are running light. It was at first supposed that the Virginia fire would be the cause of bringing some large orders, but it has been found that the heavier parts of the machinery are uninjured, and that only small portions have to be repaired or reduplicated. From conversation with Mr. Scott, of the Union, and Mr. Fogg, of the Pacific iron works, both of whom have been at Virginia since the fire, we should suppose that the damage to the machinery was not as bad as was at first reported.

The Consolidated Virginia mill, near the shaft of that mine, was burnt, so also was the battery mill of the California mine, the pan mill of the latter being some distance away from the battery, the pulp being carried down in a flume to the pans. Enough machinery has been saved from these two mills to put the California battery mill in working order early in December. The Consolidated Virginia mill was about a year old—that of the California was perfectly new, never having been started up, but being nearly ready. Therefore, when the California mill (the battery portion of which is being repaired), is started up, the crushing capacity of the works of the "Bonanza mines" will be the same as it was before the fire.

A large proportion of the machinery of the Consolidated Virginia mill will also be available when they rebuild. It is not supposed that anything will be done about it before spring. The main injury done was in the cracking of the bed-plate and of the cylinder, which will probably have to be replaced by new ones. Most of the small parts were badly injured by being warped and bent.

The fire is described as being very hot and quick. The wood work over the mills was of course rather light, the principal heavy timbering not being over the machinery. A tremendious wind was blowing, and as the planks fired they were blown off, and only very light burning material fell on the machinery. This is the reason why no more damage was done to the heavy portions.

The Ophir hoisting works, which were destroyed, have been replaced by other machinery. The Risdon iron works had just completed machinery for the new combination shaft of the Challar, Hale & Norcross and Savage. It was all ready to ship when the fire occurred. These companies turned this machinery over to the Ophir company, and it was immediately shipped and is now being put up. The Risdon works then received an order to duplicate the machinery for the original owners, and it is now well under way, considerable progress having been made already. The same works are also repairing the lighter portions of the machinery destroyed at the Ophir. This machinery was originally built at these works, and as the heavy portions were not badly injured the lighter portions only are being replaced.

It will be seen from what we have said that although extensive repairs have to be made, no complete works have been ordered to replace those injured. It is supposed that extensive pumping works will be ordered before very long for the combination shaft of the Challar, Savage and Hale & Norcross; but as yet no contracts have been made, and it is not known which foundry will get the order. These works are to be very heavy and of a permanent character. The foundries about Virginia are now all very busy repairing the injured works, and times are lively with them. In this city, however, business is now dull, after a very active summer's work.

A Glorious Rain.

If the farmers and miners ordered the weather they would probably have ordered just such as we have enjoyed during the last three weeks. It must seem queer to our neighbors of the Atlantic States to hear us talk about "enjoying" a long series of November rains; but if they could realize that these rains betoken not only good crops to the farmers, but freshen up business at once and give assurance of its continuance, they will perhaps be more inclined to believe us when we declare that we really like it. And when they go farther and consider that November is not with us as with them, the entering wedge to a long, dreary season of four or five months' duration, but is the black sheep in the flock of months, and not very black at that, they may possibly acknowledge that we know what we are about after all.

The rejoicings over the November rains are quite general in the city, but the indications of satisfaction are most perceptible about the establishments of seedsmen, the agricultural implement warehouses, etc. We would ask those who are spending their first winter in California, to note the marked difference in the greeting which winter receives here and "back there;" and also the apparent hope and confidence with which our farmers perform their work as contrasted with the solemn dread which characterizes the operation of the Eastern farmers. This is owing to the difference in climates; partly as they influence the mind and partly as they are known to affect the crops that are submitted to their influences.

There is at present unusual confidence manifested in the results of the coming agricultural year. This confidence will, of itself, produce good results. It will increase the acreage to be planted, and encourage a more thorough system of farming; and extending as it does through the banking, manufacturing and mercantile classes, it will have a tendency to release the grip on money and stimulate business generally.

The miners, too, will do their share towards the happy result, and are now rejoicing in the abundant rains which will soon set the sluice boxes running at a lively rate, and fill the huge ditches and reservoirs of the hydraulic mines.

On Thursday, when this is written, it is still raining hard, having passed a stormy night; but the getting about the city has improved by means of the storm. The ground is packed and settled and the muddy water has run off.

Mr. Tennent informs us that up to Thursday, at 8 A. M., the rain-fall in this city, for the season, was 4.85 inches; 4.63 inches of which fell in November. The rainfall for November has been very large, and still it pours.

Our Home Industries.

Boots and Shoes.

The value and importance which the above trade bears to the general industries which figure so prominently in the annals of the business career of San Francisco has time and again been subjected to criticism in local journals, and reviewed in brief by surrounding contemporaries. The incipiency of the business in this city is no doubt engendered with interest of more than common importance; but it would be a useless task to probe at the roots in order to discover the condition of growth, or recount the history, in order to become convinced that the trade, whether allied to manufacture or consisting of commercial barterings, has become separable and independent, of late years, of former sources of supply.

We are proud to express our heartfelt gratification that this state of affairs exists, and can, with fidelity to our object and purpose in fostering trade industry, or more properly, home manufacture, vouch for the energy we have infused into almost every department of business by our constant, indefatigible striving to place such reliable information, gleaned from most valuable sources, before the public, as to enable manufacturers to proceed on similar plans or adopt such means as our frequent suggestions have from time to time afforded. In this, we are assured that our efforts have not been unavailing; our epitomes of business career, success and operations, becoming the incentives to well merited trials in the numerous branches which go to make up the commercial character of the country.

As regards the boot and shoe trade of this city, the extensive local demand is sufficient to create means and ends or new sources of supply, the character of the goods depending upon accustomed usage, each locality of a State or country being partial to a certain special wear or "run" upon a certain line. The goods comprised in the stock of one of our main boot and shoe establishments aggregates hundreds and thousands of dollars in value and consists of a multitudinous description, obtained from all parts of the United States.

Our home manufacturers may be said to participate in the trade with the same degree of success, correspondingly with, the manufacturers of New England, or those in New York, Philadelphia and Baltimore, while the make of goods compares favorably with any manufactured in the country.

The house of Messrs. S. W. Rosenstock & Co., boot and shoe manufacturers and dealers, has become of equal importance as the larger houses engaged in this city. The membership, which consists, respectively, of S. W. Rosenstock and Marion Leventritt, employ exclusively "white" hands in their several departments.

The establishment is situated on the corner of Sansome and Bush streets, in this city, has a frontage of 33 feet and depth of 100 feet, four floors and basement, stone building embellished with iron front. The business offices occupy rear of first floor, which is also the principal sales department, the basement and second floor being also embraced in that category. The third and fourth floors are devoted to manufacturing departments, and occupy in addition to the space named above, also the adjoining property. Skilled superintendents are in the several departments.

Mr. S. W. Rosenstock originated the establishment about a quarter of a century ago, Messrs. Rosenstock & Price continuing operations from the time of the incipiency until 1867, when the firm was changed to Rosenstock, Price & Co., Mr. Leventritt becoming connected with the house, and still later, 1871, to S. W. Rosenstock & Co., which firm has increased in importance, their goods and those of our general houses comparing favorably with any manufactured.

Chocolate, Coffee, Spices, Etc.

As this naturally is a business having few establishments to represent its progress, it behooves us to enumerate each in detail, or at least to present a few superficial facts gleaned from casual inquiry into the nature of the operations and their value to us as one of the industrial pursuits. Among the articles mentioned, chocolate presents claims to early consideration from the fact of its manufacture and the several processes necessary to the performance of the same. Chocolate is the production of cocoa beans, which are roasted, ground and modified with sweetening substance, as sugar, the latter subjected to great heat in order to extract its natural concomitant, water. The process of its manufacture, on advanced plans and for a certain attained perfection, originated in France, where the machinery for its manufacture is alone made, and where scientific skill and ability have made it a monopoly, so to speak. The cocoa beans are the seed-kernels of cucumber-like fruit produced on the tree known botanically as *Theobroma Cacao*, and emanates generally from San Domingo, Martinique, Trinidad, Bahia, Estremadura and Surinam, which are used to a greater or less extent. The best known varieties are Caracas, Maracaibo and Guayaquil. The finest cocoa, however, is Caca de Soconsisco, which comes from a district of that name, in Mexico.

Cocoa was first introduced in Europe in 1520, and since that time its use has become fabulously immense, the use of it extending to our own country at a later date, and eventually its manufacture was deemed a necessity to supply the demand. Not alone on this account, however, but for certain specific reasons. It has been clearly proven that chocolate, when subjected to a sea voyage or allowed to become "stale" before being used, becomes deprived of its volatile *theobromin*, which is its "most distinguishing and valuable principle." Chemical analysis of the component parts of cocoa finds it to consist of water, five per cent.; starch, gum, etc., twenty-two per cent.; gluten, etc., twenty per cent.; oil (cocoa butter), fifty-one per cent.; theobromin, two per cent.

The manufacture of chocolate in this city, San Francisco, has been carried on according to the most advanced plans and mechanical and scientific appliances in the way of machinery, by Messrs. E. Gaittard & Co., proprietors of the Eureka steam coffee, chocolate and spice mills, the recipients of the highest premiums awarded by Mechanics' Institute at late fair, for superior chocolate and yeast powders. The firm personally consists of Messrs. E. Guittard and A. Birgham, gentlemen of wide experience in this direction. The first, Mr. Guittard, is a practical manufacturer, having learned the art in France, and superintends the manufacture of the chocolate in person. To Mr. Birgham, member of firm, we are indebted for the facts connected with our subject, the gentleman having bestowed much valuable attention upon the nature and origin of chocolate, and illustrated his researches in a pamphlet or catalogue, which he, in conjunction with the first named, will furnish on application, personal or by letter. From Mr. Birgham's graphic account we draw succinctly the above information, as it naturally behooves us to inquire into the origin and merit of every species of production, natural or artificial.

The Messrs. E. Guittard & Co., establishment situate at Nos. 515 and 517 Commercial street, this city, prosecute a business represented by the title of their establishment, Eureka steam coffee, chocolate and spice factory.

We will not, as intended, trace the cocoa bean through the processes of manufacture, leaving that to some future number, but will remark, in keeping with their character as progressive and enterprising practitioners of the art, that the members have introduced a prepared homœopathic cocoa for invalids, or those affected with disease where fatty substances become nauseating, as in dyspepsia, etc.; the cocoa named being subjected to processes in which there is a complete separation or extraction of the cocoa butter from the cocoa bean, this substance being the natural corollary of the bean, and determining its quality and intrinsic merit. They also manufacture extensively medicinal chocolate. This is a new feature in the manufacture of chocolates, having but lately been introduced with very great success in Paris, and having received the highest testimonials of the medical faculty. Messrs. E. Guittard & Co. have acquired the right of manufacturing these chocolates in the United States, where they have had them patented, and are already having an extensive sale for them in the Pacific States as well as east of the Rocky mountains. They manufacture four distinct medicinal chocolates, as follows: Ferruginous chocolate, being a combination of cocoa and iron; quinquina chocolate, being a combination of cocoa and quinine; purgative chocolate, being a combination of cocoa and scammony; and digestive chocolate, which is a combination of cocoa and vichy salt, the latter coming from the celebrated vichy waters. In this connection we will state also, that they are the sole manufacturers of *Cafe des Gourmands*, which is patented by this firm, and manufactured by an entirely novel process, which enables the manufacturers to retain the volatile part of the coffee, called *cafenine*, until brought out by boiling water, a quality not possessed by any other ground coffee.

They ship the goods we have named, in common with their other productions, extensively throughout the Pacific States and Territories, Mexico, Central and South America, Sandwich islands, China, Japan, etc.

THE water in the Carson river is again becoming rather low, and some of the stamps that were running a week ago are now stopped —"hung up." The snow that remains in the Sierras is well up towards the summit, and melts very slowly. Another rain is needed, or a fall of snow that will reach the valleys.

A Prospecting Trip in British Columbia.

Peter Cargotich, an old prospector and miner, well known in the mining regions of this coast, has been for the last two years and a half up at the Stickeen river mines, British Columbia, and thereabouts. Early last June he started with three white men and two Takon Indians, on quite an extended prospecting trip, traversing a good deal of ground and water in both British Columbia and Alaska. He concluded his "prospect" a few weeks since and returned to San Francisco for the winter, on the last steamer. In conversation with him the other day, he gave us a brief account of the section of country prospected and its fitness for mining. He had also made a rough map, which we have had copied and reproduce herewith, as it may be of interest to those who have had a desire to prospect in that region, to get some idea of the "lay of the land."

Mr. Cargotich left Dease creek on the 7th of June, with his party, on the way to Takou river. First went south from Dease creek about 85 miles, to Telegraph creek. The party then walked up to the head of First North fork and over by the Takon Indian trail, to the Fishery, prospecting the small streams, finding indications of gold, but nothing to pay; took canoes at the Fishery, prospecting along up to Takon Chief ranch, finding nothing to pay. Then they left the canoes and went up Middle fork. It was reported by a man called "French Joe," that there was gold up this fork, but this party found none. From head of Middle fork Mr. Cargotich went with the two Indians into the great desert, and within three days' travel of the North Takou river. His companions meantime had returned to Telegraph creek for a supply of provisions. The Indians told him that there were rich diggings at the North fork of the Takou, but being short of provisions he was obliged to turn back when within three days' travel of the place. The country was swampy and covered with small lakes, being very difficult to travel over. He then returned to the Takou Chief ranch, prospecting all along and finding some quartz and indications of placers on the streams, but nothing to pay in that country. At Takou Chief ranch the provisions which had been "cached" were found, and there he also met his companions again with a fresh supply of grub. The provisions were all packed on the back, the country being such that no animals could be used.

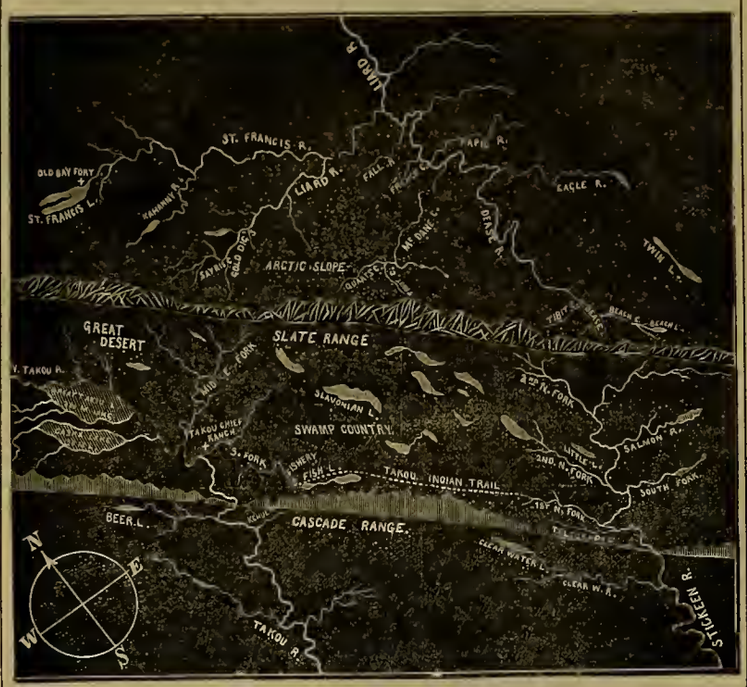
From the Takou Chief ranch the whole party went to Kchulin district, known to the Indians as a fine place for mountain sheep and other game. Mr. Cargotich had been informed as far back as 1862, by the Indians, that gold had been found there in great quantities. It took five days' travel from the ranch to this point, crossing the mountains at a time when it was blowing fiercely night and day. On the 5th of July they crossed a lake, about five miles long, on the ice. The country was very rough, covered with glaciers in every direction. On top of the summits, in some places, there was 20 feet of snow. No timber anywhere; nothing but mountains and glaciers. In the valleys there was plenty of timber and game in abundance.

In Kchulin district they found quartz containing gold and silver. It was tested in a simple way at Fort Wrangel and thought to go as high as $100 per ton. The assays made in San Francisco by Mr. Hanks, however, show a return of about $50 per ton in gold and silver, and some platinum. Some ledges of galena were found from five to twenty-five feet in width. These ledges are perhaps from twenty-five to thirty miles from the Takou river, which is navigable that far up. The country is very rough, however, being covered with glaciers, and it would be very expensive to build roads even to the river. There is no timber within sight miles of the mines. The Indians say the glaciers extend from the Takou to the Stickeen river, a distance of 165 miles. The country is very rough to travel in and no inducements were found there sufficient to make any one return.

The party then turned back by the same course to the Takou Chief ranch, then by canoe to the Fishery, then by trail back to Telegraph creek, and from there down to Fort Wrangel, on the way to Victoria to have the rock tested. At Fort Wrangel Mr. Cargotich heard of a discovery of galena ore up on the Liard river and determined to go and prospect in that direction. He accordingly returned to Dease lake to make a new start.

At Dease lake he and one partner started in a canoe to go down the Dease river, prospecting it and all its tributaries for quartz. They went up Canon creek, Cottonwood river, Eagle river, McDane's creek, Quartz creek, Rapid river, French creek, Fall river, etc. They found gold all along, but nothing to pay. At McDane's creek, Quartz creek and Trout creek many claims were being worked and paying well. At McDane's creek the miners get for wages $10 per day. The average yield is from $12 to six ounces per day to the hand, mostly bench diggings. The river is so big that it is difficult to work in the bed, being costly. The benches all contain gold, some of them being 200 feet above the bed of the creek. It is not known what the bottom of the creek contains, the water washing away the wing dams. The Discovery company has taken out a great deal of money, having about twenty men at work, paying $10 per day to the hand, the men boarding themselves. From the benches the dirt is dumped down to the bank of the river and there washed in sluices. This McDane's creek is three times as large as Dease creek, and there were about 250 men at work there and at Quartz and Trout creeks this summer, although but few wintering there. The season this summer has been short. At Quartz creek there is considerable quartz, but found nothing to pay. The quartz appears to be in bunches and pockets and not in ledges. The mining season lasts there only about three months in the year.

At French creek several companies have started work, making $5 or $6 per day, but the diggings would not pay at $10 per day in that country. Coarse gold was found up Fall river but no diggings which would pay. At the junction of Dease and Liard rivers Mr. Cargotich turned off into the Liard. At about ten miles from the mouth the galena was found, at the foot of a canon on the right hand side of



BRITISH COLUMBIA MINING REGIONS.

this river. The ledge was from four and a half to seven feet in width. A few shots were put in and the ledge was sunk upon enough to show it was not only a bunch of ore. The ore assayed is of low grade, but it would not pay there at $300 per ton. This ore run $15.50 in silver, forty-one per cent. lead and four per cent. antimony.

At Sayres' creek several men are at work, getting out about $20 per day to the hand for every day's work. The season, however, is very short. Some of the men who wintered there last winter died of scurvy. Mr. Cargotich did not go down to Sayres' creek, but he saw the discoverer, Sayris, who was going back in the spring again, as after last year's experience no one wants to winter there. Sayres thinks there will be 200 men at the creek next spring, but advises no one to come there without plenty of provisions and materials for sinking. The ground is deep, as he has sunk in places thirty-eight feet without striking bed rock. Timber is scarce, the timber being packed three miles. The gold is very coarse, pieces weighing $36 having been found. A good many men who worked at Dease creek this year will go to Sayres' creek and thereabouts in the spring. They have found quartz all around Sayres' creek, but the placer miners have paid no attention to it.

Mr. Cargotich thinks the country along the Arctic slope is a good mineral region. It is all slate formations, and the nearer they get to this range the better are the diggings. The mountains themselves have never been prospected. The country itself, however, is a very rough one. The mining season is short and the winters very long and severe. Provisions are very high, as they have to be transported so far. Mr. Cargotich thinks, however, that instead of taking provisions up to Dease creek, and from thence up the Dease river and the Liard to Sayres' creek, a distance of about 700 miles, they could be taken up the Takou river and then across the mountains to Sayres' creek, not more than 200 miles.

All the Indians are very friendly and peaceable and gave no trouble. They are good hands for packing, boating, etc., and are willing to work. In the Takou county Mr. Cargotich found coal and copper in many places, but no bar diggings. Game and fish were plenty. The greatest difficulties in traveling were the swamps, lakes, fallen timber, etc. The mosquitoes, too, were very troublesome and appeared in immense swarms almost everywhere in the summer season.

When Mr. Cargotich left Dease creek on his return trip, in October, most of the men were leaving for the winter. Perhaps 100 men will winter at the diggings. They had a pretty good season this year at the creek, but many of the claims are worked out. Thibet creek will be good for several seasons yet. The Takou and Chilcat rivers will probably be thoroughly prospected next year by the miners, and the county explored.

It will be seen that although Mr. Cargotich discovered nothing of value, he traversed a good deal of country in his prospecting trip. All of the region lies in British Columbia, although an impression prevails up there that some of it is in Alaska. The Alaska boundary follows a line thirty miles from the coast up to Mt. St. Elias, and from there runs due north. Few people care about prospecting much in such an out-of-the-way region.

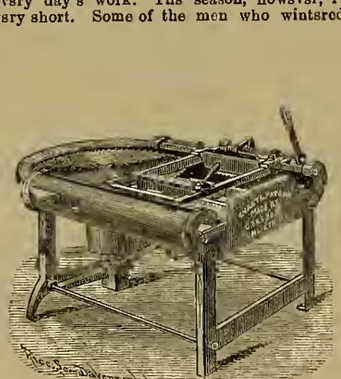


Fig. 1. Evart's Patent Single Block Hand-Feed Shingle and Heading Machine.

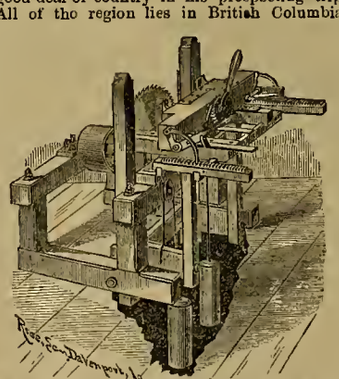

Fig. 2. Low's Patent Shingle or Barrel Head Machine.

Heading and Shingle Machines.

On our first page we illustrate two improvements in shingle machines, and on this we show two other machines, manufactured by the same makers, Messrs. C. S. & S. Burt, of Dunleith, Ill.

In Figure 1 is represented the Evarts one-block hand-feed shingle and heading machine, with the recent improvements, consisting in part of the grooved slide rods, carriage and taper works. This machine has one saw shaft, and a reciprocating carriage operated by hand. The tapering works are automatic, leaving both hands of the operator free to work the machine. The arrangement is such that the shingle can be made thicker or thinner without altering the taper, or both thickness and taper can be changed at will. Furthermore, one or more shingles can be cut from the block without change of taper, and the bolt thereby kept true and the shingles all cut with the grain of the wood; and this is done without any delay or extra labor whatever. This machine makes shingles from 16 to 24 inches in length and up to 15 inches in width. It also has a marked advantage in being adapted to the sawing of tight barrel heading, thick at the sap edge and thin at the heart. These adjustments are independent of and do not affect the saw, which is secured to the arbor by a single screw and is held in position by wide boxes, and adjusted by means of set screws at top and bottom. The saws range from 36 to 48 inches, those from 36 to 40 inches being used chiefly for shingles, and the larger sizes for sawing heading, fruit box stuff and other boards, up to 30 inches in length. The working capacity claimed for this machine, in green white pine and cypress, is about 30,000 to 40,000 shingles per day; in yellow pine, 15,000 to 18,000; and of oak heading, 8,000 to 12,000.

In Figure 2 is shown Low's patent shingle or barrel head sawing machine, also adapted to sawing short box boards, tub and pail bottoms, or any work of that class, of any thickness or length, not over thirty inches. The machine is light running and portable, and is easily attached to any kind of power. The saw is arranged in a vertical position, so that the bolt gets or carriage moves in a similar direction. The bolt is thus fed vertically down upon the saw, relieving it of the weight of the bolt, causing no friction, and leaving the shingle smooth and free from scratches. The gate is counterbalanced and has a head block to hold the bolt. The saw does not require to be removed from the machine to be set or filed, and no mechanical skill is necessary in operating it when at work. It cuts with the grain of the wood, and the shaft being horizontal no countershaft is needed. The dogs are set but once for each block. This machine is especially valuable in new countries, remote from machine shops, and has been adopted by government officials at military stations in the western territories, being easily operated and not liable to get out of order. Its capacity is 20,000 to 30,000 shingles per day in white pine or cypress, or 12,000 in yellow pine—depending on the power used and the skill of the operator.

The Steam Pump Trial.—The trial of steam pumps exhibited at the late Mechanics' Institute exhibition is now going on at the Pavilion. As we go to press (Thursday) the trial is still going on and will continue during the week. Only four entries have been made. These are the "Knowles" pump, entered by A. L. Fish & Co., the "Blake" pump, entered by H. P. Gregory & Co., the "Hooker" pump, from W. T. Garratt, who owns the patent for this coast, and the "San Francisco" pump of Wilcox & Co. While the trial is in progress no information as to relative merit can be given by the committee, but as soon as the report is made we will publish a full account of the test with such indicator cards as we can obtain. The trial is regarded with a great deal of interest in mechanical circles.

The office of the Consolidated Reforma lead and silver mining company, corner of Clay street and Montgomery, was visited on Thursday night by thieves, who were probably led on by a report that the bullion which the company was to receive from the Kohler smelting works was to be deposited at that office for exhibition. Fortunately the precious metal had not been delivered.

Rich Strike.—The *Reese River Reveille* says John Frost, superintendent of the mines of the Manhattan company, brought to that office recently a chunk of ore from the new strike at 500-ft. level of the Allsopp mine. The ore is coated with stephanite, and permeated with sulphurets, and assays $3,000 per ton. The ledge from which the specimen was taken has an average width of three feet.

Matthew Polson, an amalgamator at the Devil's Gate mill, Silver City, while at work on the 14th inst., was caught by a revolving shaft and thrown against a post. His skull was so badly fractured that there is no hope of his recovery.

The Handy-Leopard mining suit has been compromised by the payment of $40,000 by the Leopard company, $10,000 payable December 10th, and the balance in thirty-day payments of $10,000 each.

Last week's wash-up of gold dust on Lightning creek, Caribou, was as follows: Van Winkle, 670 ounces; Vulcan, 206 ounces; Victoria, 150 ounces; Castello, 36 ounces. Total, 1,062 ounces.

The citizens of Santa Clara have raised nearly $40,000 for the Alviso narrow-gauge railroad. Fifty thousand dollars is the sum required.

The El Dorado County mining ditch is to be completed within fifteen days.

The Virginia fire department lost $19,030 by the late conflagration.

A peat fuel company has been organized at San Jose.

Wet or Dry Lands? — Reclamation or Irrigation?

[From Pacific Rural Press.]

MESSRS. EDITORS:—Our State is now receiving a steady increase in population, which most likely will be a noticeable feature unti our best psrts are as thickly popnlated as the hetter parts of the Eastern States. The greater proportion of those now daily arriving among us are those who come intending to make permanent settlement, and it is a question of some importance to those who intend making agriculture a pursuit, to know where they shall most properly locate. If they shall select an ordinary npland farm, or one subject to irrigation, or a natnrally wet land, which may be reclaimed from overflow.

The ordinary upland farm, unless situsted in a very nnfavorable locality, if summer fallowed and properly looked after, will retnrn a orop; hut in summer fallowing one-half of the land may he said to be lying idle, the whole lsnd heing cropped only once in two years.

Irrigated land is necessarily expensive. The average expense of bringing weter is considerable, without inclnding the outlay necessary to put lsnd in a proper condition to receive it. Those trscts whioh lie flat and level csn undoubtedly be irrigated at much less expense than those tracts which are irregular, bnt it is safe to say thst the average expense of hringing water and conveying it properly on larger tracts of land, and of leveling off lands which are not naturally level, will cost from eight to fifteen dollars on the original cost of the land. Upon the ordinary farmiug uplaud of the State, it may be doubted if the yield of wheat will average ten bushels to the acre. Upon land properly irrigated we may snppose the average yield to he thirty hushels to the acre.

It has not been until within a few years that public attention has been drawn in this State to the plan of reclsimiug our swsmp and overflowed lands, as illustrated in Sherman, Grand, Staten and other islands, snd although some tracts have been cheaply and inadequately reclaimed, for speculative purposes, and although our hest reclaimed tracts may not be up to the standard which will be found necessary to stand the test of years, still we may say that the results of cultivating such lands prove conclusively that they will be found here, as they have been found in other oountries, to be by far the most prodnctive and valuahle of any. We refer particularly to that tract of freeh water tide land, comprising some 300,000 acres, situated quite at our door, at the delta of onr two largest rivers, the Sacramento and the San Joaquin.

Thie tract bears hut a small proportion to the halance of farming land in the State, yet from ite wonderful productiveness will be found of great importance in the future, when our popnlation will be from ten to twenty timee larger thau at present; for, having a practical immunity from drouths, aud heing of an inexhaustable character, will eupply not only the most luscious fruits, and in this respect vie with the uplands, hut give ne what the uplands may not he able to give—all our vegetahles with varied profnseness.

These are emphatically dairy lands, and are especially adapted for making butter and cheese, for fine stock, for fattening mutton, and for growing enormoue crops of sweet and Irish potatoee, turnips, beets, cahhages, pumpkins, and, in fact, all vegetables. The yields that have already been obtained on these lands, of potatoes, beane and onions, would seem fahulous, if repeated evidence was not so plentiful; $400 and $500 worth of onions, and $200 and $300 worth of potatoes and heaus to the acre are by no means uncommon; and in alfalfe, a yield of from eix to eight tons to the acre is of common occnrrence. Farmers are now cutting on those lande their fourth crop of alfalfs, and from four to five tons of the choicest timothy hsy have heen cut this year to the acre on Staten island, upon land that the seed was sown last yesr after the grain crop was removed, and upon land which the year before was unreclaimed and covered only hy the useless tule. These lands, unlike salt marshes, are suitable for hreaking up and cultivating as soon as reclaimed. The tule is hurnt off clean after the hcavy winter frosts, leaving the ground ready for the plow.

It is estimated that the yield this year in grain from 25,000 acres of this land approximated in value to $1,000,000, aud a very much larger tract will he brought nnder cultivation next year. A considerable tract, comprising 20,000 acres on Roherts' island, commencing a few milee from Stockton on the San Joaquin river, is heing enclosed and will he completed hy J. P. Whitney this year. This is but a portion of the island, which comprises in all 60,000 acres, the halance of which is to be enclosed next year. Thie is the largest island among the freeh water tide lands, and is of the choicest description, heing much firmer in its hanks and general character than the lower peaty lande of the Saoramento and lower San Joaquin; and the levee which is being coustructed upon the part now being completed, is hnilt entirely upon high, firm banks, aud is wholly of solid esrth matter, and more suhstantial in character than any leveo which has yet heen constructed. This land is wholly open to lease upon five ycare' time for a percentage of crops, upon which the owner is conetructing substantial huildings upon raised mounds, upon the levee line, which is supposed to be above the highest floods which the State has ever known.

Msy not these lands, slthough they may occasionally he overflowed, present inducements to the farmer superior to those offering upon the nplands, when considering the immense yields they give, and the great sdvantsges they present to the farmer in the msrketing of his orops?

Freight from any of the reclaimed tracts lying upon the San Joaqnin or Sacramento rivers to Ssn Francisco this year is, on grain, one dollsr per ton, with open navigation, whioh can never be controlled by any monopoly. The freight on grain from a distance of 160 miles from San Francisco hy railroad will approximate five dollars per ton, giving alone in this difference, the yield being equal, a fair profit to the farmer.

While on upland, without irrigation, a year of drouth may occasion an irretrievahle loss, and the land be of no valne nntil another year, it does not follow that an nnusual flood, occasioning an overflow of reclaimed land, will prevent the lend from yielding a good crop the same year; for our extreme floods, which come between the fifteenth of December and the middle of January, occur at a period when on tule lands the ground may he left unsown, and the water heing withdrawn hy the natural fall fifty or sixty days after, the land may he sown with a certsinty of crop; for those lands can he sown even as late as June without risk, and after any such break in levees, ample season is gained for repairs, without expectation of a corresponding rise the following year.

A tendency is apparent toward the building of stronger levees than have heretofore been hnilt, and a general improving of those previously built is taking place. Those levees situated on the lower peaty islands, aro many of them quite faulty in construction and will need much attention hefore they can he depended upon. They can be made secure, thongh involving considerahle expense; hnt the greater proportion of the fresh water tide lands can be securely reclsimed sgainst any prohable flood with only a moderate expenditure per acre.

Diaries.

Having for many yesrs kept a diary, and having found it useful in more ways than one, we are induced to recommend the practice to those who have never tried it. Its use as a remembrancer is ohvious. A good memory is not everyhody's property, hut a diary, which is often an efficient euhstitute, is within the reach of all, and if regularly written upon each evening or morning demands hut little time or trouble. The entry in a diary is authoritative, where a mere recollection might he disputed; and we helieve it is admitted as evidence in lsw, as we sometimes read of csses in which an appeal is made to its pages. When some years have passed, with the changes which time never fails to hring, there is a pecnliar pleasure in looking over the leaves of an old diary, recalling soenes and incidents that had passed from the memory, but spring into heing as we glance over the record. However slender the outline, it serves to recall the events, and memory finds little difficulty in filling up the sketch. It may he, indeed, that there is something end in many of these resuscitations; hut it ie undoubtedly true that there is a pleasure in sadness where the canse is remote, where the degree is slight, and where it can be dismieed from the mind if desired. But, hesides heing a record of events useful for reference and interesting to look hack upon, we have often thought that one henefit of keeping a diary is the influence it exercises over one's daily doings. If it faithfully records, as it should, whatever we do, it is sometimes a salutatory check upon our actions to remember that they must be set down that evening in hlack and white; and the sense of waste of time is rarely stronger than when, pen in hand, we can recall nothing worthy of record among the occupstions of the day. There is a feeling akin to that of the emperor of old, when he exclaimed, "I have lost a day." It impresses one with want of results when the doings of many houre will not fill a few lines, while it is a real source of satisfaction when we note the successful accomplishment of some useful ohject, or some worthy project pushed ou nearer to its end.

REWARD OF PERSISTENCY.—David Evans, well known in thie county, has for the past ten years heen digging around in the hille, sometimes with hopes elated at the prospect of sndden affluence, and more often depressed hy unseen circumstances to the depth of poverty and deepair, yet amid all his trials and tribulations never losing eight of the fact that "it was there," and patient work would some day receive its reward. The North Slope lode, cut in the Evans tnnnel on Hoosier mountain, a vein of some twelve feet in width with two feet of pay rock, some of which assaye from two to three thousaud ounces silver per ton, with a good showing of gold, has been sold by Mr. Evans to a Cincinnati company for good figures in cash; and Mr. Skinner and E. E. Hartwell have taken possession for the company, and will at once commence business.—*Boulder, (Col.) News.*

COVERING COTTON WITH SILK.—A method of covering cotton with silk has heen devised. The silk is dissolved in hydrochloric acid, or an ammoniacal solution of copper or nickel. Water is addod until the solution begins to cloud, when the cotton, previously mordanted, is immersed in it for a few minutes. When taken out it will he found to be plated with silk.

TIMBER LANDS.—Associated Press dispatches from Washington say: Commissioner Burdett, of the General Land Office, will, in his forthcoming report, strongly recommend that all timber lands offered by the Government he appraised and thrown open to purchasers at not less than their apprsised value. He is of opinion that unless they are thus placed under private guardisnship the fine forests of the country will soon be wantonly exhausted by lumher companies and speculators, who are now stripping the land of its timher under cover of dummy pre-emption entries, or without any pretence of complisnce with the law, while the Government derives no revenue from its property, and the country sustains almost irreparable damage from the sweeping denudation of large areas of its water sheds. He will also condemn the practice of extending the system of subdivision surveys over immense hodies of worthless land west of the 100th meridian, and suggest thst only such tracts be minutely snrveyed as have any attractions for settlers. He will also recommend thst provision he made for connecting land office surveys with important points established hy geological surveys of territories, and that monuments at section corners, etc., he constructed in a much more lasting manner. The recommendation of his predecessor that the pre-emption laws be aholished and the homestead system made the only method of acquiring title to agricultural lands, is repeated and earnestly nrged upon the attention of Congress.

AIR MACHINERY IMPROVEMENTS.—The Gold Hill *News* says: A new and valnable improvement in the arrangement of the air machinery of the Bullion mine has resulted in not only a oomplete success, hut promises, if introduced, which we have no douht it will be, a complete change in the system of fnrnishing air in all the mines on the line of the Comstock. A small air engine is plsced at the 2000-foot station of the Imperial mine and a suction hox attached to the under side of the hlower with an air pipe extending upward to the 1300-foot level, at whicb point the natural draft down the perpendicular shaft fnrnishes a snpply of pure air. At that point a tunnel-shaped opening is attached to receive the downward current of air which is drawn hy the suction to the blower at the 2000-foot station, and then driven directly into the face of the drifts. This use of the natural forces combined with the additional suction power, naturally creates a saving of the power necessary to force a snpply of air through the pipes 2,000 feet. The new arrangement of the hlower works with the utmost perfection, and is fast producing a great change in the progrese of the work on the lower levels. The 1700-foot level is looking more favorable, and the enlargement of the incline ie making rapid progress

ON THE WEAR OF STEEL RAILS.—A French journal in a note ou the wear of steel rails expresses the helief that "the chief advantage which results from their use, as compared with those of iron, ie that the wear caused hy friction is even, heing parallel with the length, and takes place slowly, whereas the hest iron rails deteriorate under the influence of the traffic, aud are found to be for the most part unfit for use hefore they have lost any appreciable portion of their weight by even wear." The opinion in this country is that the iron rails laminate hecanee the loads are greater per eqnare inch than the metal can bear, consequently the eurfaoe is crushed and its cohesion deetroyed. Some etatistics which have heen puhlished within a comparatively short time show that where the maximum weight per wheel was so emall that the weight per square inch did not exceed the strength of the iron to resist orushing, the life of the iron rail approached that of steel. Where the iron of the head of the rail has been made exceedingly hard, the life of the rail, even nuder a very heavy load, hae heen nearly as great as that of stoel, if not quite equal to it. The euperiority, thereforo, of the steel, aside from its greater strength, seems to be in the greater hardness of the material.

F. MANSELL & CO.,

SIGN PAINTERS,

423 PINE STREET,

(Between Montgomery and Kearny.)

Persone engaged in the following business can have their Signs Painted at contract prices, for goods or articles in which they trade, viz:

Merchant Tailors, Gents'Furnish'g G'ds,
Bootmakers, Furniture Dealers,
Hatters, Jewelers,
Hotels, Piano Fortes,
Wine Merchants, Etc., Etc.

San Francisco Cordage Company.

Established 1856.

We have just added a large amount of new machinery o the latest and most improved kind, and are again prepared to fill orders for Rope of any special lengths and sizes. Constantly on hand a large stock of Manila Rope, all sizes; Tarred Manila Rope; Hay Rope; Whale Line, etc., etc.

OF INTEREST TO

MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially *machinery for mechanical ore concentration*, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

VIRGINIA CITY SUFFERERS' RELIEF FUND.

NOTICE.—All persons who wish to contribute money to the assistance of the sufferers by the late fire in Virginia City, will please make out their checks in the name of GEO. S. DODGE, Treasurer, and leave the same at Rooms 12 or 17, Hayward's Building, California street. Those sending cash will please forward to the same name and destination.

Several solicitors have been appointed, who are provided with pass-books signed by the President, Treasurer and Secretary. The Secretary will be daily in attendance from 9 A. M. to 3 P. M.

HON. J. P. JONES, President,
GEO. S. DODGE, Treasurer.
RICHARD WHEELER, Secretary.

BUCKET-PLUNGER STEAM PUMP.

ALWAYS RELIABLE.

Sole Agents for WRIGHT'S

STEEL SHOES AND DIES

FOR QUARTZ MILLS,

Made by our improved process. After many years of patient research and experiment we have succeeded in producing STEEL SHOES AND DIES for QUARTZ MILLS, which are unequalled for *Strength, Durability and Economy.*

Die. Shoe.

Will wear three times longer than any iron Shoes.

BUILDERS AND CONTRACTORS

Of Quartz Mills, Pans, Separators, Concentrators, Jigs, Hydraulic Rock Breakers, Furnaces, Engines, Boilers and Shafting, and General Mining Machinery in all its details, and Furnishers of Mining Supplies.

All orders promptly filled.

MOREY & SPERRY,
88 Liberty street, N. Y.

Examination solicited.

EDWIN HARRINGTON & SON,

Manufacturers of ENGINE LATHES, 48 inches swing and smaller; VERTICAL BORING MACHINES, suitable for jobbing and boring Car Wheels; UPRIGHT DRILLS, 36 inches and smaller, and other Machinists' Tools.

COR. NORTH FIFTEENTH ST.
AND PENNSYLVANIA AVENUE,
Philadelphia, Pennsylvania.

STEAM ENGINES & BOILERS

From 3 to 75-horse power. Shafting, Pulleys, Hoist Gears Quartz Mills, Water Tanks, Spanish Arastras, Pumps and Pipes, Hepburn and Belden Pans, and all kinds of Machinery for sale at lowest prices by

THOS. P. H. WHITELAW,
266 Brannan street, S. F

Highest cash prices paid for all kinds of Machinery.

ROOT'S "SAFETY" BOILER

MANUFACTURED BY THE

Abendroth & Root M'f'g Co.,

BROOKLYN, N. Y.

THE ROOT WROUGHT-IRON SECTIONAL SAFETY BOILER has been improved and perfected by Eight years experience, and the sale of

Over 1,500 Boilers,

for all purposes. Is perfectly safe from Destructive Explosion, all parts easily accessible for cleaning, Utmost Durability, Highest Economy in Fuel, Reasonable Price. Working portion composed of Wrought-iron Boiler Tubes, tested to a pressure of 500 pounds per square inch. Steam from cold water in from *ten* to *twenty* minutes.

We refer to the following parties, among others, who are using the Root Safety Boilers:

H. F. Williams.....San Francisco, Cal
Humphrey & Mock.....Millerton, Cal.
Parko & Bowie.....Virginia City, Nevada.
Chollar-Potosi Mining Co.....Virginia City, Nevada.
Union Mill & Mining Co.....Gold Hill, Nevada.
Belcher Silver Mining Co.....Gold Hill, Nevada.
Imperial Mining Co. (170 h-p)....Gold Hilt, Nevada.
J. B. Montgomery.....Portland, Oregon.

24v26-tf

Mining Affairs on the Comstock.

The people of Virginia City are hard at work rebnilding and repsiring, and in spite of snow and wind seem to keep right st it in an indomitable manner. We give some account in another part of this issue of the damage done to the mining machinery and how it is being replaced. Of the mines themselves, the condition in whioh the lower levels will be found when clesred of wster is now an item of interest to a good many people. It is probable, however, thst a large deposit of mud npon the floors of the levels will be the most nnpleasant result. The levels which are timbered are not likely to oave, as the water will only swell the timber and thns fssten it more firmly in its place. The nntimbered levels will not suffer so mnch filled witb water as they would if left to themselves, filled with hot sir.

The locsl papers speak in a hopefnl way of the ontlook for the city. The militsry patrol has been disbanded and the police again keep watch and ward. The project of constructing smple and snbstantial water works ss a protection to the oity in cass of fire is not being allowed to slnmber. A large amount has already been subscrioed to the gnarantee fund, and the leading men of the city are determined that the work sball go on. As regards workmen being wanted there the *Enterprise* says: "The principal mines in the city being crippled, there are qnite ss many ordinary workingmen here as can fiod employment; indeed, men living in the town are daily to be seen in sesrch of work. Good brick and stone masons—also skillfnl workmen of otber kinds—can find employment at good wages; but there are plenty of men here to do all the rongh work required in rebnilding the town." There will probsbly be some suffering there this winter, as it is stated by the Virginia Relief Committee that there is hardly half enough on hand—money, provisions snd all told—to keep the sick and destitnte through the winter. They estimate that the cost of properly providing for the destitute and csrrying them through the winter will not fall far short of $100,000.

In the mines the water gives no grest trouble, although reports to the contrary have been oirculated. The *Enterprise*, of the 10th, says: "The water in the Ssvage mine has been lowered about 135 feet below the 2000-foot level. In the Consolidated Virginia the flow has deoreased to about ten inches. Abont all tbat now remains to be done is to pump out the water yet remaining in the lowest levels of the several mines. The water coming in amounts to nothing—can be easily handled by one emall pump." A letter of the 14th saya that the water has decreased to withiu sixty feet of the 2200-foot level in the Savage, and on the 13th the Gould & Curry 1700-foot level wss freed of water.

The new and powerful hoieting enginee at the C. & C. shaft went into permanent operation on the 11th inet. They are direct-actiug, and work to the admiration of all the engineers and other experts who have seen them rnnning. The progress made in sinking the shaft will henceforward be fully twioe as rapid ae while the hoisting was done with tbe little donkey engine. They now take a new departure in the einking of the shaft. With the new engines a car load of dirt can be hoisted in lese tban half the time that wae formerly occupied in briuging one to the surface.

The frame of the new building in which is to be set up the engines and hoisting machinery of the Opbir was erected on tbe 12th inst. To inolose the building will be the work of bnt a few days. Work upon the machinery in the interior will be going on in the meantime, and there can be no donbt tbat the hoisting of ore will be resnmed within the time specified by Captain Cnrtie, namely, Dec. 5th.

The erection of the frame for the building which is to oover tbe new works of the Conoolidated Virginia mining oompany (says the Virginia *Enterprise* of tbe 13th inst.) wae begun yesterday. To-day the work will doubtless be completed, so far as the main building is concerned. The heaits of our people ssuk as they eaw these splendid works go down, and in proportion as they see them rise again they "take oourage." It is eome consolation to know that when the works again go into operation, and when the drift from the C. & C. shaft shall have been rnn to the vein, the big bonanzs will be made to bleed as it has never bled before. We shall then see many car-loads of silver bricks rolling down the side of the monntain. All the ehops near the Consolidated Virginia are filled with workmen, and work ie being pushed on every part of the foundations. The hoisting enginee will soon be placed in position. The boilers are all sound, and stand just as before the fire, ae the engineers before leaving tbe works turned on the pumpe and filled them full of water. Being thns water-logged, the fire did not hurt them. Since the fire tremendous galos hsve visited the city, and thrown down a number of buildings.

The Pacific wood and flume company, one of the ageuciee of the Mackey-Fair combination, hae discontinned operations for the seaeon. This throws 600 men out of employment.

A lump of pure brimetone has been sent from Winnemucca to the Centennial, weighiug 1,000 pounds.

The investigations of the Wooodville Consolidated and Niagara mining companies still progress.

Notices of Recent Patents.

Among the patents recently obtsined throngh Dewey & Co.'s Scientific Press American and Foreign Patent Agenoy, the following are worthy of mention:

Improven Dental Plugger.—T. Crossett, dentist, San Franoisco, Cal. This invention relstes to certain improvements in that class of dental plnggers in which the bit or striking point is attached at a right angle to the end of the implement, so as to be more conveniently handled and operated in the mouth. The improvement consists first in a novel arrangement for transmitting the blow of the hammer or spring shaft to the bit or plugging point; secondly, in an improved device for incressing the force of the blow when desired; and thirdly, in the method of adjnsting the position of the implement, with reference to the driving shaft of the engine or motive power to which it is attached. This implement is very convenient, not only for dentists, but pstients as well, as it enables the dentist to perform the work in the patient's month without the necessity of the latter opening his mouth wide enough to swallow the operator.

Floor Clamp.—Elijah Hiokman, Red Blnff, Cal. This is an improved device for pressiog floor boards together so as to make tight joints, and then holding the boards firmly in place while they are being nsiled to the joists. A handle or lever is nsed, to one end of which a gripping device is secured, which clamps the sides of the joists in order to get a hold, from whioh to apply the leverage. Tbis gripping device oonsists of two strong bars of metal, which cross each other like a psir of shears, and are riveted together at one point. A braoe bsr is applied, so that when the gripping jaws are fastened to the joist it will bear against the edges of the boards to be pressed. A lever bandle serves to force the bar against the edges of tbe boards. A hook-bar is applied, which serves to secure the clamp in position when working overhead, as in tbe oase of fitting ceilings. This hook-bsr hooks unto tbe eide of the joists after the clamps have been applied to it, and sustains the clamp while the workman is nailing the boards.

Alarm Fare Box.—A. J. Costis, San Jose, Cal. This is an improved till or box for collecting fares in railway cars, omnibusses, and other vehicles for carrying passengers. It consists of an arrangement allowing each passenger to drop his own fare into the box. An alarm wheel ie caused to strike by the operation of dropping the fare into the box and a register for noting and counting each fare as it is introduced. The operation of registering the nnmber of fares, sonnding the alarm and rotating a wheel with radial compartments eo as to carry the fare to a position where it is dnmped into a drawer or lock box, ie all accomplished by the movement of the ticket receiving and depositing device. The box ie compact, having only two compartments, while the ticket, wben once deposited, is beyond recovery or abstraotion.

Baling Press.—D. L. O'Connor, Covelo, Mendocino county, Cal. Thie is an improvement in baling presses, and it oonsists principally in the construction of two or more distinct compartments which are placed eide by side upon tbe same base or frame and have a common driving ehaft extending through loosely mounted actuating drums, so that by means of a snitable clutch either one or the other may be operated. The devicee for commnnicating the power to the two followere are not especially novel. By the construction of the prees the inventor is enabled to work it alternately with only one set of machinery and one gang of men, thus greatly increasing the prodnction.

Judge Whitehead, who, with a party of surveyore, has been locating a route for a railroad between Cheyenne and Montana, hae reached Bozeman, and reporte having fonnd a feasible line along the eastern base of the mountsins.

The Coos Bay gold mining company, Oregon, in damming John Mule creek, half a mile above its confluence with Rogne river, have discovered an extensive prospect of gravel that prospects three cente to the pan.

One hundred tbousand trade dollars were Thureday delivered by the Coiner to the Caehier of the Carson mint. This is the largest delivery of this coin yet made at any one time.

John Ely, a pioneer of Lincoln county and one the original locatore of the Raymond & Ely mine, has returned to Pioche after an absence of about tbree years in Frenoh Gniana.

The Fryer works at Graes Valley still continue in operation, reports to the contrary notwithstanding. Before long the whole process will be available to the public.

Joseph Williams, a blacksmith at the Ophir mine, lost an eye on Wednesday. Wbile cntting a bar of iron a large fragment struck his eye and cut into the ball.

John F. Cassel has resigned the superintendency of the Leopard mining company, and A. Plummer has been elected to fill the vacanoy.

Academy of Sciences.

The regular meetieg of the Californis Academy of Sciences was held on Wednesdsy evening last. Louis Nusbaumer, of Snncl, wss proposed for membership. The contributions to the museum comprised forty-five speoimens of minersls from Dr. Helden, a specimen of oolymbus presented by Dr. Hsrkness, two birds from the Navigator islands and a specimen of *cebidichtus* or "wolf eel," five feet long, from Puget sound, presented by Captsin James Lswson. The latter is a curious specimen of marine monster. Its head is large and its face has a semi-hnman look, while its teeth are strong and espable of msstioatiug the *crustacea* on which it probably feeds. The fish is ssid to be found occssionally in the bay by our fishermen.

Mr. J. R. Scupham msde a few remarks on tbe teredo, presenting also a specimen of wood showing a curions instance of where one of the rotifers had bored into the hole of its neighbor, the first instance in whioh such an occurrence has been noticed.

He said that the teredo was s rotifer, moving abont in the water by means of its *cilia*. When it attached itself to a piece of wood the *cilia* died. It then moved around on the surface of the wood until it found an indentation, into which it crawled and covered itself with a limy substanoe. When covered it began to bore inward and downward, never crossing a crack and hardly ever breaking into the neighboring cell of a fellow insect. It kept its hole lined with a shelly substance. Its food was of animaculæ drawn throngh its siphon, and not the wood through which it made its way. In the section of pile shown by the speaker one insect had broken throngh into tue chamber of another, contrary to precedent. Probably the neighhor was desd. From its peculiar manoer of growing the teredo must continue elongating itself or must cesse its existence.

Jndge Hastings tbought the gas furnished by the gas company was so bad that somebody shonld make an exámination of it, and suggested that Dr. Blake be sppointed to investigate the subject. Dr. Blake said tbat he waa under obligations to the gas company for means to carry on his experiments into the best methods of exterminating the phylloxera now devastating the vines of California, and he could not undertake the task. He then went on to spesk of the insect and the damage it is causing, at some length. His knowledge was principally confined to the vineyards of Sonoma county. Many young plants had been sent down to him from the vineyards there, and he had not seen one that was free from it. He thought that there was no difficulty in killing the insects, bnt no application of the extermiuator had been found strong enough to destroy the eggs. Those queetione could only be determined by experiment. Soapsuds, tsr-water, tobacco-water, creosote and carbolio acid and snlphur water had succeeded in killing the insect, but none of them had destroyed the egg. The disease had greatly in reased within a few yeare. The insect ie traveling downward, and it is well enough to know exactly how fast it travels. The agricultural jonrnals of France have just found out that the eggs of the insect are deposited at the angle formed by tho vein witb the main stalk. They come to the surface in July, and sometimes late in September. So far as the gae works were oonoerned, Dr. Blake said he had no doubt that he could get from them snbatances that would be fatal to both insects and eggs.

Dr. Kellogg auggested kerosene, but Dr. Blake thonght it might be too strong for the plants.

It was suggested that the custom followed in Germany, of kindling fires about the time of entomological courtship, would attract and destroy the males.

Dr. Behr approved the recommendation, saying that this practice was followed on the Rhine and Main, and the vineyarde in thoee regions were entirely free from the pest.

Dr. Kellogg suggested the old Aztec custom of putting plante of other odore among the vines, so that the ineect would think the vineyard not a vineyard, and fly past it.

Dr. Blake thought that the plan of fires would scarcely do, ae the insects were wingless and could not fly to it. He asked Dr. Kellogg if the *aphis* was not always wingless?

Dr. Kellogg replied that almost all speoies of them flew at that season of the year.

Judge Hastings said that the kindling of fires was forbidden by the new code.

Wrecking.—According to "The Wreck Register and Chart for 1873-74," just issued by the British Royal Life-boat Institution, it appears that there were 506 livee lost from wrecks, casualties and collieions on or near the coast of the United Kingdom. The fleet of the association, consisting of 250 life-boats, saved 713 lives from various ehipwrecks.

The Penryn granite works, in Placer county, are now turning out large quantities of polished stone for monnments, etc.

The Miners' Union of Virginia are going to rebuild their hall. It will cost between $16,000 and $18,000.

The Risdon iron worke are building a set of engines for a new steamer designed for the Humboldt route.

Patents & Inventions.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

From Official Reports for the Mining and Scientific Press, DEWEY & CO., Publishers and U. S. and Foreign Patent Agents.]

By Special Dispatch, Dated Washington, D. C., Nov. 16, 1875.

For Week Ending November 2n, 1875."

Mandrel for Broom Machines.—Henry Anderson, Vallejo, Cal.

Metallic Burial Case.—Henry M. Grsy, S. F., Cal.

Steam Boiler Furnace.—Joseph Enright, Ssn Jose, Cal.

Batter Feeder for Cake Making.—Dennis H. Lsfferty, S. F., Cal.

"The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

General News Items.

The weather in Englsnd and Frsnce during the past week has been very stormy. Almost incesssnt rains have fallen, and many psrts of both countries are flooded. Vast tracts are threatened by rising rivers.

The abandonment at sea of the Nicaraguan ship *Liguria*, eight hundred miles from Csllao, is reported. The captain and crew hnd arrived at Callao prior to the 24th ultimo.

The General Land Office has rejected the Castro survey of the Rsncho Piedra Blanca, in San Luis Obispo, and direct a new survey to be msde.

The New York Court of Appeals has dismissed Tweed's appeal in both cases, thereby refusing to reduce his bail or grsnt him a bill of psrticulars.

Don Carlos is said to have written a letter to King Alfonso. There are rumors of peace and Spsnish funds have risen in conseqnence.

The Fall River mill owners have decided to reduce the wages of their employees ten per oent. on the first Monday in December next.

The King of Italy has granted a snbsidy of 190,000 lire to aid in representing his kingdom at the Centennial.

San Francisco contributed in goods and cash the sum of $48,061 50 to the relief of the sufferers by the Virginia fire.

Hon. Jasper O'Farrell, ex-State Senator, and the first surveyor of the city of San Francisco, died on Tuesday last.

Guiborn has been buried at last and the grave filled in with Portland cement to prevent the body from being removed.

Only two lives were saved from the ill-fated *Pacific*. An investigation is to be held as to the cause of the disaster.

The President hae appointed T. C. Woodward, of Iowa, to be Exsminer-in-Chief of the Patent Office.

The epizootio in a mild form is now prevalent in this city and to some extent in the Interior.

Work on the Mare island dry dock ia at a stand-still, the appropriation having been exhausted.

The snow slides in Little Cottonwood canon, Utah, have begnn, and already this winter four lives have been lost.

All hopes of finding any of the passengers or crew of the *City of Waco* have been given up.

The Thames has risen, and done five million dollars' worth of damage by flood.

A New England conservatory of music is to be established in this city.

The brig *Maine* was capsized in the Atlantic and 13 livee lost.

San Francisco wae again visited hy an earthquake this week.

The recent Virginia fire burnt about three hundred acres.

Vice-President Wilson continues to improve.

There are now 530 guests at the Palace hotel.

Baron Rothschiln nnd party have gone to Yosemite.

The Itslian legislative bodies convened Tuesday.

Treasurer New has concluded not to resign.

A great war is predicted in Europe next year.

Professor W. Frank Stewart states in the Carson *Appeal*, ae a quietus of mieapprehension, that the great cabinet of specimens, collected by himself and State Mineralogist Whitehill for the Centennial was not destroyed by the Virginia City fire, but is safely housed, the whole ten tons of the same, in the railroad round bouses in Carson City.

The Late Awful Winter leaves behind it a frightful legacy of Coughs, Colds, and Pulmonary Inflammation. Providentially, however, an absolute and immediate cure has been provided in Hale's Honey of Horehound and Tar.

Pike's Tootbache Drops cure in one minute.

(Continued from Page 325.)

shortly, when the real width and extent of this valuable deposit will be developed and defined. The ore is of the rich sulphuret character, the same as is fonud in the big bonanza. The position of this rich strike in the Leviathan, its known extent upward to tho level above, and the character of the vein itself, shows it to be a development of importance, and decidedly enconraging to the lucky stockholders.

SUTRO TUNNEL.—Total lougth of tunnel today, 11,415 ft. Material in face of header, quartz, porphyry snd clay, considcrably mixed. Excellent progress is being made, and some of tho qnartz seams passed tbrongh give good assays. The tunnel is liable to run into an ore body at any time, as it is already nearly a thonsand feet into the broad mineral belt of the Comstock.

LEO.—The main drift has developed considerable improvement, hoth in charactor and qnality of vein matter sinco last report. The veins of quartz are widoning and show more sulphuret ore. Water does not yet interfere with the work.

ALTA.—The new hoisting works are completed, and sinking the shuft has been commenced in good earnost. Everything works with the ntmost perfection.

EUAOPA.—The main west drift is in 170 ft, the face in soft working gronud. It is confidently expected that a distance of 40 ft more will be sufficinnt to reach the ledge, when some good developments may bo confidently looked for.

CROWN POINT.—The nsual quantity of ore is being extracted and milled. The prospecting operations on the lower levels have developed no large bodios of pay ore as yet.

CALEDONIA.—Sinking the new shaft is making fair progress. The average is now abont 3¼ ft per day. There is still considerable water coming in, but not enongh to at all impede the progress of the work.

LADY WASHINOTON.—Sinking deeper is progressing finely, the pnmps easily keeping the water out, and the new machinery working to perfection.

SILVER HILL.—Sinking the main incline is making steady and favorable progress.

COSMOPOLITAN.—The prospecting work goes ahead lively, with favorable indications. Considerable good pay ore comes from the main north drift, the face of which continnes all in good pay ore.

UTAH.—The erection of the new hoisting works bnilding, and the replacing and repairing of the machinery injured by the hnrning of the old works is making steady and rapid advancement.

NORTH CONSOLIDATED VIRGINIA.—Sinking the main shaft is making fine headway, the boltom still in ledge matter, and occasionally cntting streaks and stringers of qnartz of a very enconraging character.

BELCHER.—Daily yield, 300 tons of ore. The ore breasts and stopes are looking well and yielding the usual amonnt of good milling ore.

UNION CONSOLIDATED.—Work has been again resnmed in the north drift on the 1300-ft level, the face of which is showing quite favorable for hetter ore developments than have before been enconntered in that direction.

PROSPECT.—The face of the drift shows some improvement since last report, more and richer streaks of qnartz coming in.

MINT.—The shaft is down 900 ft, the bottom in soft ledge material. The sinking is making fair progress, and there is hnt little water to tronble.

SAVAOE.—The flow of water is gradnally snbsiding, and the pnmps are rapidly draining the incline and leaving the mine in a good condition for the resnmption of work on the lower levels.

GOULD & CUARY.—The water is heing gradnally drained from the 1700-ft level, prepsratory to resnming work in that portion of the mine.

DAYTON.—Sinking the main shaft is going ahead at the rate of 2½ ft per day. It is now down 541 ft. The flow of water at the bottom is considerable, hut is easily handled by the pnmp.

SOUTH COMSTOCK.—Face of the cross-cnt still in qnartz and clay, and good advancement made toward the main ore vein at the west side of the ledge.

BEST AND BELCHER.—The water is sgain nearly extrac'ed from the 1700-ft level, so as to soon permit of a resumption of work in that portion of the mine.

PICTOU.—The face of the main tnnnel is now in a softer material, oomposed of clay, porphyry and occasional qnartz seams, with some water coming in.

MOAE SPAOE WANTED.—It is stated that the Centennial bnildings, extensive as they are shown to be, are not large enongh to accommodate the articles that are promised to be on exhibition, and that additional edifices will have to he erected for intended special displays. The area covered now is rising forty-eight acres. This is more gronnd, by ten acres, than was covered by the Vienna Exhibition. A structnre occnpying fonr acres and a half is intended for the War, Treasury, Navy, Interior, Post Office and Agricnltnral departments, and the Smithsonian Inatitnte; under the liberal appropriation of Congress for their exclnsive nses, it is expected they will be able to make a display highly creditable to the Government.—*Call.*

"The Public Lands of California."

The demand for this new work is steadily increasing, and the more widely thet its merits are becoming known, its usefulness to everyone is becoming more fully demonstreted. The map of California and Nevada alone is worth more than fifty cents, the price asked for the work, and the fact that o glance at its pages shows the leading products, population, etc., of each conuty in the State, besides a list of the surveys of United States Land, subject to the homestead and pre-emption laws of Congress; o correct copy of the laws of Congress in regard to locating and holding this land, etc., renders it of incstimable value. Orders sent to Dewey & Co., enclosing fifty cents, will meet with prompt attention, as it will be forwarded immediately, post paid.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none hnt worthy men.

THE SCIENTIFIC PRESS—This valuable paper entered upon its thirty-first semi-annnal volnme on the 3d inst. For mechanics and miners, in fact for all classes of people, we know of no paper which cortains more substantial reading matter than the SCIENTIFIC PRESS. It is published in San Francisco, by Dewey & Co., at $4 per year. No person interested in mining or other scientific pursuits shonld he without it, as it is weekly filled with invaluable scientific literature.—[Amador Dispatch.

SUBSCRIBERS are requested to examine the printed address on their papers. If mistakes occur *at any time* please report them to this office. The last figures (at the extreme right) represent the year that your subscription is paid to. Next to these the day and month is represented. For instance, your subscription being paid to July 4th, 1876, it would be represented, viz: jl 4 76; or 4j176.

PASO ROBLES, CAL., October 18th, 1875.

DEWEY & CO.—*Gents*: The letters patent for the Tire Upsetter have come to hand. For the prompt manner with which you have brought the matter to a successful issue, please accept my thanks.

Yours Respectfully, JOHN H. MENTZ.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY CUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silvar ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his speciality.

Price $2.50 coin, or $3 currency, postage free

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illnstrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO $5.

Nevada and California Processes of Silver and Gold Extraction, for general use, and especially for the Mining Public of California and Nevada, with full explanations and directions for all metallurgical operstions connected with silver and gold from a preliminary examination of the ore to the final casting of the ingot. Also, a description of the general metallurgy of silver ores. 1864.

As its title indicates, this work gives a wide range of information, applicable to all vein miners and workers in precious metals, affording hints and assistance of exceeding value to hoth the moderately informed and the most expert operator.

Price, $5 in cloth, $6 in leather—coin.

BY OTHER AUTHORS.

The Qnartz Operator's Hand-Book; by P. M. Randall. 1871. Revised and Enlarged Edition. Cioth hound, 175 pages. Price, $2.

Snlphurets: What They Are, How Concentrated, How Assayed, and How Worked; with a Chapter on the Blow-Pipe Assay of Minerals. By Wm. M. Barstow, M.D.; 1867; cioth hound, 114 pages. Printed and sold hy DEWEY & Co. Price, $1; postage free. The best written work, and most complete work on the subject trnated.

ANY OTHER BOOKS DESIRED will be furnished at the most reasonahle rates by DEWEY & Co., Mining and cientifio Press Office, S. F.

APPRECIATION ABROAD.—We copy the following from the *Mining and Monetary Gazette*, of London, Eng.: "We deemed it advisahle, as affording valuable information to our readers, to publish in recent lesnes of *The Gazette*, the fnll text of the "United States Mining Laws and Instructions, hy the Commissioner of General Land Office," taken from our talented contemporary, THE MINING AND SCIENTIFIO PRESS, of San Francisco. The documents have now been issued in a handsomeiyhound volnme hy Messrs. Dewey & Co., the pnhlishers of our transatlantic contemporary, and it will be found very usefnl to those already interested in American mines, and to others who may be tempted to embark in that enterprise in the States."

NO AGENTS are authorized to receive subscriptions for this paper at less than our advertised rates.

Mining and Other Companies.

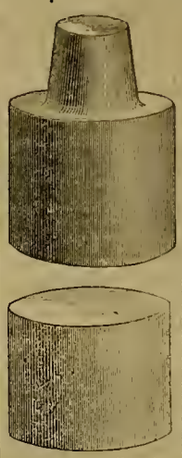
Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.



[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufactnrers havo been compelled to add largely to their works—a new gas furnace and beavier trip bammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactnred. We have consequentiy reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find thom at least 10 per cent. cbeaper than the beet iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertiee STEEL SHOES AND DIES whicb are only cast iron hardened by the addition of a composition. Tbey will not out-wear two sets of common iron, though called steel. They are very brittle and are not capablo of being tempered, flying from under tbo bammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largeet mills on the Pacific Coast, and all who have tried them pronounce them cbeaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased valuo of amalgam by absence of iron dust and chippings, and a eaving of 75 per cent. in freight. It takes 60 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

54 BUSHELS OF CORN AN HOUR.
HARRISON'S
LIGHT, VERTICAL BURR MILLS
BARBER & BACON, MILLERS AND LUMBER DEALERS, SOUTH VERNON, VT., write July 15th:
"We have been running two of your LIGHT VERTICAL CORN MILLS for the past 6 months with remarkable results, and have ground over 80,000 bushels of corn into No. 1 meal in that time, running the grist-mill nights only, as we run our saw-mill in the day time. We have often ground in the 20-inch Mill (which weighs about 500 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 24,300 lbs., or 434 bushels. To do this we have to run at a speed of 1,300 turns per minute, and use about a 20-horse power. You may refer parties to us for further information, and when we have tested your HEAVY VERTICAL MILL, we shall take great pleasure in giving the results."

American & Foreign Patent Agents.

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditionsly; Patent reissues taken ont; Assignments made and recorded in legal form; Copies of Patents and Assigmentr procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our snccess and business are constantly increasing.

The shrewdest and most experienced Inventors are fonnd among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public throngh the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assiatance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prnssia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New Sonth Wales, Queensland, Tasmania, Brazil, New Grenada, Chili, Argentine Repnblic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are reqnired in European countries, bnt the drawings and specifications shonld be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of goverment, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in trans mitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applioants for patents can rest assured that their communications and bnsiness transactions will be held strictly confidential by ns. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutnal conference of legitimate business and professional men is mutual gain. Parties in donbt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advise of importance to them from a short call at our office.

Remittances of money, made by individual inventore to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable nse.

DEWEY & CO.,

United States and Foreign Patent Agents, publishers Mining and Scientifio Press and the Pacific Rural Press, 224 Sansome St., S. F

Mining and Scientific Press.

Started in 1860, is one of the oldest weekly journals now publihed in San Francisco. It has been conduoted by its present proprietors for ten years, during which period it has been repeatedly enlarged and oonstantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi.

As a PRACTICAL MINING JOURNAL it has no rival on this Oontinent.

It is the only MEOHANIOAL, and the only SOIENTIFIO journal of the Pacific States.

Miners, Assayers, Millman, and Metallurgist in the United States shonld take it.

Pacific Coast Meohanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columns of fresh and valuable information.

Mining Engineers, Superintendents, Metallurgists, Mine Owners and Mine Workers throughont the world shonld profit by its illustrations a d descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughout the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSORIBE AT ONOE.

At a Stated Term of the Circuit Court

of the United States of America of the Ninth Judicial Circuit in and for the District of California, held at the court room in the city and county of San Francisco, on Thursday, the 30th day of September, in the year of our Lord one thousand eight hundred and seventy-five. Present—The Honorable Lorenzo Sawyer, Judge.

Nicholas Seibert, complainant, vs. Wm. T. Garratt, defendant—In equity.

DECREE.

This cause came in to be heard at the February Term, A. D. 1875, of this Court and was argued by counsel and thereupon upon consideration thereof, it was ordered, adjudged and decreed, as follows, viz: That defendant, William T. Garratt, was not the first or original inventor, or discoverer of the improvement or discovery claimed by him, in snd by thosa certain reissued letters patent of the United States, number five thousand three hundred and twenty-eight (No. 5328), for an alleged new and useful improvement in lubricators, issued to said defendant, William T. Garratt, on the 18th day of March, A. D. 1873, and is not entitled to a patent therefor, and that said reissued letters patent, number five thousand three hundred and twenty-eight (No. 5328) are declared void and the same are hereby vacated and set aside by reason of their interference with those certain letters patent of the United States, number one hnndred and eleven thousand eight hundred and eighty-one (No. 111,881) for a new and useful improvement in lubricators, issued to complainant, Nicholas Seibert, on the fourteenth (14th) day of February, A. D. 1871.

It was also further ordered, adjudged and decreed that complainant do have and recover of and from defendant his costs and expenses to be taxed herein.

(Signed) LORENZO SAWYER,
Circuit Judge.

The above decree has reference to "Seibert's Eureka Lubricator" for oiling the valves and cylinders of steam engines.

It has a glass gauge and condensing pipe, or reservoir, with a regulating feed valve, and works as follows: As the water of condensation is admitted, under the oil, just so fast the oil passes out at the top through a pipe into the steam pipe to oil the valves and cylinder.

Parties who infringe or purchase the infringed lubricators, will be held strictly responsible.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Patent Solicitors.

SAN FRANCISCO, SATURDAY, NOVEMBER 27, 1875.

VOLUME XXXI Number 22.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

AN IMPROVED CARRIAGE.—Richard L. Ogden, Kimball Manufacturing Company, San Francisco, Cal. This is an improvement on carriages which are provided with tops which it is desirable to open or close at pleasure, such as landaus, etc. The improvement consists mainly especially in a novel construction of the front so that it can be folded down forward and yet allow the top to fall back of the driver's seat. In the ordinary way of construction the front posts which support the top are hinged at their lower ends, so that they can be turned forward and carry the front part of the top with them. This top, however, must pass over the seat and lie across in front of it, which presents an awkward and unsightly appearance, as well as being inconvenient. Capt. Ogden's improvement is to split the front posts part of their length diagonally, making a joint so that the upper part of the post can be turned back as the device is forced down. The arrangement is such that the cross bar or rounded front of the vehicle falls just behind the driver's seat, making the whole look compact and neat, and remain entirely out of the way. Several carriages made for the Palace hotel have this improvement, and were exhibited at the late Mechanics' Institute fair.

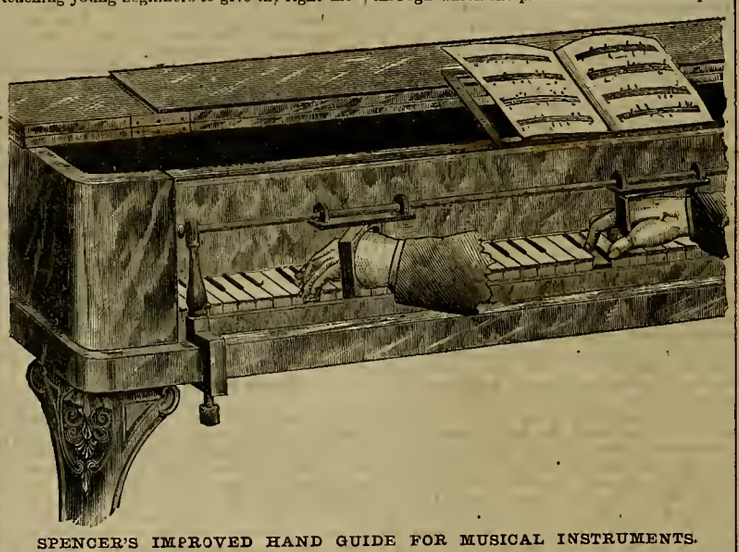
WATER-TIGHT JOINTS FOR COCKS AND FAUCETS.—Wm. C. Bussey, San Francisco. This invention relates to that class of cocks, valves and faucets in which a small shell which surrounds the water pipe must be turned to a certain point in order to connect the water passages and allow the water to escape, and which must be turned so as to disconnect the passages in order to cut off the escape of water. The invention is specially applicable to basin faucets. The improvement consists in the employment of India rubber to form the inside portion of the shell and move against the water pipe. By the use of the block of India rubber a perfectly tight joint which will not leak is provided. The frictional surface of the India rubber will be lubricated by the water so as to make it work quite easy, while there will be no wear of any consequence either on the rubber or on the pipe. The same arrangement can be applied to cocks, valves and other moving joints where it is desired to make a steam, water, or gas tight joint.

IMPROVED LIFT PUMP VALVES.—Fred. A. Ruhl, Stockton, Cal. This invention relates to certain improvements in the securing and guiding of lift pump valves, and also in a novel method of securing the pump rod to the upper valve box. In the construction of valves for lift pumps much difficulty has been experienced, first from the insecurity of the fastening of the lower part of the lower pump box, which being simply screwed on is liable to become loosened and gradually turned off by the jar and shock of pumping, so that it finally falls to the bottom of the well and is lost; or if made too light for this, it becomes so rusted to its seat that it is impossible to remove it for repairs to the valve. The valves themselves being guided by single or double spindles passing through holes in cross bars are very liable to become clogged and fixed by sand, which wedges into the guide holes. Mr. Ruhl's invention contemplates a simple and easy method of securing the parts of the box together and at the same time providing guides for the valve which will not clog.

PRINTING ROLLERS.—Wm. H. Bell, San Francisco. This invention comprises certain improvements in hand printing rollers, such as are employed for marking or labeling articles. It consists in certain novelties in construction, by which the inventor is enabled to mount different sheets of type upon the same roller and secure them firmly without nailing or other fastening. It also consists in a means of securing the printing and inking rollers in the frame, so that they are held to their places without springs, and the printing type are always brought into contact with the inking rollers by the action of putting the machine upon the surface to be marked. The device which strains the belts into place also serves to bring the rollers into position to commence marking by gravitation by simply lifting it from the surface.

Hand Guide for Keyed Instruments.

We give on this page an illustration representing an improved hand guide for keyed instruments, devised by Mr. M. M. Spencer, of Washington, Alameda Co., Cal. The object of the device may be seen at a glance. The main object is to give a rest for the hand, to keep it in a proper position, so that the beginner shall learn to strike the keys properly. It will assist young persons when they are being taught the correct way to hold the hands. Many teachers will recollect the difficulty they experience in teaching young beginners to give the right motion with the hand and wrist, and this invention will lessen these difficulties.



SPENCER'S IMPROVED HAND GUIDE FOR MUSICAL INSTRUMENTS.

If the keys are struck by the fingers properly, it follows that the wrist will be in the proper position.

The clamps, etc., of this apparatus are of wood, the bar being made of steel. Where the bar fits into the slot it rests on a piece of rubber, which can be raised or lowered to suit varying lengths of fingers in different persons. The device is arranged to fit upon any square piano, and the inventor claims that by its use six months' time is saved in elementary instruction on the piano. He can be addressed for further particulars as above.

AN Industrial Institute has been organized in San Jose, Santa Clara county. Any person in the county of Santa Clara engaged in manufacturing or producing any article for sale, either by mechanical or chemical process, or engaged in the business of horticulture, floriculture or viniculture, may become a member of the Association upon subscribing to the constitution and by-laws. The Institute will be governed by a Board of Directors. The meetings will be held on the first Wednesday of each month. The following were elected as officers for the ensuing year: President, John W. Coombs; Directors, H. A. Kienette, R. F. Peckham, Robert Page, Albert Lake, C. S. Creydenwise and D. B. Moody; Secretary, S. J. Hinds.

THE hoisting works on the Blue lead, above Willow valley, Nevada county, were burned last week. The fire is supposed to have been the work of an incendiary.

An Improved Dry Amalgamator.

Dr. Edwin J. Fraser, of this city, has recently patented, through the agency connected with this office, an improvement on an amalgamator previously patented by him and described some time since in the PRESS. The machine first patented consisted of one or more cylinders rotated inside of a box, which was partially filled with quicksilver. The cylinders were provided with projecting longitudinal wings or buckets, which served to carry the dry pulverized ore, as it was fed into the box under the surface of the quicksilver and around the opposite side of the cylinder, where it was released and allowed to run through the quicksilver to the surface, the object being to ensure the contact of the particles of metal with the quicksilver.

The improvement consists in the employment of a submerged shaking screen on the discharge side of the cylinder or cylinders, through which the particles of ore have to pass in rising to the surface of the quicksilver, and thus be separated or scattered, so as to ensure the contact of every particle with the quicksilver and prevent the too sudden rising of the particles or masses from carrying off quicksilver through the discharge spout.

Below the surface of the quicksilver or the tailing chamber of the box, or next to the rotating cylinders, is mounted the screen; and to this screen is imparted a shaking motion, so that the particles of ore, when they leave the cylinder and attempt to rise to the surface of the quicksilver, will be caught by this shaking screen and scattered, and the force of their upward movement broken for the purpose above mentioned.

A SAND BLAST machine may now be seen in operation at Heverin's marble yard, on Jackson street, between Montgomery and Sansome. It was brought to this coast by Sumner C. Bugbee. We will shortly give a detailed description of this machine for the benefit of those who are unable to examine it.

THE railroads, telegraph lines, bridges and stock have been heavy sufferers by the late storm, which appears to have been general throughout the State. These losses are but trifling, however, when compared with the benefits which will result to the farmers and miners.

THE Virginia Relief Committee, at a meeting last Thursday, telegraphed to San Francisco for a large amount of wearing apparel and groceries. They also decided that they would need about $10,000 in coin a month through the winter.

New Mineral Districts and Mining Enterprises in Central Nevada.

A correspondent sends us a cheerful account of mines and operations in Hot creek, Tybo and adjacent districts in Nye county, Nevada. The discovery of rich ores in that neighborhood is not a new thing, but dates back nine years or more. The retarding causes common in these far off districts appear, however, to have been more potent there than usual, nearly defeating the efforts of the early prospectors to keep their foothold in the country. Under the great changes since wrought it has become possible for miners to more thoroughly examine that region, which promises to more than realize the expectations first entertained of it.

The surface ores first found in the Hot creek district were of a very high grade. But all the miners having left during the White Pine excitement, the mill put up in the district in the summer of 1868 following them, but little was done here until a year or two since, and now it would appear better prospects than ever before have been struck and the miners are calling for another mill, some furnaces also being required for smelting ores.

From Tybo, twelve miles further south in the same range of mountains, the reports are especially encouraging. Here a large population has been gathered, towns, mills and furnaces built, and bullion is being produced in quantities. The Tybo Consolidated mining company, with but one of the several furnaces they intend to run in operation, and before their large mill, about completed, has yet started up, are turning out $60,000 per month, not more than a tithe of what their mine could be made to produce with reduction works of sufficient capacity, such as they design erecting at an early period. This company, in a liberal outlay of money, have laid here the foundation for a large and profitable mining business and will have earned in a legitimate way any success, however large, that may attend their wisely applied means and well directed efforts.

The mining estate of this company embraces a large number of claims, either one of which would in itself constitute a good operative property, two or three of these claims being possessed of a merit not less pronounced than the best mines at Eureka. One of these mines, the "Two G," so called, has been opened by means of numerous shafts, drifts, cross-cuts and tunnels, to a vertical depth of 323 feet—388 on the incline, and with this course of the vein 800 feet, these workings having developed several chimneys of ore of high grade and great magnitude.

So encouraging do the inhabitants of Tybo consider this prospect of the district that they are earnestly agitating the question of an early extension to that point of the narrow gauge railroad lately completed from Palisade to Eureka. The mineral developments being made in the Hot creek and Tybo regions will be no surprise to those who have ever visited that country or kept themselves well posted in regard to it. In fact, only capital and increased facilities for transportation, and the various improvements lately effected in the business of mining itself, have been necessary to start this remote section of Nevada into life, as these same advantages will serve to open up also other rich mineral districts in the distant and now isolated portions of that State.

RIVER AND HARBOR IMPROVEMENT.—The following are among the appropriations asked for the fiscal year ending June 30th, 1877, in the report of the Chief of Engineers of California: San Francisco harbor: for Fort point, $60,000; for Lime point, $60,000; for San Diego, $50,000; Fort Canby, Columbia river, $15,000; for improvement of Oakland harbor, $250,000; improvement of Wilmington breakwater, $100,000; Sacramento and Feather rivers, $200,000; Upper Willamette (Oregon), $50,000.

A PUBLIC trial of the Mindeleff process, recently described in the PRESS, was given this week. The engineers have reported formally on this process, and we will next week publish an abstract of the report.

CORRESPONDENCE.

Mining Matters in Colorado.

MESSRS EDITORS:—Mining in Colorsdo shows a steady snd uniform progress, with a rapid increase in the yield of bullion. It is no lonsgr csrried on as in ths olden time, but with the csre snd skill requisite for success in sny ordinsry line of business, and the beneficisl effects of this chsnge are everywhere evident. All of the older districts are being stesdily developed and made to prodnce largely in silver and gold. These Rocky mountains have not been hslf prospected yet, snd new mining belts of great riobness are fouud every season.

In 1874 Colorado turned out $3 086,023 in silver, $2,176,624 in gold, $100,197 in copper, and $73,676 in lead, or a total of $5,436,520. The production of the past ten months has already exceeded these figures, and that for tbe year will be between $7,000,000 aud $8,000,000, or second only to that of California and Nevsda. Gilpin county in the same time has alresdy shipped more gold than the entire prodoct of 1874, which was $1,836,000.

Gilpin county is the oldest and richest of the gold districts, with Central, a city of 4,000 inhabitants, as its metropolis. Here in a spsce two miles long by one half mile wide are some thousands of gold quartz lodes, only a part of which hsve proved productive, which, notwithstanding drawbscks snd temporary suspensions, have yielded $27,000,000 since the first discoveries of 1859. The Gregory and Bobtail have each produced over $3,000,000, aud tbe Gunnell and Kansas nearly as much. The Burroughs, Leavitt, Briggs, Illinois, Bates, California, Roderick Dhu and others have also proved surpassingly rich and very remunerative. Owing to various causes these snd other mines were worked only about half the time previous to 1874.

The extrsvagance, ignorance and worthless processes of former yesrs have given place to skill and ecocomy in mining, and gratifyiug profits are now obtained in place of loss and disaster. All of the above named mines are worked to depths of from 500 to 800 feet, and the veins are found to improve steadily in size and value as depth is gained. Many claims or small properties are being consolidated under one management, and a vast saving is effected thereby. What is needed here, and more especially in the newer districts, is capitsl for the development of mines and the erection of mills and reducing works. Eastern companiea who operated here generally failed, and work is now mostly conducted by Colorado miners, most of whom sta'ted in without money, but who have generally been very successful. The causes of former failures were due to the fact that the cost of labor and supplies were three or four times as much ten years ago as they are at present, and from ignorance of the nature of Colorado ores, and also on account of many worthless processes introdnced.

In the lsrger mines at Central gold ores csn be mined snd hoisted for $2 per ton, and milling costs about $2 more, while expenses of coal, wood, transportation, etc., are about $1 additional, making the total outlay per ton, $5. The smaller mines cannot be worked quite ss cheaply. Where ores are milled by other parties than the mine owners the cost is abont one dollar additional per ton. The ores of Gilpin county usually yield under tbe stamps from $5 to $20 per ton, although double and trebie the last figure is ofteu obtained. From many of tbe mines about ten per cent. of the mineral can be selected as it comes from the shaft tbat is rich enough to sell to the smelting works, where it brings from $50 to $150 per ton, being honght on the basis of a charge of $35 per ton for treatment.

At Central, the Bobtail employs 100 men in the mine (worked through a 1200-foot tunnel) and 30 men at the mills and elsewhere; also 90 stamps, and 75 tons of ore are mined and milled daily of sn average value of $10 per ton. Some ore is also sold to the smelting works, and altogether a profit of $10,000 or $12,000 is derived monthly. Monthly cost for coal, $1,500; labor, $7,000; other expenses, $2,500. The Briggs brothers' part of the Gregory and Briggs mines, 1,000 feet long, is worked to a depth of from 500 to 700 feet, employs 60 men and 50 donble issue stamps, mining and milling 50 tons of $8 ore daily. The total expense here is a little less thsn $5 per ton, the mill being immediately over the miue. The remaiuder of this lode produces nearly as much. The Knnsas and Burroughs, 3,000 feet under one manssement, produces nearly $20,000 monthly. The Gunnell, Fiske, Kent County snd Gregory Second lodes have all developed large bodies of rich orc recently, yieldiug from $15 to $40 per ton, and each of tbese mines is now turning out $15,000 per month in gold. A hundred other lodes are worked that yield from $10,000 down to a few hundreds per month.

Except in the case of the Briggs mill, all of these stamp mills are run at the slow rate of from twenty to thirty-five drops of the stamps per minute, it being claimed that a slow rate of speed saves more gold in this region than a fast one. About fifty per cent. of the gold contained in ths ore is ususlly saved. During the year ths sversge number of stamps kept in motion is over 600, locsted in 23 mills, crnshing 125,000 tons of ore worth $1,250,000, as near as csn be estimated.

There are many less extensive gold districts thst are in a prosperone condition. The Gilpin County district has not been so except at intervals, until within the last eighteen months. The recent encouraging developmeuts and retnrns have really been but a work of prepsration for the greater operations to follow. All of ths leading mines show rich ore bodies in ths lowest workings, which hss cansed a general revival in businsss and among the mines.

Twenty milee southwest of Central is Gsorgetown, with 4,000 people and the best developed silver mines of Colorado. In this county (Clear Creek) 12,000 lodes have been recorded, hundreds of which have already proved very valuable. In 1866, the first year of silver mining, the silver prodnct was $500. In 1874 the silver yield was $2,266,000, obtsined from 9,490 tons of ore, giving the enormous aversge of $237 per ton. The lodes hsve veins from a tew inches to ten feet wide, snd the crevices are, on some lodes, 40 and 50 feet wide. The gold lodes of Central range from two to twelve feet wide. The Dives or Pelican lode, near Georgetown, is the best silver lead yet fonnd in Colorado, bnt is mostly shut down by litigation. It has produced $60,000 in a single week, and has a million dollars' worth of ore in sight. The Terrible gsve a profit of $88,000 last year, emnloying 100 men. The Hukill, Colorado Central and eeveral other mines did nearly as well.

The Georgetown mines will turn ont over $3,000,000 for the yesr 1875. The value of the ore shipped to the Esst and to Europe during tbe last ten months is nesrly $1,500,000. There are three reducing mills, one using the Bruckner cylindere and two the reverb ratory furnaces. They will turn out silver bricks to the value of $1,000,000 during the year.

The Boston aud Colorado smelting works at Black Hawk, Gilpio county, have the Swansea process snd ship silver bricks 999 fine to the valne of $1,500.000 this year. Thia comes from the silver mines of Clear Creek, Park and Boulder counties. They also annually ship matte to Boston for separation contsining gold to the value of $600,000, chiefly from the mines about Central.

On both sides of the msin range of the Rocky mountains, immediately south and west of Georgetown are the Snmmit County and Hall Valley silver mines, having very lsrge and rich veins, but from their inaccessibility having yet been but little developed. Still further south are the Park County or Mount Lincoln mines that yielded $596,392 in silver in 1874. Here is a branch of the Boston and Colorado smelting works, and another similar establishment has lately started up also chlorination works. The Moose, Hiawatha, Dolly Varden snd other lodes are enormously rich. The character of these ore deposits resemble those of Utah as far as "pitch" and direction go. Mining at this point dstes from 1871.

Twenty miles northwest of Central are the Caribon silver mines, and here is a hill that is one vast network of silver veins. The Caribou mine employs nearly 100 men, yields twelve tons of ore daily, worth $80 to $100 per ton, treated at the company's reducing works, where Bruckner cylinders are used. The product of the mine for the year will reach $350,000. The cost per ton of treating the ore is about $8. Main shaft is 500 feet deep, with immense quautities of ore in all the lower workings—crevices from four to eight feet wide. This mine was purchased in 1873 for $3,000,000 by the mining company Nederland of Holland. The No Name, Sberman, Native Silver, Idaho, Potosi and Poorman lodes show eqnally as well as the Cariboo did at the same depths, and are paying handsomely. The No Name chlorination works will start up next week. In the same county (Boulder,) are the recent wonderful telluride discoveries, that in some cases show wonderfully rich streaks or narrow veins of gold, but the main portion of ore treated givea a yield of several hundred dollars per ton.

Silver ores are treated at a charge of $35 per ton or are bought on that basis. Where the miuers own their own mills, as in the csse of the Pelican and Caribou, the expense of treating their own ore varies from $7 to $20 per ton, according to the character of the ores. The actual cost of other processes here is said to be from $15 to $20 per ton, except in the cases of the chlorinization works, and of blast furnaces, whiob are much less. Many of the latter are running at various points in Colorado, those at Golden being the most extensive. Large smelting works are also being built at Golden. Rosita, in Southern Colorado, has grown to be a place of 1,200 people from the development of its silver mines during the past two years. In Southwestern Colorado, among lofty ranges of mountains, is tbe San Juan silver region, surpassing all others in extent, breadth of lodes, and as a general thing in value of assays. Bot little bullion has yet been produced, owing to lack of works and facilities for transporting ore. Several smelters have lately begun operations there.

The placer and gulch mines of Colorado are worked out in many plaoes, but rich localities still exist and produce altogether from $300,000 to $400,000 annually. Chinamen are employed in several creeks and gulches.

A mining stock board has lately been established in Denver. Its operations are yet small but are steadily increasing. F.

Central, Colorado, Nov. 24, 1875.

The Missouri Gold Deposits.

The St. Louis *Republican* says: Professor Charles P. Williams, Principal of ths School of Mines at Rolls, returned last evening from an examination of the Mscon county gold placers, and is registered at ths Southern.

The Professor msde tbe exploration by request of Governor Hsrdin, who was in receipt of numerous letters from the new El Dorsdo requesting him to send np ths Stste Geologist to maks a scientific examiuation of the localities where the gold was fonnd.

Of course the Geological Board wae abolished by ths Legislatnrs last winter, and what wss left of the survey was transferrsd to the Rolls School of Miues, and Professor Williams may be considered as filling the position of State Geologist under the present very restricted and economicsl system. He is witbal an experienced ecientist, at the hesd of a corps of able instructors in the various branches of applied science, and very properly the Governor referred the letters to him with the request that he might satisfy the inquiries of his correspondents by an examination.

As Professor Williams will make a report to the Governor of his examination and analysis of the specimens brought away, he is until thst time very nnwilling to be committed to any opinion respecting the quantity, etc., which he hss or may hereafter form. He, however, imparted some general information regarding the formation in which the gold is found, of an interesting character. The Professor left St. Louis on Friday lsst, and has spent the intervening time in the exsmination of several localities in Macon county. He has taken samples from seventeen different localitiee for the purpose of assay on his return to Rolls, so as to obtsin the approximate yield to the cnbic ysrd.

The gold occurs in very fiue particles in the drift formation. The formation is composed of three strata of gravel, all giving gold in the psn, but as to whether it exists in paying quantities remains yet to be seen.

The drift covers a large area, extending from Mscon county northerly beyond the Iowa line. It is disclosed mostly along the Great Cbariton river; and from the fsct that the appesrance of the gold is widely dispersed, it being fonnd near Kirksville, in Adair county, where the most excitement prevails, places the euppositon thst there has been "salting" done out of the question. The underlying rook belongs to the carboniferous formstion.

The drift was transported to its present place from a direction west of north, and in the opinion of the Professor the parent beds could be doubtless traced to Minnesota.

The gold-bearing drift extends abont to the southern limit of the boulder zoue. Boulders of varions sizes are fonnd in the drift, of grsnite, sienite, hornblende, greenstone, trap and quartzite mixed with small pebbles of chalcedony aud rubies—some speoimens of which the Professor bronght away with him. The drift formation is estimsted is by him to be on an aversge sixty-four feet in thickness, forming in many places low hills seamed with gullies aud gulches, in which the "color" is sought for. Water for washing the gold in several localities is scarce, bnt ooald be brought there should the expense be justified.

Sheep Ranch District.

The Calaveras *Chronicle* says that in this district powerful stesm hoisting works are being erected on the well known Wallace & Ferguson mine. The machinery is now upon the ground, and being placed in position with all the dispatch possible. The engine is 45-horse power—of sufficient capacity to admit of sinking to any required depth. The ledge—the yield of which has been remarkable from the ontset—has been mined to the depth of 125 feet, a distance of 1,400 feet in length, without the aid of machinery. The mine has been very successfully worked for a number of yeara, and is to-day one of the most valuable mining properties in the State. When the new hoisting works are completed operations will be pushed with greater vigor, and on a more extensive scale than ever. Work is going actively forward at the Woods mine. Siuking has reached a depth of about 200 feet, the quartz having been of a fair quality from the snrface down. The scarcity of water during the dry season rendered it impossible to run but a portion of the stampa of the mill connected with the mine, but as that impediment no longer exists, the entire battery will be kept in motion in the future. The prospects of the mine are excellent. Splendid ore is being takeu from the Calaveras mine, located near the Woods. A new shaft is being snnk, which has reached a depth of about 175 feet. The old shaft is 400 feet deep. The ledge is a very wide one, all good milling ore. A fine 20-stamp mill is owned in connection with the mine. Work is being energetically pushed with good results.

CARE IN HANDLING MACHINERY.—The general thoughtless handling of machines, oleaning parts of machines while in motioo, adjusting parts which should be at rest while being acted on, and other habits contracted by familiarity, should be avoided. A machine ought not to be trifled with. It has no remorse or pity. Once in its power, there is no escape with impnnity. It should be msnaged with caution and constsnt care, for in dealing with mschinery it is always better to be foolishly careful than foolishly careless.

New Rules of the San Francisco Stock and Exchange Board.

At a recent meeting of the Ssn Frsncisco Stock and Exchsnge Board, the following additional rulee governing the transsotion of business by its membsrs were adopted:

No assembly of members of this hoard outside the board rooms, for the transaction of stock husiuess, shsll at any time be allowed, snd ths rooms shall remsin open for ths holding of iuformal sessions during such hours, between 10 o'clock A. M. and 5 P. M., as shall not be requried for ths regnlar sessions of the hoard. All trsnsactions msds during such informal eessions may be recorded in a book kept for the purposs, and after having been initisted by the psrties thereto, shall bs binding in the same manner as those of the regolar sessions. Any adjournment of the bosrd shall affect its informal as well ss its regular sessions, and the hoard rooms shall remain closed duriug the whole time of such adjournment.

The assistant secretary shall be in attendauce during the informal sessions of this bosrd to record all transactions at the request of members.

All receipts and deliveries reqnired by the purchase and sale of shares of stock must be made directly between the members of this board; and any member who shall, in completion of such stock transactions, either receive the certificates from or deliver them to any person other thsn a member of thie board, shall be fined $500 for the first offense, and for the second shall be expelled.

Whenever the members of this board shall have assembled for tbe transaction of stock business, it shall be the duty of esch member in every transaction with non-members to demand the name of some other member of this board as his broker for the completion of the ssme, and in case of a violation of this rule on tbe part of the member, the penalty for the first offense shall be a fine of $500, and for the second offense expulsion. In the event that the non-member does not give the nsme of a member of this bosrd as his broker, or in the event the broker so named shall fail to complete suoh contract according to the rules of this board, immediately after its having been made, the trsnssction with such non-member may, at the option of the member, be oonsidered null and void. Stock transactions inside the bosrd room can only be completed between members thereof, snd visitors trading among themselves must give to eacb other respectively the name of some member of this board ss their broker.

The admission ticket is issued on conditiou thst the holder thereof will abide by all the rnles and regulations of the San Francisco Stock and Exchange Board, and for any violation thereof, the board reserves the right to cancel the ssme and deuy the holder admission to the rooms of the hoard.

No member of this bosrd shall employ directly or indirectly a non-member to buy or sell mining stocks dealt in at the bosrd, under a penalty of one thousand dollars for each offence.

Prospects in Plumas County.

The Plnmas *National*, in spesking of "hard times," says: We hear on all sides the cry of "hsrd times," "money scarce," "awful dull," etc., and occasionally some poor devil seems to think that the conntry is in a bsd way, and is likely to collapse or "bnst." We don't believe anything of the kind. For two or three good reasons, just at this time there is a heavy pressure, and a scsrcity of money. The past season has been a very poor one for the hydranlio miners, and as they phrase it, "there hse not been water enough to drink," consequnently that source of revenue has almost entirely failed, and the farmers, who have been blessed with abundant crops, are selling them off for a small part cash and the balauce on time. The failure of the water season, and the two money panics in San Francisco have almost entirely stopped the outlay of money by ontside parties in the mines. Another thing which works toward a scarcity is that the merchants have been purchasing large stocks of winter gooda and supplies, and have taken out pretty muoh all the ready money in the conntry. There is only oue way—"scratch along." The heavy rains of the past week would indicate that the water sesson will be a good one, and already the miners are commeucing active operations again. In a short time the riffles will be yielding the precions metals, and aa the majority of the claims are all in good condition for work, we may reasonably expect a successful season. The good results will start up the outside capitalists, and money will again be plenty, and the cry of "hard times" be only a "memory of the past." The hidden mineral resonrces of Plumas have only just commenced to be developed. It has a futnre second to no mining county in the State, and it is folly to snccumb to the "blnes," simply because the present season is a little hard.

GAIN IN CATTLE.—Upon this question one of onr exchanges ssys: "It takes eleven pounds of milk to add one ponnd of live weight to a calf, and an ox that weighs 1,300 pounds will consnme twenty-two pounds of hay in twenty-four honrs to keep from losing weight. If he is to fatten he mnst have just twice that amount, when he will gain two ponnds a day. This is one pound live weight to eleven ponnds good hay. To obtain fifty cents a hundred for his hay, a farmer must sell fat steere at $5.50 per hundred poonds.

SCIENTIFIC PROGRESS.

Black Oxide of Manganese for Destroying Noxious Gases.

Don Juliné de Valmaginl, of Vienna, claims to have discovered a new and valnable disinfectant in the ordinary black oxide of manganese. In tbe *Bayerisches Industrie* he writes as follows:

It is well known that ozone is the only snbatance which will rapidly decompose badly smelling gases; bnt np to this time we possess no metbod of preparing ozone cheaply and in large quantities. I bave fonnd by a series of experimenta that ozone is present in black oxide nf manganese in largo quantities, and that it is continually regenerated. It was not bitherto known that many kinds of oxide of manganese (manganite, pyrolusite, etc.) were ozone carriers; bnt I can prove that they not only possess all tbe properties of the known ozone bearers, bnt are excellently adapted to nse in all cases where ozone haa proved usefnl.

(*a*) Ozeno test paper, prepared with starch and iodide of potassinm, is immediately blued by the liberation of iodine without any acid being addod.

(*b*) A solntion of chemically puro iodide of potassinm, is at once decomposed hy dropping into it a fragmeot or aome of tbe pulverized mineral, tbe liberated iodine turning the solution brown. Tbe liberated iodine is recognized by all its reactions, such as turning hlue witb starch paste, dissolving in chloroform or bisulphide of carbon, subliming at the boiling temperature, aod the characteristic odor.

(*c*) Chemically pnre hinoxide of manganese, prepared artificially, shows the same reaction in chemically pnro iodide of potassium as given above at *b*, reacting jnat like tbe natural prodnct.

(*d*) When the pnlverized mineral is strewn npon chemically pnre silver and moisteoed, tbe silver is browned at once hy tbe formation nf oxide of silver; on heating, the brown spot entirely disappears, proving that it was not sulphide of silver which was formed.

(*e*) The air is also ozonized by contact with the snrface of tbe miueral or of the powder.

(*f*) The reaction abont to be mentioned now was indeed known, bnt was never considered as an ozone reaction, namely: Tincture of guaiacum is colored deep hloe by the oxide of manganese.

(*g*) Black oxide of manganese is also well adapted, by its ozonizing power, to destroy putrid gases, such as sulphuretted hydrogen, and pntrefactive gases, and that too in a short time.

From this it may he concluded that many kinds of manganese ores could meet with extensive nse for sanitary and building purposes.

SONOROUS FLAMES.—M. Dechorme, in the *Comptes Rendus*, reports some interesting observations on the prodnction of sonnds by blowing throngh a tnbe into a flame. He considers that the action of the air is chemical rather than mechanical, and that the sonnd results from small explosions that are prodnced incessantly on combination of the oxygen of the air with the hydrogen or carhon of tbe flame, in incomplete combustion. For the sound to occnr, the presence of air, or of an inert gas mixed with the oxygen, seems necessary. In one of his experiments the white flame from a Bunsen bnrner, with the lateral apertures closed, gave a very strong sonud when blown into with a tube, whereas the blne flame produced when the apertures are open gave a very weak one, or none at all. Carbonic acid alone, or nitrogen, or oxygeo, or chlorine, blown into a flame of ordinary gas, gave little or no sound; protoxide of nitrogen gave a weak sonnd, bnt more acnte than that obtained from air.

ANALYZING SOUND.—A curious instrument has been exhibited before the Academy of Sciences, which is called by its inventor an "analyzing cornet." What is commonly termed sonnd is, as is well known, made np of an infinite nnmber of mnsical notes, and these the cornet in qnestion is designed to analyze, just as a prism separates a ray of white light into its colored components. In appearsnce the instrument is described as resembling a trumpet, having a nozzle to fit to the ear, instead of a monthpiece, and furnished with holes like a clarioeet. Provided with an instrument of this kind, it is said that the roaring of a cataract or the howling of a tempest may be resolved by the listener, skilled in the necessary fingering, into the softest melody, which is heard, however, by himself only.

THE POPULAR BELIEF that lightning will not strike a heech tree receives additional support from the following: In a recent thunder shower in Goshen a beech and a maple standing near together, with branches interlocking each other, received an electric bolt from a passing cloud which shattered the maple and passed into the earth through a prostrate hemlock lying near, which was stripped of its bark nearly the whole length. No trace of the lightning was left npon the beech.

THE PRACTICAL VALUE OF SCIENCE.—When the cultivation of cochineal was introduced into the Canary islands in 1840, tbe prodnct was worth twelve francs per Spanish pound; but mainly owing to the increased nse of aniline colors, first made known to the world by a German scientist, the price fell to four francs in 1870, and to two and a half francs in 1873.

Muscle and Gunpowder.

In the *Journal* for April, 1874, we explained how tbe amonnt of work tbat food is capable of performing is calculated, and how this theoretical amount compares with the work actnally done by the human machine. According to the data tben assumed, the effective result is about one-fifth of what ought to be obtained hy tbe combnstion of the food. If this is less than we might have expected, it is better than is found in the case of the atoam engine, the "nsefnl effect" of which is only from three to ten per cent. of what the transformation of the heat of the fnel ioto work ought to yield.

According to calculations recently made by M. de Saint-Robert, and communicated by him to the *Revue Scientifique*, the work done by gunpowder in modern fire-arms is rolatively much greater than the best results obtained with the steam-engine, and nearly eqnals the average of the human machine.

According to Moleschott's estimate, the combnstion of tho average daily food of a laborer ought to yield a mechanical equivalent of abont 8,880,000 foot-ponnds; bnt tbe average work he does is only ahont 2,000,000 foot-ponods. In other words, tbo "usefnl effect" is ahout 22 per cent of the total available work. Helmholtz estimates the external work of a man as one-fifth of the mechanical power contained in his food.

Fire-arms, like the human hody, are machines for converting heat into motion, the heat being obtained by the combnstion of gunpowder. The gases evolved in this combnstion give motion to the projectile by their expansive force, and at the same time a certain amonnt of heat disappears, heing transformed into work. Tbe total work accomplished by the powder, independent of the recoil, is eqnal to "the prodnct of the weight of the projectile hy the hight to which it would rise if projected vertically in a vacnnm." The "useful effect" is measured by the ratio between tbis work aod the mechanical eqnivalent of the heat set free by the combnstion of the charge.

If we take for illnstration, as M. de Saint-Robert does, a rifled cannon, whose bore has a diameter of 7.5 centimetres (ahout 3 inches) and wbich fires a shell weighing 3.7 kilogrammes (ahont 8.14 ponnds) with a charge of .55 of a kilogramme (abont 1.21 ponnds) of powder, experiment shows that the velocity of the shell when it leaves tbe gun is abont 400 metres, or 1,300 feet, per second. The hight from which it would have to fall to acquire this velocity is 8,158 metres, or abont 26,600 feet; and multiplying this by the weight of the ball, the work actnally done by the powder is found to be about 216,500 foot-pounds.

On the other hand, the calculated mechanical eqnivalent of the heat evolvod hy the combustion of .55 of s kilogrsmme of gunpowder is abont 1,050,000 foot-ponnds. Comparing this possible work with the actual work as just given, we find the nseful effect of the cannon to he hetween 20 and 21 per cent., or a trifle less than the reanlt already found for the human machine.

The comparative cost in money of the work done in the two cases is quite another qoestion. Of conrse the gunpowder hnrnt in the cannon is a mnch cheaper fuel than the food consumed by the msn. In this respect the steam-engine, though it utilizes a smaller percentage of the heat from its fuel, has a decided advantage over the hnman machine. Assuming that the labor of eight men is eqnivalent to one horse power of the engine, it is evident that the cost of the former will be many times greater than that of the latter.—*Journal of Chemistry.*

Magnetization of Ilmenite.

Dr. T. L. Phipson says: "Some fine specimens of ilmenite (titanic ironstone) having been sent to my laboratory from Norway, it seemed a good opportunity to investigate the magoetic properties of this mineral. The composition of that which served in my experiments was: Titanic acid, 24.60; protoxide of iron, 72.10; Fe S_2, 2.06; manganese, trace; silicic acid, 1.24. Total, 100.

"Its specific gravity was 4.8, and it acted with tolerable energy npon the magnetic needle. From the inspection of this action, I concluded that it was possessed of a very considerable number of poles in close proximity to each other, so tbat scarcely two closely adjacent parts acted in the same manner npon the north pole of the needle; hence it was evidently built up by a mass of crystals. An elongated rectangular piece of this mineral was separated by a blow of a hammer; it measnred 1¼ inches in length and was abont ¾ inch broad. This was placed npoo a table and submitted to magnetization by friction with good magnets for upwards of an hour. It was then found to have a pole at each extremity, which it certainly had not before, and was accordingly snspended to a piece of silk, and hung up in a quiet corner of the laboratory. It pointed constantly towards the north, and returned to that position when deviated. It continued to do so for some weeks; but one morning I found it pointing east-west, or nearly so; it had lost its acquired magnetism entirely, having retained it for rather more than a month.

"This loss occurred rather suddenly, and I believe that it coincided with a magnetic storm of some intensity which happened about the time. If these experiments could he continued by some who have more time to devote to them, they might lead to some interesting results. It is possible that some minerals that show action npon the needle might he made magoetic in the above manner."—*Chemical News.*

MECHANICAL PROGRESS.

Admitting Steam into the Cylinder.

The *Journal of the Franklin Institute*, in alluding to the statement in the text books that "It is desirable to open the steam ports and admit steam at the end of the cylinder toward which the piston is moving, before the latter has completed its stroke," pronounces this statement incorrect, and adds:

"The extreme difficulty of eliminating erroneous statements from previous publications, or from translated originals, especially after the many reiterations of error, is exemplified in the preceding qnotation from a recent text book.

"The original statement, made hy good English authority abont the years 1830 to 1835, has held its place in all text books of succeeding date, has gone to misinform German students on its travels, and has come to America, translated, to impart error here. As a general assertion it may be correct that 'it is essential, in order to insure good action of tbe steam, that a maximum cylindor pressnre shall be obtained at tbe very commeocement of the stroke,' but as applied to a rnnning engine it is altogether erroneous.

"For easy motion of an engine, the prevention of shocks and relief of bearings from excessivo pressure (and consequent friction and loss of power), it is desirable that as the piston approaches the end of its stroke the exhaust shall have been closed, so as to form a cushion that will absorb tbe momentnm of the reciprocating parts, and relieve the pressure on tbe side valve at its time of opening; and the back pressure will then be just that needed to give to tbe moving parts their proper velocity in the other direction. And then, after tbo center is well passed, the pressure of steam should be slowly admitted, reaching a maximum not earlier (perhaps for high pressure non-condensing engines) than 1 15 or 1-12 of the motion of the crank; while tbe cut-off should be effected, both by good action of the steam and for the good action of the engine, instantaneously. It may be possible with small sizes of ports and inadequate cross areas, or great length of passages, that steam cannot follow a piston at high speeds; but such possibility exists only with improper proportions for high speed, and should not be remedied by lead.

"The original statement of forty to forty-five years since, was not incorrect for the time, and, if the conditions are all given, is not incorrect to-day.

"About thirty-five years since the slide valve was made without lap; it just covered tbe ports at both ends. The skill of tho workman was taxed to see how exactly the one steam port should open and the other be closed. The motion then given to the valve was almost coincident to tbat of the crank, and the rate of opening was exceedingly slow, as both crank and eccentric bad just passed their centers. The valve motion was then usually transmitted from the eccentrio to the valve through light rocker arms aod rods, and there was more or less lost motion in the transmission. Under such circumstances there was a reason for lead of the eccentric, as well as valve, and both rule and reason bad a warrant in facts.

"When the lap valves were introduced much difficulty followed, so firmly had the theory of lead been established, but the workmen have long since learned, if the books have not, how to get the thnmp out of a slide valve engine. The effect of throttling the exhaust is in no way a loss of power, but is simply a loss of capacity of the steam cylinder. For a given boiler a little larger cylinder is needed to perform tho same work. There is, however, an absolute loss of steam and power on the back lead of the steam, and its recompense must be found in the ease of working and duration of the engine.

"These remarks do not apply alone to slide valve non-condensing engines. For engines of higher grade, in ecooomy for use of steam, the cutting off of the exhaust is a great practical gain. With twenty-four to twenty-six inches of vacuum, if the exhaust is closed (cut off) at one-fourth or one-third, a back pressure of vapor will pile np in the cylinder, to over one-half an atmosphere, and thns relieve, or partially relieve, the engine of the momentnm of the piston and part; and besides this the coudenser will have been relieved from any leakage of the piston itself, which leakage again will have been saved for effective working of the engine. Leakage of piston packing, witbio the limit of troublesome back pressure, thns becomes tolerable."

THE breaking up of large masses of cast iroo has, as our mechanical readers are well aware, heen a matter of considerable difficulty and expense. This is, however, according to the *Monîteur Scientifique*, now accomplished in the case of large gnns by placing dynamite st the lower end of the gun and filling the bore with water. The explosion of the dynamite, transmitting its force throngh the water, fractures the gun.

THE prodnction of spiegeleisen, which not long ago was confined to Prussia, was first begnn in France at the furnaces of St. Louis, near Marseilles, about 1866, by M. Jardan (who visited the Siegen district in 1864, where he learnt its manufacture), by the introdnction of manganiferous ores from Almeria and Murcia in Spain, Corsica and Algeria.

An Improved Locomotive.

A new engine, known as the Weston locomotive, and built by the Baldwin locomotive works of Philadelphia, has been pnt on the Boston and Albany railroad for trial. A saving of fuel of generally over thirty per cent. is claimed. This is effected by means of a peculiar firebox. In most locomotives, the long flues or pipes connecting the furnace with the smoke stack are directly opposite the door, and much of the fine coal is caught by the draft as soon as thrown into the furnace, and comes ont of the smoke stack in the form of dnst and sparks. With this boiler, however, the invention of a man named Weston, a firebrick arch over most of the furnace keeps down much of the fine stuff, and what does escape has to pursue a zigzag course through a consuming box—where the particles are stopped, and even the smoke is consumed—in front of which are the flues, only six feet long, instead of a dozen as in an ordinary engioo. This much for economy of fuel; and to provide still more for comfort, the smoke stack contains an arrangement by which what few sparks do get that far are carried off to the ground by pipes running beneath the engine. The locomotive is higher than most, and is extremely well proportioned. H. B. Klinger, who has it in charge, has been running it on the western end of the road, and comparing its work with that of the company's engines, with an avorage saving of 46 per cent. in fuel.—*Scientific American.*

A CHEMICAL PROCESS OF CONVERTING IRON INTO STEEL.—The Wilmington papers of a late date describe an exhibition given by Prof. Wm. Field, of that city, of a new process of converting cast iron into steel by chemical process. The process is probably a secret, bnt the manipulation is described. Some hundreds of ponods of ordinary cast iroo were first made, we anppose for purpose of comparison, and then the molten iron was taken in pots and ladles containing from twenty to twenty-five ponods, and "the amalgam" pnt into each. The metal after being stoved waa ready to be cast into molds, and in less than five minntes after the amalgam was put in the iron was converted into steel. A number of articles were cast from the metal—a bar of railroad steel, horse shoes, a razor aud plowshare. The tools were said to be of the best quality. The newspapers report that the steel may he made molleable by this process or as hard as is desired. If a part of the carbon which cast iron contains can be removed by chemical means as described above, the process will prove as valnable in opposition to the Bessemer as the latter was superior in most respects to the process of cementation.

THE causes at work for the destruction of boilers are not always well nnderstood, and the results which follow their operation are sometimes of a startling character. The Washington *Republican* cites the following instance, which occnrred recently on the Mount Vernon steamer *Arrow*: "The engineer, on arriving from Monnt Vernon, informed the captain that there was a slight leak in the boiler, arising from defective bolt heads. The captain promptly determined to have them replaced at once, and accordingly the boiler was 'blown off,' new bolts obtained and fitted in their proper places. Everything was pronounced safe, and the order was about to be given to pump up again, when 'crack' came an unmistakable metallic sound, which denoted more trouble. A short search developed the fact that a plate had broken nearly across its face. It was a clean, new fracture, without any flaw, and no discoverable reason for its occurrence. The plate had been in constant use for two years, and was made of the best material, and rolled especially for this boiler by order of the captain."

STEEL FROM THE ORE—SIEMENS' PROCESS.—Dr. Siemous is now erecting furnaces which will hold charges of ton tons and produco twenty tons of steel in twenty-four hours, by his new process; to effect this, thirty tons of pig and scrap are nsed. According to the *Practical Magazine*, the pig iron is made direct from the ore, dispensing with both blast furnaces and puddling furnaces. Extensive works are being erected at Towcaster, for bringing that very important invention into practice. The possibility of this feat has been long admitted; the need was, a furnace in which reduction could be effected perfectly at a low heat.

DANGERS OF SUPERHEATED STEAM.—The dangers of superheated steam form the subject of a timely article in the latest nnmber of the *American Engineer*. Steam is liable to become superheated, without any indication from the pressure gauge, whenever water gets low enough in boilers to expose the steam to heating surfaces. Superheated steam will in turn communicate its heat to the metal, and ignition may be prodnced wherever felt, wood, or other inflammable substance comes in contact with any portion of the boiler.

THE HIGHEST SUSPENSION BRIDGE.—A wire suspension bridge, which will be the highest structure of the kind in the world, is to be contracted over the Delaware river at Water Gap. Its Pennsylvania anchorage will be the summit of Mount Minsi, Mount Tammany forming the abntment of the New Jersey side. These peaks are 1,600 feet high. The length of the bridge will be 3,000 feet, and its cost $100,000.

Mining Stocks.

Considerable animation has been shown in the stock market this week and several pretty little deals have been made. Nobody seems to know the cause of the rise. Those who are credited with being the controllers of the destinies which govern stocks can or will not ascribe any reason why the market should take the sudden turn it has. There are some who ascribe the advance to the filling of shorts, and there are others who say that after a period of depression a reaction takes place and that the present market is one of those actions, which will be followed by a strong recession. Whatever may be the reasons of the advance, it is a great satisfaction to those who have been "holding for a rise" for the past few months. Rumors are again afloat that the "bank crowd" has control of the California and will carry the next election, which takes place soon. The Woodville collapse astonished some of the holders a good deal after its late heavy rise, and those who were holding for $20 are badly cinched.

The era of investigations still continues. The Woodville purchasers are indignant, and the sellers are correspondingly pleased. The Mansfield investigation, which is assuming shape, promises some interesting developments. Many complain that they have been ciuched, and say that there is no truth in the story that the mine has been purchased by English capitalists for ten dollars per share. If the latter should prove to be correct. there will be some lively hauling over the coals of certain individuals.

At the last meeting of the disaffected stockholders of the Niagara Mining Co. over 41,000 shares were represented. This exceeds the number of shares required to overthrow the present management, as only 40,000—two-thirds of the entire stock—was necessary. When the stock has been brought together, then the present secretary of the company, Mr. Townsend, will be directed by the stockholders to call a meeting, and at that meeting new officers will be elected.

The Phil Sheridan and Monumental Companies will probably have an investigation soon and more are to follow. The move is a good one, and those mauagers who are really honest have nothing to fear, while those who have not been faithful will be disgraced in the eyes of the community.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

CABINET M. Co.—Nov. 15. Location: Storey county, Nev. Capital $8,000,000. Trustees—Alex. Badlam, W. T. O'Neale, Eugene W. Cary, M. J. Donovan and E. A. Rowe.

WYOMING COAL AND COKE CO.—Nov. 16. Object: Mining for coal and manufacturing coke therefrom, and buying and selling coal and coke. Directors—Sampson Tams, Wm. Walkesly, Daniel Randolph, Edward S. Smith, Columbus Bartlett, Jas. E. Smith and W. W. Lyman. Capital stock $2,000,000, in 2,500 shares of $50 each.

AMERICAN FLAT M. AND DITCH CO.—Nov. 16. Location: Fiddletown district, Amador county, Cal. Capital stock $5,000,000, in 10,000 shares of $50 each. Directors —W. W. Swadley. J. Craig, Peter Cook, Samuel L. Harrison, R. R Craig, E. B. Jago and R. H. Blake.

WEST BRANCH M. CO.—Nov. 16. Location: Magoolia district, Butte county, Cal. Capital stock $2,000,000. Directors—Roht. Sherwood, J. M. Buffington, J. E. McElvath, Stephen Clis and J. F. Earnest.

SELBY SMELTING AND LEAD CO.—Nov. 15. Object: Smelting, refining, assaying and trading in the precious and useful metals and their ores, and for manufacturing the useful metals in their various forms. Directors —Jas. C. Flood, Wm. S. O'Brien, N. K. Masten, Prentias Selby and Andrew J. Ralston. Capital stock $200.000.

The following company filed a certificate of incorporation at the office of the county clerk of Santa Clara county on the 16th inst:

SANTA CLARA PEAT FUEL CO.—The object for which the corporation is formed is the manufacture and selling of peat, by the process patented by Franklin Dodge, Feb. 2, 1875, and by the machinery invented by him and J. H. I. Tuck. The corporation is to have its principal place of business in San Jose, and is to exist for a term of fifty years. Capital stock $1,500,000, in 1,500 shares of $100 each. Directors—Samuel A. Bishop, J. H. I. Tuck, C. Burrell, J. H. Elwood and Ed. McGowan.

MINING SHAREHOLDERS' DIRECTORY.

MINING SUMMARY.

THE following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

LINCOLN MINE.—Amador *Ledger*, Nov. 20: Both mine and mill are now running full handed. Forty stamps are kept going continually. No more intervals of comparative idleness will occur again for want of water. The large influx of water is trying the new branch ditch. A break occured this week, causing a cessation of work for a few hours. The pumping machinery at the mine is being run solely by water power. This machinery was put up a year ago at a cost of something like $17,000.

SULPHURET WORKS.—C. J. Garland has been compelled to close his sulphuret works at Sutter Creek for lack of sulphurets. The suspension of milling operations for the last two months has enabled him to work up the entire stock of sulphurets he had on hand. Now that the mills are again in full blast, the supply of sulphurets will soon be sufficient to enable the works to start up again. The period of idleness is not likely to extend over two weeks.

MILLS RUNNING.—The Bunker Hill, Original Amador, Volunteer, and we believe the Gover mills have started work again since the plentiful supply of water consequent on the heavy rains of the past two weeks.

CALAVERAS.

HAULING QUARTZ STOPPED.—Calaveras *Chronicle*, Nov. 20: The rains have made the roads so bad up country that the work of hauling rock from the mines to the mills has had to be stopped. There is a large quantity of ore in the dumps of the San Bruno and other mines in the Mosquito district that will have to remain where it is until the roads get better.

GWIN MINE.—The work of putting a new pump into the Gwin mine, that for some time past has been in progress, is nearly completed. It is expected to be in readiness for operation next week. The pump is to be worked by an 80-horse power engine which is in position. Since the commencement of the present storm the volume of water in the mine has considerably increased, rendering it necessary to bail constantly. The hoisting of ore is temporarily interfered with in consequence.

PLENTY OF WATER.—There is water everywhere—oceans of it—overhead and underfoot. Our streets are incipient lakes, the gulches filled with rushing, turbulent, roaring streams and the rivers are swollen almost beyond recognition. The ditch is full to the top of its banks, and if its capacity could be increased indefinitely the water supply would still be equal to the occasion. We take the storm to be the best possible indication of a prosperous season. The rain comes at the right time, there is an abundance of it and no lack of prospects of more in the near future.

EL DORADO.

ACTIVE.—El Dorado Co. *Republican*, Nov. 20: The miners are making active preparations to go to work on various claims as soon as the storm subsides, and will soon be in a condition to swell our finances.

INYO.

WAUCOBA DISTRICT.—Inyo *Independent*, Nov. 13: But little has been heard of this promising district for some time, but notwithstanding all that, the owners have not been idle. They have been doing all they could towards putting things in shape to insure its development. And we have a very good assurance that the time for this work to begin will not be much longer delayed.

PANAMINT.—Numerous Panaminters have been in town this week, but except that all maintain that they have just the most promising camp there is, and that some 75 additional miners are said to have been called for there quite recently,

we have no special items of intereat to record concerning ths camp.

UBEHEBE MINES SOLD.—Ws learn that Messrs. Porter & Hnnter have disposed of a portion lf not all their mining intsresta in Ubehebe district, to San Francisco parties, receiving therefor a good lround sum. We believe that Mr. M. W. Belshaw is ths purchaser. Ths sale includes their wonderfully large and promising copper mine. It has hesn demonstrated that the ores from that mine can be delivered on the dump at a cost not excesding $1 per ton und that they can he easily and profitably worked. Works are to hc erected at once. Our informant believes thut ths prospects for Ubshebe, bstter know as Rosc Spring district, ia second to no nther in the county.

ORES SHIPPED.—We ob.erve qnite u lurge quantity of the rich nres from the Silver Sprout mins piled np at Harris & Rhine's for shipment to San Francisco. Some 30 tons in all have lately heen hrought down for that purposs.

COSO DISTRICT.—Coso *Mining News*, Nov. 20: The devslopments in the loading mines for the past week have been of ths most flattering character, und the prospects for a continuation of the fine orc bodiss ars most highly sncouraging. Work is steadily progressing in the principal mines with as large u forcs in each oue aa can he worked to advantage. Our mines ars now ouly undergoiug snrface prospecting and preliminary opening for more extensive development; and hence the number of men employed is limited to actual needs, and in the near futuro will he largely iucreased. Work on the new furnaces building is progressing as rapidly us the arrival of material will admit of, and we can confidently conut upon having two more engaged in smelting within from two to four weeks from the present writing.

MARIPOSA.

GOLD.—Mariposa *Gazette*: All the boys about town, and not a few men, have turned ont, within the last fow days, to search for gold in the rills and gulches, left exposed by the washing of the water. We have heard of as much aa a dollar being picked up in a few hours hy parties on the search.

PERRIN AND CRAIG QUARTZ VEINS AND MINES.—The ahove miues are sitnated on the north side of the Main Merced river, opposite Reynolds' Cove. These veins of auriferous ore were formerly known as the "Rutherford and Cranherry lodes." Since the discovery of these mines, they have only heen worked at long intervals, aod on a very limited scale. The priucipal work done in 1867 was the sinking of a shaft about fifty feet deep, and running a tunnel to connect with the bottom of the shaft. The vein at the outcropping was narrow, but widened out to ahont three feet at the bottom of the shuft. Abont sixty tons of rock was taken from the mine to u five-stamp mill ahont three-fonrths of a mile distant, on the Main Merced river, owned hy the Rutherford Brothers. We are credibly informed that the rock yielded $40 per ton; hut ure not informed why the work of extracting ore from the mine was discontinued; bnt preaume it was a lack of capital. Should a twenty-stamp or forty-stamp quartz orushing mill he erected at Reynolds' Cove, as is contemplated, und which hus one of the hest water privileges and easiest of utilizing of any in the mining region, it would afford the Rutherford aud Cranberry mines a favorable opportunity to have their rock crushed, and would be profitable for a mill to make an exclusive bnsiness of crushing custom rock, as the country in the immediate vicinity is threaded with gold-hearing quartz veins.

MONTEREY.

CHOLAME QUICKSILVER MINES. — Hollister *Enterprise*: Fount Lecher called on us this week on his return from the Cholume mines, whither he has heen for the past six weeks, constructing a furnace for the Nevada company, and which he has just completed. He built the furnace in forty-one days, turned it over to the owners, who received it and it gives the completest satisfaction. This Nevada mine helongs to Messrs. Eager, Wintera and Goodrich, and is no donht a valnahle property. They have 300 tona of good ore on the dump, and the mine displays endless quantities of mixed ore. There are also other discoveries in that district which promise well. The Nevada mine is sitnated ahout 100 miles sonth of Hollister, in Monterey county. Now that this company have a new and perfect furnace ready for operating, it will not be long before they commence turning ont plenty of metal.

NEVADA.

SHUT DOWN.—*Foothill Tidings*, Nov. 20: The Kentucky mine was shnt down yesterday, probably for the winter. Canse, the failnre of a contractor to snpply wood necessary to make steam to keep the mine free of water. The disappointment to all stockholders will be great, as the mine was rapidly improving as the drift went west.

THE English mine on Badger hill is in full blast. John Quick, Esq., is the superintendent. This, says the San Juan *Times*, is one of the best paying mines in the township. It is worked on an economical basis, and is owned by a nnmber of very clever gentlemen, all Englishmen. An immense amount of money has been realized from this mine doring the past ten years, and it pays hetter now than ever.

WATER RATES.—Nevada *Transcript*, Nov. 19: The hydraulic mines in this vicinity obtain their supply of water for mining from the South Yuha canal company, who have the only principal ditch conveying water here. Twelve cents au inch, miners' measurement, is charged for the twenty-four hours. We learn that the rates have been modified so as to be sight cents an inch for twelve hours dnring the daytime, and four cents an inch during the night. Some of the mines have worked only during ths day, and allowed the water to run to waste or remain idle dnring the night time, hence ths company recently made the change in rates mentioned. This change does not seem to be satisfactory to some, and one owner informs us he will not work his mins unless he can secure a contract from the company so that he can obtain water throughout the season. We understand ths company owning the ditch, dnring the latter part of each season, cut off the anpply at this point, preferring to sell it at points nsarer ths source of the ditch, where they can get sixteen cents au inch for their water, und where ths shrinkage by svaporation, owing to ths long distance it has to run in ditches to get here, is much less. Ths miner hers claims that as he buys water when it is plenty, he ought to be supplied at the same rate when it is scarce, and will not work unless such an arrangement can he made. It is to be hopsd that an amicahls settlement of the question can be mads all round, and that all ths miners will soon be at work with a full hend of water. The country needs the gold lying waste in the banks hereabouts.

PLACER.

THE AUBURN GRAVEL MINE.—Placer *Argus*, Nov. 20: This company cleaned up last Satnrday, after a successful run of several weeks. We were not able to learn the amount of bullion realized, the company keeping that to themselves, but it is nnderstood that all parties were satisfied with the result, and highly encournged with the prospects for the future. Messrs. Gannon, Crowley and Higgins, members of the company, from San Francisco, were here ut the time of the clean-up, and expressed themselves as highly pleased. They left for the city on the Sunday morning train. We believe the company have not yet got to work again, the heavy rain having delayed them in getting ready for another start.

WORK BEGUN.—The splendid rains of the past week have set mining operations going all over the county, and if the promise of a good season holds good, we shall have the most prosperous year ever seen in Placer.

POND & Co., of Todd's valley, started up with four hydraulics the first of the week, and have plenty of water to keep them going. Dull times have ruled for long months in Todd's valley, but the rain has fixed all things right, and now there is plenty of work for all. Idle men with empty pockets no longer fill the streets, waiting for better times.

THE Union ditch company of Yankee Jims had a ditch full of water on Monday, and expected to he able to deliver the miners u full supply.

SACRAMENTO.

FINISHED.—Folsom *Telegraph*, Nov. 20: The North Fork dam was fully completed and the ditch cleaned out some four or five miles down on the line. Water will he running its entire length in about four weeks, when the mines along the river and at Ashland, that have lain quiet for so long, can again be worked. The Ashland mines are good and no douht will pay well. The new dam has been constructed in so substantial a manner that it will withstand any future flood.

SIERRA.

PROSPECTING.—*Mountain Messenger*, Nov. 13: Work has been commenced upon the Johnson ledge, about two miles this side of Ouk ranch. Parties below are interested in the mine and will speedily develop it.

GETTING READY.—Parties are busy digging a ditch to bring water upon the point, opposite Frank Beaver's place, on the South Fork. They are going to hydraulic this winter.

SOME TAKE.—Last week nine and a half onnces of gold was extracted from the Rising Sun gravel claim.

ORO.—The Oro Co. have found a lot of fine rock in their mine. There is some talk of a mill being put up now.

SISKIYOU.

WILL TRY IT SOME MORE.—Yreka *Journal*, Nov. 13: We learn from L. Tickner, the Scott bar expressman, that Bean & Co. will most likely go into their claim on the Klamath river again this season, if no more rain falls. When the Klamath river rose, in consequence of the rain storm a week or two ago, this company's dam withstood the current and did not go down with the other dams. Their wheel, however, was carried away, which will necessitate the building of a new one. The claim was also filled with water. It is thought that they would be able to get in the olaim again in a week or two, and if the rain held off, would be able to work two or three weeks longer in the claim. As they had just got to the pay dirt a week or two before the water drove them ont, this would be quite an object, and enable them most likely to retrieve the losses of the season and perhaps come ont a little ahead.

SOLANO.

QUICKSILVER.—Solano *Times*, Nov. 20: The St. John's quicksilver mining company is making large shipments of quicksilver to San Fraucisco every week, and they are now putting up a thirteen-ton furnace at their mine. The production of quicksilver in this State is indeed surprising, and completely overshadows that of other parts of the world, and exercises a controlling influence on prices. The price has now reached a figure that in many mines just covers the cost of production, and it is said that unless improvement takes place, some of them will be compelled to suspend operations.

TRINITY.

THE STORM. — Trinity *Journal*, Nov. 20: Hopes are entertained that a good winter has begun, ths present being the best storm that has visited us since ths fall of '67. Miners throughout ths county have begnn work with a fair supply of water, and if ths storm will only keep up a few weeks longer our fortunes are made. Everybody being at work makes town particularly dull, but who cares for that, as good times will be the inevitable result of a wet winter, and all can wait for the clean-up of next summer. If the water, now fairly begun, continues as favorable as indicated, we predict a greater gold yield in this county thau ever before. Mines are better prepared for working, and with an emple water supply are bound to yield largely.

Ths above was written on Thursday, when it was raining as though it never would stop. This, Friday, morning the sun rose clear, there being a heavy white frost. Whether the clear-up is permanent, we don't know, but hope not.

Nevada.

WASHOE DISTRICT.

JULIA.—Gold Hill *News*, Nov. 18: Sinking the main shaft is making fine headway, ths bottom being almost entirely in a fine character of quartz. It is now down 70 ft below the 1500-ft level, and it is confidently expected that everything will be in readiness for the opening of the 1600-ft station by the 1st of December next. The main southwest drift on the 1500-ft level is in 70 ft, the face in soft porphyry. The Burleigh drills last evening penetrated the hard porphyry and were driven into a bed of very soft material, but of just what character we have not yet been able to learn. The main southwest drift on the 1400-ft level is steadily advancing, the quartz and ore in the face showing a steady and favorable improvement.

[THE BONANZA MINES are mentioned in another column.—EDS. PRESS.]

ROCK ISLAND.—Sinking the shaft is making excellent headway. The main west drift, on the 650 ft level, is in a fine character of quartz, the face perfectly dry and the running excellent. The quality of the quartz and ore at this point is of a much better character than was encountered at the same point on the level above, so much better that strong hopes are entertained of finding paying bodies when that portion of the ledge is reached where the good prospects were found on the upper levels.

LEO.—Good progress continues to he made in the prospecting drifts from the bottom of the winze 225 ft below the main tunnel level. The face of the main drift is in very promising ledge matter, carrying seams of ore of a good character. A cross-cut was started yesterday from the main drift, and will he driven ahead until the foot-wall is reached. Excellent indications are being met with in the face of the cross-cut.

LADY WASHINGTON.—Sinking the shaft deeper progresses well, the powerful new machinery operating as well as could be desired. All the water that comes in is easily handled by the pumps.

LEVIATHAN.—Still driving ahead north, at the 420-ft level, with the face in fine ore. Two cross-cuts east are being made, which are in 36 ft, in good ore all the way, and no sign of footwall as yet. This shows a valuable and important ore body.

IMPERIAL-EMPIRE.—Daily yield, 40 tons of ore. The ore bresats still show well, and the ore extracted continues of a good milling quality. Average assay of car samples, $58.

GLOBE CONS.—The drift on the ore vein at the third station level is steadily advancing, the ledge increasing in width and showing some excellent quartz and ore.

BELCHER.—Daily yield, 300 tons of ore. The ore breasts are yielding finely, and show no signs of exhaustion. Driving the prospecting drift on the 1600-ft lovel is making fair progress. The air shaft is finished down to the 1400-ft level, and is doing an excellent work in cooling and ventilating the lower levels of the mine.

BULLION.—Enlarging the old incline is making steady headway. The main north drift on the 1700-ft level of the Imperial mine is steadily advancing northward, along the west wall of the ledge, the face in a fine character of ledge material. The air machinery is working splendidly.

YELLOW JACKET.—The north and south drifts from the bottom of the winzes on the 1940-ft level are each steadily advancing in ground perfectly dry and admitting of excellent progress. Prospecting on the 1740-ft level as usual.

GOULD & CURRY.—Owing to the breakage of some of the pumping gear during the first portion of the week, the water rose above the 1700-ft level, stoping all work in that portion of the mine. The damage has been repaired, however, and the water is being gradually reduced to its former level.

CHOLLAR-POTOSI.—Sinking the new combination shaft is making good headway, the ground in the bottom working well. Daily yield, 60 tons of ore, the assay value of which is $28 per ton.

CROWN POINT.—The ore breasts still continue to yield the usual amount of milling ore. The mills on the Carson river are running up to their full crushing capacity.

SUTRO.—The face of the main west tunnel is being steadily advanced. The flow of water is a little on the increase, but is not strong enough to at all impede the headway of the drift.

CALEDONIA.—Sinking the new shaft is making better progress than for some time past. The flow of water is considerable, but not enough to impede progress.

NORTH CONSOLIDATED VIRGINIA.—There is a slight increase in the flow of water, but not enough to at all impede the sinking.

SIERRA NEVADA.—The main west drift on the 1000-ft level is making excellent progress. No new developments.

NEW YORK CONSOLIMATED.—Sinking the main shaft is fairly inaugurated under the most favorable auspices. The station is also being opened for a drift into the merits of a very promising streak or vein of quartz mentioned in last week's report.

LADY BRYAN.—Driving the north and south drifts, on the 380-ft level, goes steadily forward. Sinking the winze below the 250-ft level to connect with the 380-ft level, south drift, is also making rapid progress.

SUTRO TUNNEL.—A very good indication met with during the past week in the face of the header has been a small stream of hot water, nearly hot enough to cook an egg. Total length of tunnel to-day, 11,192 ft.

WOODVILLE CONSOLIDATED.—The erection of the new machinery is going steadily forward without interruption.

OVERMAN.—The main west drift, on the 1100-ft level, is being steadily advanced, the rock in the face blasting tough and hard.

WEST BELCHER.—The main tunnel is now in 340 ft, and squarely into the ledge, which shows 15 ft in width. Excellent assays are obtained, and drifting, north toward the incline, is now on the docket. There is plenty of good pay ore now in sight, the extraction of which will he commenced very shortly.

AMAZON & GLASGOW.—Opening the ledge at the new 260-ft station and level is making excellent progress, the quartz and ore showing more favorable as the work advances.

SULLIVAN—Twenty-five feet advancement has been made in the tunnel since last week's report. Abont 75 ft further to go to connect with the main shaft.

SOUTH COMSTOCK.—Very encouraging material is met with in the face of the cross-cut, and the indications are that the main ore vein, next to the west wall, will he run into before long. Water does not trouble and good working progress is made.

HALE & NORCROSS.—Nothing is being done in the mine at present, owing to a portion of the main shaft needing retimbering.

BEST AND BELCHER.—The breakage of the Gould & Curry pumping machinery interfered somewhat during the week with work on the lower levels. Everything is again in good working shape.

FLORIDA.—Main west drift advancing at a fair rate, notwithstanding water, soft ground and other difficulties. Numerous streaks of quartz assaying richly are being passed through.

SAVAGE.—The water is being steadily drained from the 2200-ft level, and everything is fast assuming a good shape for steady cross-cutting and other working purposes.

NORTH CARSON.—Ore being extracted from the upper workings and hauled to the mill. Lower tunnel getting along first rate, with good ore prospects in the face.

UTAH.—The erection of the new hoisting works and machinery is going steadily forward at as rapid a rate as the state of the weather will permit.

JUSTICE.—Quite an improvement is met with in the main drift and cross-cuts at the 600-ft level, in both quantity and quality.

PROSPECT. — Excellent assays are obtained from the ore streaks continually cut through in the face of the drift.

General News Items.

OWING to the great depression of the iron trade the great firm of Blockow, Vaughn & Co., of Leeds, England, have been compelled to discharge between two and three thousand operatives.

THE Reno *Journal* says that the Central Pacific company have this year paid taxes on the assessed value of $9,000 per mile for their road, without entering a protest against the levy.

A SPECIAL from Philadelphia states that Charley Ross has been found in Connecticut, near the place where Mosher stole the boat in which he made his last cruise.

BRICK POMEROY, proprietor of the *Democrat*, of New York, has suspended. Liabilities estimated at $140,000. No assets.

THE Gnibord excitement at Montreal has completely died out, but the police still guard the grave.

FIVE DOGS, Kern county, wants a postoffice, and its residents have sent a petition to Washington.

A RACE track is being laid out at Visalia, which will cost with the necessary buildings about $20,000.

THE assets of the Selby estate, it is found, will exceed the liabilities by about $500,000.

THE interest in the $30,000 horse race has waned considerably since its postponement.

SAN FRANCISCO hoodlums are becoming more offensive than ever.

MOODY AND SANKEY are "revivaling" in Philadelphia.

THE Mexican annexation business is the topic of the day.

RUMOR says that Bismarck will soon retire from public life.

The Great Epidemic.

Some horse mon declsre that the epizootic is qnite as prevalent in San Francisco at present as during the spring of 1873, thongh all sdmit that it is of a less violent type. This is its prevailing charscter throughont the State, as well as in the Esstern Ststes and Canada. But few cases in this city have ss yet rssulted in death. We observe, however, a growing impression that the end is not yet, and thst the worst is yet to come. The prevailing ides that this is simply a horse disease is, we think, a mistake; for although the supposition that men, women and children have the epizootic is considered a sort of joke, it is, really, anything but enjoyable to those who are thus sffected. From whatever point we view this disesse in connection with man and the horse, it is evident that both are affected in about the same proportion as on its former visit.

We have heard from pretty good anthority that the epizootic is prevailing among swine. This snpposition is also accepted at first as a joke—it seems to soften the asperity of snch convictions to meet thsm half wsy with ridicule—bnt even here the snbject is assuming alserious aspect; for people are already manifesting an nnwillingness to eat pork.

It is possible thst the germs of this disease existed in sll animals now affected by it, requiring only such changes in the weather as have recently occurred to fnlly develop it. It is helieved by msny that the condition of the weather is the primary cause of the epizootic. This, however, is a very superficial view of the matter; bnt to whatever csnse it may be traced, no one can deny that the weather within the last three weeks has been snch as to aggrsvate the form of the disease. Owners of dray and othsr work horses in San Francisco say that exposnre to these frequent rains while the animals are sweating is very injurious to them; and the development, if not the cause of the disease, is in msny csses traced to these exposures. We think San Francisco msy jnstly he credited with taking as good csre of its horses as any other city. Even the street railroad horses of this city sre snbjected to no worse treatment here than in the cities of the East. If the old rule — "adversity tries friends"—is to be accepted as applying to the connection between the horse and those having him in charge, then we may truly ssy thst the horse has good frisnds in San Francisco; for in a majority of cases everything is done that can be done and his labors sre lightened as far as circumstances will allow. As far as practible horses are thoroughly blanketed, especially aronnd the neck. We have sesn horses not in the least affected by the disease having woolen cloths bound ahont their necks as a preventive.

It might have been expected that quackery would avail itssif of sll snch occssions as these visits of the epizootic to sdvertise itself; but, whoever is entitled to the credit, jnstice compels us to declsre that the horses of the country have suffered bnt little from quackery duriug either visit of the epizootic. No ominous specifics hsve heen put npon the market, and those who have written abont the great epidemic have spared advice to a remarkable degree. If we do not meet with much thst is directly availsble in treatment among our exchanges, on the other hsnd there is a noteworthy snd praiseworthy freedom from quackery.

A Rich Quartz Discovery.—Eli Miller and others discovered a very rich qusrtz lsdge near the head of Little Humbug last week. Mr. Kauffman showed us a piece of the quartz which was one of the richest pieces of rock we have ever seen and it was just full of gold. Mr. Kanffmsn informs us that the ledge where discovered is ahout six inches wide, and sll of the same quality of rock. Four pounds of the rock was pounded up and yielded $15. If the ledge widens as it goes down, and the rock remsins of the same quality, this ledge will hecome the best ever discovered in this upper country. The owners, we understand, have commenced, or are abont to, sinking a shaft on the ledge, thongh they will not be able to do much on it this season. As soon as the winter hss passed they will no doubt give it a thorongh prospecting. There are no doubt msny rich quartz ledges not only in the vicinity of Humbng, but elsewhere in the county, which will be bronght to light in the couree of time, and what is needed is capital to thoroughly prospect them. If one-sixteenth of the capital that has been invested in the Nevada mioes had been expended in this county, Siskiyou would stand at the head to-day as a gold producing section. We hsve got the gold, hut it is locked up where we can't get at it without help.—*Yreka Union.*

Child Education.—Let parents not lament because their children do not exbibit uncommon powere of mind in early life, or hecause, compared with some other children, they are deficient in knowledge gained from books. Let them rejoice if their children reach the age of six or seven with well formed hodies, good health, and no vicious tendencies, though they may be at the samo time ignorant of every letter of the alphabet, If they are in this condition, it is not to be inferred that their minds are inferior to those of children who have been constantly instructed. It is a great mistake to suppose that children acquire no knowledge while engaged in voluntary play and amusement.

Health and Happiness.

Health and happiness go together. There is no use talking ahout it, for they do. Not all the medicines or creeds in the world can make a bilious, nervous, sick psrson happy. He mnst be well before he can say, "I sm in good condition ia mind and body." There are a great many wrong notions in the world and everybody hss imbibed some of them. All have prescriptions for whoever complains. Some take this or that nostrum; others lay all nnhappiness to the heart or conscience, while the seat of the tronble is the stomach or liver. And it will be so, long as the world stands, unless a reform he made in our hsbits.

In the first place, a msn's house should be the most healthful, qniet, restfnl spot on earth to him. The religion of a man's life shonld begin here; find its spring and nurture here. All the chnrches under the sun csnnot do or nndo what this home does. When he enters there, and shnts the door behind him, he should feel that the cares, duties, business, noise, smells, and everything else of the outside world are shut out. Here are relaxation and rest. He throws off his formsr life as he throws off his coat. When he sleeps, he shonld do it ss going into the land of forgetfulness to come hack refreshed and new. When he eats, it is to he nourished, the old wastes msde up by newsupplies. When he reads or chats with his family, it should he as he would sit down iu an orchsrd to enjoy its fruits, or in a flower garden to be delighted snd soothed by its beauty and fragrance.

Home should he the club, library, picture-gallery, and sanctuary. But there are msterial arrangements connected wi'h our social life, and not lesst among them are cooking and breathing Poor or partially cooked food will drive heslth ont of the body, and happiness ont of tho hesrt; and had or no ventilation will rnin the pesce of any house. One of the best and greatest blessings in a house is an open fireplace. It is where the members of the family mostly congregate, and are in the best spirits. The hearthstone has witnessed more cheerfulness, and listened to more pleasant words, and seen brighter, happier faces than any other place in the world. The ouly prescription we give is, go snd make yonr home bright and healthful, and it will be happy.—*Investigator.*

The Forehead.

The npright forehead, with its various modifications of squareness and partial curving, generally denotes the sound and noble understandiog, as opposed to the retreating form, which indicates the precise reverse. A merely high forehead does not, however, always imply a good forehead; for the form, proportion, sloping head, arching and position of the hone of the forehead, are tests of the mental power and character. Even the color and smoothness of the skin, together with the lines of wrinkles must be taken into account, for the expression and state of the mind. A perfect forehead should be one-third of the whole face, or equal to the nose in height, the covering skin clearer than the rest of the face, and smooth and free from wrinkles, hsve the power of wrinkling in deep thought, anger, or psin. A forehead, to be perfect, should be, when seen in the profile, neither too arch, nor too square, neither too upright nor too retresting.

The higbor the forehead, the more comprehension and less activity, The moro compressed, firm, and short, (if not too short,) the more concentrated and firm the character. The more curved the top, the moro gentle and flexible the chsracter; while the less curved—that is the more square the top, the more determination, perssverance, and sternness. If the forehead is perfectly npright from the eyebrows to the roots of the hair, there will be a sufficient understsnding; while a projecting forehead will denote imbecility, immaturity, weakness, or stupidity, accordingly as modified by the other features. On the other hand, the pright forehead which is gently arched at the top denotes a calm, cold, deep thinker.

The Way it Rains in Florida.—It is hard for a Northern farmer, who watches the horizon with sching eyes, to understand the clock-like regularity of this rainy season south. Occasionally, as this year, it is delayed; but once set in it goes on regularly. There is a misty or clear morning, the air tranefused with a blushing, rainbowy effulgence that melts away in the ardent kisses of the sun into an intense dazzle of sunlight np to two o'clock. Then the skirmishers of the rain rush in on cool, dewy winds, and by sharp three o'clock the whole line is platoon firing in grest, heavy fusilades. Such rain! Gorgeous, glorious, rnshing, a magnificent enthusiasm of plunging moietnre. Then the long roll of the thnnder drums; the cracking artillery, with its splendor of electric flash, toned off in low rolls; and, hefore you are aware, the mobile srmy has gathered up its splendid wings, its fire and after guard and reservee, and only in the west yon see ite grand victorious battle flags ribbing the sky with broad bands of color. Mix in a few raiobows some foggy mornings when the whole air is prismy, and the clear, still lake looks like an undersky, and you have some idea of Florida in the rainy season. Regular ae the clock that marshalling and grand battle panorama goee on at set two o'clock, to be closed positively — no change on account of the weather—by five o'clock P. M.—*Cincinnati Commercial.*

Women's Wages.

It is a complaint so common as to be monotonous, with those who are seeking to roform social evils, that women receive much less payment for their wsges thsn men. We think there is less fonndation for this reprosch than appears on the surface. In certain fields of employment women crowd the market with half trained lahor, snd in consequence their wages fall to a very low point. They compete with one another. Employers pay less for their lshor thsn for men's because there sre so many of their sex seeking thst particular employment, and, of course, underbidding one another. Moreover, in msny occupations, owing to the chance of their marrying, to their physical weakness and to their want of training, women are worth less than men.

No one who has not sindied the habits of women of ordinary advantages csn realizs how inaccurate aud careless their training is. This is often owing to the want of ambition, or the neglect of their parents. There is in this city, for instance, a very respectable and useful calling for women—teaching in the public schools —by means of which salsries of from $600 to $2,000 per year can be earned. The city offers gratnitously a thrse years' course of careful and thorough trsining for this employmeut in the Normal college. When a graduate has finished this course she is immediately of more valne in the market. Her salary will be probably double what it would be if she undertook to teach without the preliminary training. But we venture to ssy that seventy-five out of the one huudred of those girls who graduate at the city schools, and who mean to be teachers, never enter the Normal college. The usnal alleged reason is poverty. But when one remembers the nnmhers of poor families in New England who deny themselves every luxury to give a boy a good education, one osn essily nnderstand thst the csuse of this neglect in this city is rather want of principle than want of means. The result is that this class of girls soon settle down into ths ranks of poor tosohers, or become shop-girls or sesmstresses.

But even in these places their want of any thoroughness and scenracy of training must at once depress their scsle of payment. For a certain period female assistants were employed in a well known library and reading room of this city. A gentleman hsd occasion to ask for a certain kiud of encyolopedia. The young lady in charge had not the remotest idea what particular encyclopedias were in the reading room, nor even of the character or subject of the journals and magazines. An intelligent office-boy in that positiou would have naturally made it his business to know thoroughly every book and paper in the room. Such a lad at once enters into a successful competition with the young lady, and brings down her wages.

A fow years ago some of onr job printers in New York undertook to employ female compositors. To their dismay they soon discovered that the New York working girls did not know the English lsnguage well enongh, or could not spell accurately enongh, to make good compositors, and they were forced to send for Mssschnsetts female worksrs, or to have the work done in New England.

We may appeal to the common experience of onr lady readers if the female clerks in onr dry goods stores are not more inattentive aud uncivil thsn the male. Such a fact slone (if it be general) would depress their wages as compared with the meu's. Bnt snch defects are merely the result of want of training. The French petty female shop-keepers and clerks sre unsurpassed. And in this conntry, take the branches where women are csrsfnlly educated, and they compete successfully with the other sex. The teachers, for instsnce, prepared by our best female Normal schools aud drilled in the "object system," are more in request for primary and other schools than male teachers. A young lady has been known to receive as high as $1,500 and $2,000 salary soon after graduating. A good Latin teacher in this city can oarn her $2.50 per hour.

Again, in a lower kind of service the pay is excellent. A fair female cook will earn $25 per month and her board, and a skillful one $50, which is better pay than men of the same class receive. We hsve known clever operators on shoe-sewing machines to earn $50 a week; and many just trained on the ordinary sewing machines will make from $1 to $2 per day. A rsw Irish peasant girl will often earn in our families $15 per month, which, with board, is equivalent to nearly $400 per annum. In higher branches there are many female "editors" earning their $1,000 and $5,000 per annnm. The most snccessful woman novelists enjoy a much larger income than this, and the female lecturers receive, in many instances, from $5,000 to $10,000 per annum. Women have no ground whatever for complaining of being "kept down" in the present day.—*N. Y. Times.*

Blackening Sheet Zinc.—The following is a new procees lately discovered for obtaining zinc sheets of a solid black color. The sheet of zinc is cleansed by hydrochloric acid and sand, and then plunged into a solntion of equal parts of chlorate of potash and sulphuric acid. A slight velvety black deposit is immediately formed. The plate is carefully washed with water, allowed to dry, and then plunged into a solution of asphalt in benzine, left to drain, and rubbed with a piece of cotton rag.

An Old Prophecy.

One of our New England exchanges has como across an old almanac, dated 1755, edited by Dr. Nsthaniel Ames, who lived in Dedham, Mass., published in Boston, and in one of its articles Dr. Ames made nse of these prophetic words :

"There lie buried in all this vast region materials for the art and ingenuity of msn to work npon—treasures of immense worth, concealed from the poor, ignorant, aborigins! natives. The curious have observed thst the progress of human literature, like the sun, is from the east to the west; thns it has traveled through Asia and Enrope, and now has arrivcd at the eastern shore of America. As the celestial light of the gospel was directed here by the finger of God, it will donhtless drive the long, loug night of heathenish darkness from America. So arts and science will change the fsce of nature in their tour from hence over the Appalachian Mountains to the western ocean; and as they march through the vast desert, the residence of wild beasts will be broken up and their obscene howl cesse forever, instead of which the stones and trees will danco together at the mnsic of Orphens, the rocks will disolose their hidden gems, and the inestimable treasures of gold and silver be broken. Hnge monntains of ore will bo discovered and vast stores reserved for futnre generations. This metal, more usefnl than gold and silver, will employ millions of hands, not only to form the martial sword aud peaceful share alternately, bnt an iufinity of utensils, improved in the exercise of art and handicraft amoog men. Nature, through sll her works has stamped authority on this law, namely, 'thst all fit matter shall be improved to its best purposes.' Shall not, then, those vast qnarries that teem with mechanic stones—those for strncture be piled into great oities, and those for sculpture into statues to perpetuate the honor of renowned heroes, even those who shall now save their country? Oh! ye nnborn inhabitants of America, shonld this page escape its destined confisgration at the year's end, and those alphsbetical letters remain legible, when your eyes behold the sun after he has rolled the seasons ronnd for a century to come, you will know that in Anno Domini, 1755, we dreamed of your times!"

The Various Parts of a Grapevine.

N. F. Luud, in an address before the Northern Wisconsin sgricultural society, thus defines the principal parts of a grspevine: The stock is the msin part above the root and below whore it branches. The stem includes those portions which have ceased to bear shoots, and are two years old and over. The arm is a portion of the stem trained in a horizontal position. The cane is s ripened shoot, from six to eighteen months old, or until it comes to bear shoots directly from its own buds. The spur is a cane cut short. The shoots are the growth of the current year until the fall of the leaf. Tho laterals spring only from the buds on shoots, and are simply the shoot reproducing itself from its own buds. The nodes are the joints in the shoots and canes from which spring the leaves, buds, tendrils or clustsrs and latersls. The internodes are spaces between the nodes; both these latter disappesr io the stem. The tendril is a twining support. The cluster or bunch is a tendril perfected into fruit. The buds on the shoots occur only at the nodes in the axils of the leaves. Thoy are of two kiuds, growiug side by side. From one springs the latersl, making its growth the onrront year; the othcr remains dormsnt perfecting for the growth of the shoot the coming yesr. Thore are also the blossom-bnds, which appear only on the tendrils and the berries. The whole make up the vine. Let it be borne in mind that the vine has not leaf-buds and fruit-bnds distinctly, like the apple, but leaves and fruit come from the same bud, borne on the shoot, the growth of the present ycar itsolf growing from the hud perfected for that purpose the previous year. No part of the vine which has once borne leaf or fruit will bear it a second time.

Unfermented Wine.—This article is coming quito extensively into use for church purposes, and when mixed with water it also forms a very refreshing summer drink. In order to prepare it the grapes should be allowed to thoroughly ripen. They are then picked and the eteme and all green and rotten grapes removed. The grapes are then crushed and pressed in the neual manner. The juice may be pnt directly into bottles, or it may he first concentrated somewhst by boiliug and then bottled. In either case the bottles are pnt into hot water and bronght to the boiling point, where they are maintained for half an honr. At the end of that time remove them from the fire and cork them tightly while hot, wiring in the corks. Then replace them and continne the hoiling another hour. Glass bottles are hettor for this pnrpose than tin cans, though the latter may be nsed. An analysis of a specimen prepared in New Jersey gave the following result: Alcohol, none; engar and extract, 23.00; ash, .40; water, 76.60. This had probably been concentrated somewhat before bottling. The flavor was fine. Some acid tartarate of potassium had crystallized ont.—*Journal of Chemistry.*

It is estimated that Minnesota will have about 22,000,000 bushels of wheat for export, and that the season'e crops will realize the sum of $30,000,000.

Useful Information.

Vanilla.

The word "vanilla" is frequently on the lips and the peculiar taste of it on the tongue, but few of the thousands who indulge in the delicious ice or delusive soda know anything about the flavor that is so grateful to their palate. The liquid known as "vanilla" is extracted from a bean which grows in considerable abundance in the interior of Mexico. In its green state it is about ten inches in length, as big round as one's finger, and bears a reasonblance to our string bean. When dried and prepared for the market it is about the size of a lead pencil, of a dark-brown color, and with a very aromatic odor. On being cut or squeezed a black tar-like substance oozes out, which, on examination, proves to be innumerable little seeds, so small as scarcely to be distinguished by the naked eye. These beans are cultivated exclusively by the Mexican Indians, a very lawless, treacherous race; so much so, indeed, that a Boston gentleman who recently traveled through the vanilla bean region found it necessary to be accompanied by a strong bodyguard.

The vanilla is indigenous to Mexico, and cannot with any success be cultivated elsewhere. When gathered and dried the Indians bring them to Tuxpan, where they are shipped abroad, one Boston manufacturer alone taking as much as thirty or forty thousand dollars' worth at a time. The demand for vanilla extract has increased so much of late years, not only for creams and soda water, but for cooking purposes generally, that the price has rapidly advanced, while rose extract, long so popular, has correspondingly declined. Another cause for the rapid rise in price is the liability of the bean to mildew or otherwise to become unfit for use. Owing to the increased cost of the article spurious compounds are being thrown upon the market, prepared principally from the tonqua bean, costing the manufacturer less than one-twentieth part as much as the genuine vanilla bean. It is a nauseating substitute, never intended for the human stomach, but can be readily detected by its odor.

Utilization of Cobwebs.

Cobwebs have been applied to various uses. The delicate cross-hairs in the telescopes of surveying instruments are fine webs taken from spiders of species that are specially selected for their production of an excellent quality of this material. The spider, when caught, is made to spin his thread by tossing him from hand to hand. In case he is indisposed to furnish the article, the end is attached to a piece of wire which is doubled into two parallel lengths, the distance apart exceeding a little the diameter of the instrument. As the spider hangs and descends from this, the web is wound upon it by turning the wire around. The coils are then gummed to the wire and kept for use as required. About a century ago, Boa, of Langue doc, succeeded in making a pair of gloves and a pair of stockings from the thread of the spider. They were very strong, and of a beautiful gray color. Other attempts of the same kind have been made; but Reaumur, who was appointed by the Royal Academy to report on the subject, stated that the web of the spider was not equal to that of the silk worm, either in strength or luster. The cocoons of the latter weigh from three to four grains, so that 2,304 worms produce a pound of silk; but the bags of the spider, when cleaned, do not weigh above the third part of a grain, so that a single silkworm can accomplish the work of twelve spiders.

Elastic Varnish for Ladies' Shoes.—Three pounds of rain water are placed in a pot over the fire, and when well boiling there are added four ounces of white pulverized wax, an ounce of clear, transparent glue in small pieces, two ounces of pulverized gum senegal, two ounces of white soap scraped fine, two ounces of brown pulverized sugar; the ingredients are placed in one by one, and every time stirred up; it is well to take the pot from the fire every time a substance is added, to prevent boiling over; when all is added the pot is removed from the fire; when sufficiently cooled, three ounces of alcohol are added, and finally three ounces of fine Frankfort black, well incorporated by continued stirring. This varnish is put on the leather with a brush, and is very valuable for boots and shoes, as it can afterwards be polished with a large brush like ordinary shoe blacking, shows a high polish and does not soil the clothing.

Hammock System in Cars.—Actual experiment in England has demonstrated the great advantages of the hammock system of conveying invalids by railway. The invalid suffers neither jar nor jolt. It is proposed to extend the benefits of the hammock system to the general traveling public, thus reducing the discomfort of railway travel to the minimum.

German Method of Preserving Wood.—The following method is used in Germany for the preservation of wood: Mix forty parts chalk, fifty resin, four linseed oil, melting them together in an iron pot; then add one part of native oxide of copper and afterward one part of sulphuric acid. Apply with a brush. When dry, this varnish is as hard as a stone.

Useful Cements.

1. Waterproof cement for cast iron pipes, etc. Take equal weights, in dry powder, of burnt lime, Roman cement, pipe clay and loam, and knead the whole with about one-sixth of its weight of linseed oil. An increased proportion of Roman cement improves the quality.

2. Cement which resists moisture and heat, but not the direct application of fire, suitable for gas and steam pipes, etc. Take six parts red lead, two parts white lead, and four parts pipe clay, fine and dry, and mix into a stiff mass with boiled linseed oil.

3. Rust cement for water and steam pipes, steam boilers, etc. Make a stiff paste by mixing two parts sal-ammoniac, thirty-five parts iron borings, one part sulphur, with water, and drive it into the joint with a chisel.

Or, take two parts sal-ammoniac, one part flowers of sulphur, sixty parts of iron chips, and mix with water containing a sixth part of vinegar or a little sulphuric acid.

Or, mix one hundred parts bright iron filings, or fine chips or borings, with one part powdered sal-ammoniac, moistening with water. When prepared, force it into the joints. It will prove serviceable under the action of fire.

4. Cement for the joints of iron stoves. Equal quantities mixed, sifted road ashes, and finely powdered clay with a little salt. When required for use, add water enough to make a thick paste.

5. Iron cement unaffected by a red heat. Take four parts iron filings, two parts clay, one part firebrick; reduce to the size of rape seed, and mix into a thick paste with a saturated solution of salt.

Improvement in Plate Glass.—Messrs. Charles Bussell Gibbs & Co., plate, sheet and looking-glass manufacturers, of London, have just succeeded in producing thin polished plate glass for pictures, etc. The standard thickness of the plate glass now in use is, as many of our readers are doubtless aware, a quarter-inch, but in the warehouse of this firm are to be seen sheets, varying in size from twenty inches by sixteen inches to eighty-five inches by forty-three inches, only an eighth of an inch thick. This glass is quite free from the wavy lines of patent plate or sheet glass, has a beautiful surface, and the color is of the greatest purity. Its superiority over that now in use for covering pictures and prints is obvious. Though a glass of this description has for a long time past been a desideratum, it is only now for the first time produced for sale.

A New Cement.—A French chemist is said to have succeeded in preparing a mineral compound, which is said to be superior to hydraulic lime for uniting stone and resisting the action of water. It becomes as hard as stone, is unchangeable by the air, and is proof against the action of acids. It is made by mixing together 19 lbs. sulphur and 42 lbs. pulverized stoneware and glass; this mixture is exposed to a gentle heat, which melts the sulphur, and then the mass is stirred until it becomes thoroughly homogeneous, when it is run into moulds and allowed to cool. It melts at about 248 deg. F., and may be re-employed without loss of any of its qualities, whenever it is desirable to change the form of an apparatus, by melting at a gentle heat, and operating as with asphalts. At 230 deg. F. it becomes as hard as stone, and preserves its solidity in boiling water.

Good Health.

New Treatment of the Insane.—On the occasion of a recent visit of a party of prominent citizens of Montreal to the new lunatic asylum which has been established by the Sisters of Providence near that city, Dr. Howard, the medical superintendent of the institution, made some remarks upon his method of treatment which will probably excite surprise among a good many of those who have made a special study of mental disease. Dr. Howard said that in his opinion it was impossible to treat lunatics and cure them without liquor. He had tried it, and found that no medicine could be substituted for brandy; nothing which would add in such a material manner to the brain substance. Dr Howard's theory is not new, for the most ancient writers on insanity believed in stimulation, and applied it in the treatment of the insane; but the modern practice runs generally to the use of sedatives. The asylum under Dr Howard's charge has been open for the reception of patients only about six weeks, and he says that thirty-two of his patients have already been discharged cured, while upon his books he has the names of nearly more for whose ultimate recovery he has strong hopes. There were altogether under treatment 417 patients.

There is good reason to believe that contagious diseases are often communicated by dogs, cats, and other household pets. A case of scarlet fever recently occurred in England in which a dog conveyed the disease. He had been the constant companion of a fever patient, and his hair doubtless became impregnated with the malaria.

Fatal Hemorrhage from a Tooth.—A young man named Hannan, living in Coles county, Ill., had a tooth drawn last week, and the hemorrhage was so excessive that he was unable to leave the dentist's office. All efforts to stop the flow of blood failed, and he died.

The Pulse.—In a discussion upon the frequency of the pulse, at a recent meeting of the Clinical Society of London, it was asserted that a slow pulse in no wise interfered with health, and some remarkable cases were mentioned. The most interesting was that of Dr. Hewan, related by himself. Twenty-one years ago, after prolonged study and work, his pulse fell from seventy-two to fifty-five, and he felt very cold; from that time its frequency gradually decreased until about eleven years later, when it was but twenty-four beats per minute. Its present rate is about twenty-eight. Notwithstanding these facts, he has not suffered from fainting, fits, or cold, and is capable of great physical exertion, of which evidence is to be found in his ascent of a high mountain on the continent; and his digestion remains unimpaired. Another speaker said that Napoleon I. had a slow pulse, being from thirty to forty per minute, and a third member mentioned that the rate of a horse's was only sixteen.

Chronic Diarrhœa.—"Well, now, Delia," said aunt, "just you tell her of what cured my son Andrew of chronic diarrhœa, brought on by exposure and improper diet in the army. He had been ailing for a long time, years, when this remedy was tried, and though it has been as much as four years since, he hasn't even had a touch of it. It was this simple thing Andrew took: Peaches, dried with the peeling on, and just kept them by him, eating perhaps four or five pieces a day, sparingly though, and a pound cured him." Another curative, or rather a preventive, of sick headache: When weary, either from travel or otherwise, take a small teaspoonful of Epsom salts, dissolved in pure, cold water, just before going to bed.—*Ohio Farmer.*

The Heroic Cure.—From the Virginia *Chronicle*: Among the few who have reason to be thankful for the fire is a lady whose home was on North C street. She had been bedridden for months, having lost the use of her limbs. When the fire approached her dwelling she was carried out on a blanket, and was as feeble as an infant. Within half an hour, to the amazement of herself and family, she discovered that the use of her limbs had returned, and from that moment she has been a well woman. Her great fright had worked a cure.

Neutralizing Chloroform.—According to Dr. Schuller, of London, the bad effects of chloroform on the *pia mater* are neutralized by nitrate of amyl. This substance, it is stated, even in cases of complete anæsthesia, arrests suffocation, re-establishes normal respiration, and allows the pulse to regain its vigor. This, if demonstrated beyond doubt by further necessary investigations, will be an important discovery, since it tends to neutralize the serious danger which now in many instances attends the use of chloroform.

Curing Dyspepsia.—Dr. W. W. Hall (good authority) says that dyspepsia can be uniformly cured and always avoided by the following rules: Eat thrice a day. Not an atom between meals. Nothing after a noonday dinner, but some cold bread and butter and one cup of hot drink. Spend at least half an hour at each meal. Cut up all the food into pea-sized pieces. Never eat so much as to cause the slightest uncomfortable sensation afterward. Never work or study hard within half an hour of eating.

Plenty of Sleep.—A medical man, discoursing upon sleep, makes this remark: "One man may do with a little less sleep than another; but as a general rule, if you want a clerk, a lieutenant, a lawyer, a physician, a legislator, a judge, a president or a pastor, do not trust your interest to any man who does not take on the average eight good solid hours of sleep out of every twenty-four. Whatever may be his reason for it, if he does not give himself that, he will snap something just when you want him to be strong."

Remedy for Toothache.—The following formula, says *The Practitioner*, seems to be serviceable, as the creosote will have an anæsthetic action, while the ammonia will act in the same way as bicarbonate of sodium, by neutralizing any acid present in the tooth. "Take equal parts of creosote, strong solution of ammonia and tincture of myrrh. A very *small* piece of cotton wool to be soaked in the mixture and put in the hollow of the aching tooth."

Vegetable Acids.—From the pen of A. Jacobi, M. D.:—"Nursing women are often forbidden to eat acids, or fruits, lest the milk should turn sour. Vegetable acids as soon as they are taken up into the blood are converted into alkaline carbonates, long before they could reach the milk glands, therefore their acidity is destroyed. Instead of being avoided, fruits are extremely desirable as articles of food for the nursing women."—*St Louis Medical Journal.*

Curry Unhealthy.—Curry has been discovered to be bad for the complection. Dr. Henderson, writing to an Indian paper, says that all curries are colored with turmeric, and that if habitually eaten they will in course of years affect the fleshy tissue, and ultimately the skin. The jaundiced hue of many Anglo-Indians is not due to sun-burning or any affection of the liver, but results solely from the constant consumption of curries containing turmeric.

Domestic Economy.

A Beefsteak.

The sublime idea of a beefsteak is by no means fixed. In England the *beau ideal* is a rump steak and the "point" where a noble circle of fat encloses a plump triangle of lean, is mostly esteemed. As to the thickness to which these steaks should be cut, doctors differ. A large majority rules in favor of thick steaks, but an intelligent and voracious minority declares for a thickness of half or at most three-quarters of an inch, on the ground that steaks of this thickness require only "one good turn," and when broiled over a clear fire become equally cooked throughout—a condition deemed impossible in those of greater density.

In choosing steaks great regard should be had to the color and grain. Pinky-looking beef is always immature, and if tender, tasteless; while coarse-fibred meat, albeit occasionally of high flavor, gives overmuch exercise to masticators, and is, moreover, apt to put a heavy strain on the digestive organs. In these cases the apparent waste is considerable, but the sublime sensation experienced in devouring the lean amply compensates for any loss incurred by an undue proportion of fat.

Perhaps the principal reason why steaks are so miserably cooked in private houses is that no skill is shown in the management of the fire. A good bright fire topped with charcoal, or, in default of pure carbon, with coke, will produce the intense heat without smoke absolutely necessary to cook a steak to perfection. The bars of the gridiron should be thin and not too close together. When these are thoroughly heated they should be rubbed with a little fat and are then ready to receive the steak, which, after being severed from the parent rump and trimmed, should undergo no preliminary treatment, save a slight dusting with pepper. Salt should never be put upon the steak till it is cooked, as it causes the juices of the meat to flow; and the steak should be turned, and only once turned, and should by no means be prodded with a fork.

All hammering of steaks should be avoided. Turned only once and broiled for about ten minutes over a clear fire, the steak is cooked and should then be sprinkled with salt and served on a hot dish. Confirmed steak eaters insist that nothing, beyond pepper, salt, mustard and horse-radish is needed with a steak except a mealy potato and a slice of stale bread; but the *dicta* of these rigid purists are often set aside in these degenerate days and oyster sauce or fried onions are often served as accompaniments. Mushroom catsup is also liked by many, but should always be made hot. The sight of a human being deluging a prime hot steak with cold catsup arouses stormy emotions in the bosom of a true steak eater.

The practice of cutting steaks from the sirloin prevails in America as well as in France; but although the upper and under portions are often divided into "sirloin steak" and "tenderloin," the truly national custom is to cut clean through the bone and sever both into one piece, which is then called a "porterhouse steak."

These handsome cuts are broiled, and often served with mushrooms, making a capital dish for at least two persons. It must, however, be admitted that in America there exist persons depraved enough not only to fry these magnificent steaks, but like the man who ate asparagus at the wrong end, to pretend that he liked them best that way.

Spanish notions of cookery are hardly worth quoting; but for the sake of variety I may describe the peninsular mode of treatment. Neat slices are cut from the under side of the sirloin; meanwhile, a quantity of onions chopped very fine are put into a frying pan, with a liberal allowance of butter, and allowed to take a slight color. The pan is then drawn back and the pieces of beef, well seasoned with pepper and salt, are put in and fried in the butter. Served with the onions over a quantity of stewed tomatoes these fillets are very eatable when nothing better can be got.

In Vienna it is not uncommon to mince the beef fine, flavor it with pepper, salt, pounded onions and chopped parsley. It is then mixed with eggs to "bind" it, and is formed into the shape of small steaks and fried in butter.

The Saxons mix one part of lean chopped pork with two parts of beef and proceed as above. None of the preparations, however, come strictly under the category of steaks.—*Condensed from London Queen.*

Honey Cakes.—Mix a quart of strained honey with half a pound of powdered white sugar, half a pound of fresh butter and the juice of two oranges or lemons. Warm these ingredients slightly, just enough to soften the butter, and then stir the mixture very hard, adding a grated nutmeg. Mix in gradually two pounds or less of sifted flour, make it into a dough just stiff enough to roll out easily, and beat it well all over with a rolling pin; then roll it out into a large sheet half an inch thick, cut it into round cakes with the top of a tumbler, dipped frequently in flour, lay them in shallow tin pans slightly buttered, and bake them.

To Broil Tomatoes.—Select those not over ripe and cut in halves crosswise, dip the cut side into beaten eggs, then in wheat flour; place on a gridiron whose bars have been greased. As they become burned, turn over and cook skin side until done. Season with butter, salt and pepper upon the egg side and serve upon a platter.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Notices of Recent Patents; Hand Guide for Keyed Instruments; An Improved Dry Amalgamator; New Mineral Districts and Mining Enterprises in Central Nevada, 337. Kaolin and Infusorial Earth; Suspension of Work at White Pine; Our Home Industries, 344. Improved Wood-Carving Machine; To Prevent Shafts Catching Fire, 345. The Concentrating Works at Falun in Sweden; Patents and Inventions, 348.

ILLUSTRATIONS.—Spencer's Improved Hand Guide for Musical Instruments, 337. Improved Wood-Carving Machine, 345.

CORRESPONDENCE.—Mining Matters in Colorado, 338.

SCIENTIFIC PROGRESS.—Black Oxide of Manganese for Destroying Noxious Gases; Sonorous Flames; Analyzing Sound; The Practical Value of Science; Muscle and Gunpowder; Magnetization of Ilmenite, 339.

MECHANICAL PROGRESS.—Admitting Steam into the Cylinder; An Improved Locomotive; A Chemical Process of Converting Iron into Steel; Steel from the Ore—Siemens' Process; Dangers of Superheated Steam; The Highest Suspension Bridge, 339.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 340.

MINING SUMMARY from various counties in California and Nevada, 340–41.

USEFUL INFORMATION.—Vanilla; Utilization of Cobwebs; Elastic Varnish for Ladies' Shoes; Hammock System in Cars; German Method of Preserving Wood; Useful Cements; Improvement in Plate Glass; A New Cement, 343.

GOOD HEALTH.—New Treatment of the Insane; Fatal Hemorrhage from a Tooth; The Pulse; Chronic Diarrhœa; The Heroic Cure; Neutralizing Chloroform; Curing Dyspepsia; Plenty of Sleep; Remedy for Toothache; Vegetable Acids; Curry Unhealthy, 343.

DOMESTIC ECONOMY.—A Beefsteak; Honey Cakes; To Broil Tomatoes, 343.

MISCELLANEOUS.—The Missouri Gold Deposits; Sheep Ranch District; Care in Handling Machinery; New Rules of the San Francisco Stock and Exchange Board; Prospects in Plumas County; Gain in Cattle, 338. The Great Epidemic; A Rich Quartz Discovery; Child Education; Health and Happiness; The Forehead; The Way it Rains in Florida; Women's Wages; Blackening Sheet Zinc; An Old Prophecy; The Various Parts of a Grapevine; Unfermented Wine, 342. The Botany of California; General News Items, 348.

The Steam Pump Trial.

The trial of steam pumps, in competing for the medal of the Mechanics' Institute, took place last week at the pavilion. The committee having charge of the trial have not yet made up their report, but as soon as they have completed their labors, we will publish the details. Suffice it to say for the present, that the "San Francisco steam pump," a California invention, manufactured in this city by W. C. Wilcox, came off victorious over the other competitors. This has been spoken of as the "Wilcox pump," after its inventor, and some people suppose it is the "Wilcox water lifter," an entirely different thing. The two machines and two inventors are entirely distinct and different. The "San Francisco steam pump" is adapted for irrigation, boiler feeding, mining water works and all the purposes to which a first-class pump can be applied. The water lifter was for irrigation only. The "San Francisco steam pump" achieved quite a victory in the trial, the tests being very exhaustive and accurate, and Mr. Wilcox is to be congratulated both as an inventor and manufacturer. A manufactory for these pumps was established some months since in this city, and is now working on them. The results of the trial will bring the "San Francisco" into prominent notice among pump users.

Kaolin and Infusorial Earth.

An item is going the rounds of the press to the effect that very extensive deposits of kaolin have been discovered in Santa Barbara county, in this State. Without attempting to discourage the discoverers or proposed purchasers we suggest that they be very careful to find out whether it is really genuine kaolin before going into it extensively. We have seen some of this Santa Barbara "kaolin" ourselves, and beg leave to state that what was shown us was not kaolin at all.

Two gentlemen called on us recently, one a discoverer of a deposit, and the other an intended purchaser. Both were firmly convinced that the substance they had was genuine porcelain clay, or kaolin. The discoverer had seen plenty of it in the East and Europe and was familiar with the substance. The intended purchaser took his word for it and was convinced also. However, he came with said discoverer to ask some questions relative to its value in California, and whether there were in existence on this coast any porcelain factories which imported the crude material. If not, they intended to go into the business on a large scale, being able to supply the world with a superior article of kaolin at a reasonable price.

Intending to make an item of the matter the writer questioned the gentlemen as to whether they had had an analysis made. To our surprise they said no chemist had examined the earth, but the discoverer was so familiar with it that no doubt existed in their minds. Shortly after they went away the intending purchaser returned alone and asked us if we thought it advisable to have an analysis made. We naturally replied that it was, if he intended putting any money into the proposed enterprise. The writer then accompanied the gentleman to a well-known chemist and metallurgist, who, on examination, pronounced it simply infusorial earth. He said an analysis was not necessary in this case, as many samples of similar character had been submitted to him previously. Under a powerful microscope he showed us the *infusoria* plainly, so the gentleman went away with the impression that he would n't start any porcelain factory just yet.

This particular specimen was from Santa Barbara, and since then we have seen other specimens from different places, slightly varying in appearance, but all of a similar character. Immense beds of infusorial earth exist all over California, but it is of no special value, except for scouring purposes and in the manufacture of giant powder, and in these cases a very small proportionate quantity is used. If any one finds real genuine kaolin or porcelain clay, it would be exceedingly valuable, but no one is apt to make much out of infusorial earth by calling it kaolin, unless by a swindling operation. We write this item to put those on their guard who might be careless in the matter.

Suspension of Work at White Pine.

We are sorry to see that the prospects in White Pine district, Nevada, are so very gloomy, and that so little work is being done. Work has been stopped on the Ward Beecher, Original Hidden Treasure, Mammoth and other prominent mines in the district. B. F. Sherwood, the broker, who died a few weeks since, was a large owner in these properties. Some months since, W. B. Bourne, the capitalist, who was also a large owner, died, and since then work on the mines has been languishing. The *White Pine News* in speaking of the situation states that the mines are owned by a few wealthy stockholders, and for the last three years have only been worked by a small force of men; they also own two or three good mills, among which is the Big Smokey, and they too have laid idle. The cause for this unpleasness on the part of the owners of this property has always been a matter beyond our comprehension. That there has been a large amount of money extracted from the mines there can be no doubt; neither can there be a doubt, if properly managed, that immense wealth is still waiting for further development. The mines are all on Treasure hill, in the same belt with the Eberhardt & Aurora, South Aurora and other valuable properties, all of which are now lying idle, with the exception of the Eberhardt & Aurora, which, we are pleased to state, is being vigorously worked, and has been paying its company at the rate of one hundred thousand dollars per month for the past seven months. With a proper management of the above mentioned mines, all the company's mills could be put to work, and they, too, could be receiving their hundreds of thousands per month. We hope that the old management of this valuable property may change, and that it may fall into the hands of parties who will know when they have got a good thing.

We also see by the *News* that the Hamilton mining and smelting company after a run of twenty seven days closed down their furnaces, having turned out in that time ninety tons of bullion valued at about $20,000 or $22,000. The company does not consider the run as having been a profitable one, owing principally to the extraordinary outlay in starting, and the high prices paid for most of the ores smelted. The assays show that the ores were worked up to ninety per cent throughout the run. Owing to the stoppage of the furnace, work has been suspended on the Fay mine, one of the best smelting mines in the district. The whole force has been discharged and the mine shut down. Unless some of the mines continue work this winter there will be no ore in the spring to start a furnace.

From the present outlook in the camp there will be a number of miners thrown out of employment by the stoppage of work on several prominent mines in the district. In this case the *News* advises the miners to form small companies and lease some of the many good mines now lying idle and work them this winter. By this means they would at least make wages, and in some cases a good deal more. All the ore that can be taken out this season will be wanted in the spring by the furnaces, and coin will be on hand to pay for it. It is better to do this than to spend their earnings in hunting work elsewhere, which at this season of the year will be hard to find in Nevada.

Our Home Industries.

Manufacture of School Furniture.

It is a singular and evident fact, that in five years' time a complete change has occurred in this city in the character and form of furniture as well as in the material employed. Prior to that period our dependency led to constant large shipments from the East or to the manufacture of furniture incomparable to the present productions. This will be more marked as the manufacture progresses. The woods obtained on the Pacific coast have not frequently been accorded the merit they deserve as supplying an article necessary to the manufacture of superior furniture. While we certainly do not claim that our woods excel in any specific manner, we must assume their importance as supplying the place of the best imported, and judge them fully up to the standard of being pronounced first-class. The preparation of the several qualities of lumber is the primary process, and here undoubtedly is contained the elements of subsequent success. The imported (Eastern) lumber, before being used, is subjected to kiln-drying, in the majority of instances. Now the great feature of the California lumber is exemplified in the treatment it receives in process of seasoning. California maple, ash and primavera, the chief productive hard woods on the Pacific coast, should be thoroughly weather seasoned and kept under cover. The duration of time depends entirely upon the condition of material and its ultimate object. The lumber should be so piled as to allow a current of air to pass through the different interstices, each board approximating to the other, but not in actual contact. California ash is superior to our maple, and in process of seasoning is less liable to become "doty," a condition which shows in decay. Heretofore much dissatisfaction existed in employing our woods, they being generally pronounced inferior; and this realized, we are bound to say, from a lack of knowledge concerning the best mode of seasoning lumber. There are extensive forests of fine ash in Washington Territory, we are informed by reliable source, and eventually the lumber regions there will be worked to our advantage and benefit.

School furniture is manufactured in one of the chief establishments of this city, and exclusive one of the kind here, the material employed consisting mainly of California and Oregon ash, maple, Mexican primavera, the latter a light-colored wood, resembling maple somewhat in color. The beauty of the grain consists in a variety of shades, the wood also partaking in appearance that of satin wood. Foreign and domestic veneers also form a portion of the materials. Messrs. Gilbert & Moore inaugurated the employment of California woods, and now chiefly, or almost exclusively, employ ash and maple in the manufacture of school furniture. That the business we treat of rests upon a solid basis, we need only mention that this firm shipped during last summer at the rate of two car loads of pupils' desks per month, the same received from Illinois, in addition to their extensive shipments of goods manufactured in this city, which would about equal the imported in quality and value. During four years, which dates from the control of the business by the present firm, home manufacture of school furniture and employment of lumber obtained on the Pacific coast have been the chief consideration of the firm. Our city possesses three manufactories, all under control of the above firm, Messrs. Gilbert & Moore. In the factories mentioned the majority of employees are Swedes, Germans and Americans, following in number; and wages range from $3 to $3.50 per day. Characteristic with the firm is their desire to initiate our native born into the art of manufacture, and in this direction they have accomplished many satisfactory results.

On account of the peculiar nature of the work which emanates from such an establishment as we allude to, it is impossible to systematize the labor according to any determined standard or division. The bank and office furniture is too often the result of architectural drawings, the same being made to occupy such positions as to oblige the manufacture to be carried on according to pre-conceived ideas. At the salesrooms of Messrs. Gilbert & Moore, No. 219 Bush street, this city, there are numerous evidences of a superior class of teacher's desks and settees made from our native woods, in the manufacture of which this division of labor occurs, as the firm can more properly systematize this branch.

It is worthy of comment that many of the public and private institutions in this State and Oregon were fitted up by this firm, in which fine æsthetical taste was displayed, the lumber used consisting mainly of walnut, and that obtained on the Pacific coast. In this connection we would state that about two years ago there was an attempt made to introduce a Mexican wood which resembled somewhat walnut. It was found to be susceptible of high polish and finish, but being of a soft nature it utterly failed as a substitute for the prime article. We are assured of the value of our lumber by extensive employment of the same. White cedar is now used extensively in the manufacture of the cheaper class of furniture, while our hard woods, such as spruce, white cedar and pine, as they come into more general use, will supersede to some extent walnut. Primavera can be obtained at from 12 to 14 cts. per foot; ash, 7 cts. per foot; and maple at about 5 cts. per foot, the price being quite uniform.

Windmills and Pumps.

The effectiveness of the several descriptions of pumps since the principles, or foundation of our knowledge of hydro-mechanics was first discovered by a pupil of Galileo, has been brought to the fullest maturity, our intelligent mechanics proceeding with the attained benefits of scientific erudition, and unlimited capacity for invention. The most popular method employed by the Greeks was a process depending upon the action of the Archimedean screw. The common suction pump early led ingenious men to procure water from a depth on entirely new principles. The common lifting pump was superseded by double-acting pumps; force pumps being introduced to raise water higher than it could be supported by atmospheric pressure; and double-acting force pumps supply an uninterrupted flow of water. The rotary pump and other successful contrivances of this nature are the emanations of the last quarter of a century.

These facts are only relevant to our subject, inasmuch as they are the natural corollary of the windmill, a species of device to raise water on the plan of the cheapest possible motor—the atmosphere. This motor is effectual; and according to the mechanical contrivance it performs well or ill. Some four establishments in San Francisco prosecute the manufacture with varying degrees of success, the principles of construction being identical, the *modus operandi*, or management of parts differing in such respects as to entitle the manufacturers to some knowledge of mechanical invention. The Excelsior windmill, as manufactured by Messrs. Atwood & Bodwell, presents several features worthy of remark, their windmill operating with equal facility to any here made, and unquestionably being superior to the Eastern mills as regards construction.

It is generally understood, we believe, that Eastern windmills are complicated in their arrangement. Thus they become more liable to disarrangement of the several parts and necessitate a constant repair at a pecuniary value of many dollars. Our windmills and pumps command a somewhat higher price, as they are built more solidly, and as their intrinsic value is better understood. The above firm has been in successful operation for the last thirteen years, and during that time it has supplied upwards of 4,000 windmills and pumps to California alone, which are to-day actively employed. This, in addition to the foreign supply, Mexico, South America, Southwich Islands, Australia, China, Japan, etc.

The Excelsior improved windmill, an adjustable and self regulating contrivance, possesses no complex machinery, but is constituted plain and out of the best materials. There are twelve sizes, with wheel twelve to forty feet in diameter. The chief features of the mill are recognized in the center column, upon which the wheel is mounted, revolving upon its axis on anti-friction balls at the base of column and iron circle in platform, the object attained being a susceptibility of the mill to work under the slightest breeze or air pressure; and in the vane, which lies parallel with the wheel, the chain or rope attachment, at the desire of the manipulator, causing the vane to assume a horizontal position to set the mill in motion, or have it become perpendicular to throw it out of the wind. The principle, as we said, with exception of these distinguishing traits, is the same as in general construction of such apparatus. The largest windmill made by Messrs. Atwood & Bodwell, wheel 40 feet in diameter, is capable of raising 20,000 gallons of water per hour. Their windmills range in price from $85 to $2,000, pumps $33 to $500 and $600. At their establishment, Nos. 211 and 213 Mission street, this city, the manufacture of the Excelsior windmill is carried on, also that of the Stover windmill, an Eastern invention, the right to manufacture which is possessed by this firm. Their employees receive wages ranging from $3.50 to $4 per day. This firm also manufactures extensively Sweep horse powers, with patent draw-spring levers, price from $80 to $140; Little Giant triple gears and double levers for two horses; Excelsior double geared, heavy, for one horse, and Farmers' single geared. The extensive use of windmills in this State naturally causes the manufacture to be carried on according to right principles, as ingenious inventions possessing unquestionable qualities of excellence are bound to come into practical play. And as this climate is particularly adapted to the employment of windmills their manufacture, it is reasonable to suppose, must be practiced here to a better advantage than in the Eastern States, where they are in less general use.

Improved Wood-Carving Machine.

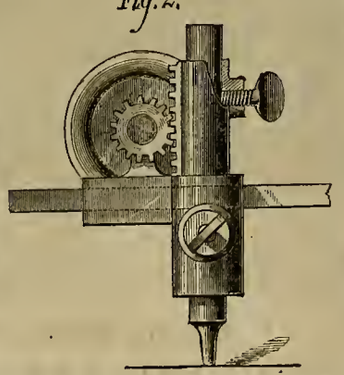
We illustrate herewith a new apparatus designed to perform all kinds of carving, from the coarsest scroll work or similar decoration used upon furniture, down to the pictorial engraving of wood blocks. The principal features of the invention are its simplicity and the ease with which it may be operated, requiring no skilled attention nor especial care other than that involved in the very plain proceeding of following the outlines of a given pattern with a pointer moved by hand. The machine, in construction, is nearly identical with the pantagraph, an instrument used by draftsmen for duplicating drawings on an enlarged or reduced scale, the carving cutters being substituted for the pencil used in that apparatus. *A* is the principal rod or shaft upon which the working part of the device is supported. Its inner end is attached to a sleeve which surrounds the vertical driving shaft, *B*, which serves as a center for the circle, an arc of which is described by the outer extremity of the rod which is mounted on slides or rollers which traverse a curved track upon the table, pivoted, as shown, to collars which slide freely upon the rod, *A*, and which may be adjusted thereon and clamped in position by set screws, or bars, *C* and *D*, of the pantsgraph frame. Said bars are connected by two other pivoted bars, *E* and *F*, which complete the square. The bar, *C*, carries the pattern tracer, *G*, and the extremity of said bar serves as a handle for the workman to guide the tracer into the various curves and indentations of the pattern. Adjustably mounted upon bar, *D*, is a vertical shaft which carries the cutting tool, *H*. Said shaft is driven by a belt from the pulley, *I*, fixed at the central portion of the bar, *D*, which, in turn, is actuated by another belt from the pulley located on the summit of the vertical shaft, *B*. Shaft, *B*, is belted to the driving pulley shown under the table.

It will be obvious that any motion given to the tracer, *G*, will be at once followed by the cutting tool, *H*, so that, for example, if the tracer be moved about the edges of a certain curve, the cutter will follow a like path. The latter, however, will be reduced in size, though in exact proportion, on account of the cutter being located nearer the center of the circle of which the bar, *A*, is the radius, than the tracer. Since the sleeves to which the bars, *C* and *D*, are pivoted are adjustable, it is clear that the nearer the cutter is carried toward the shaft, *B*, the smaller will be the path it describes, corresponding to that moved over by the tracer; and therefore the object, the outlines of which are followed by the latter, may thus be reduced, to any less scale desired, by suitable movements of the sleeve of the bar, *D*, in or out on the rod, *A*.

In the engraving, the machine is represented as carving the scroll work upon a pianoforte leg, which is mounted on centers so that the surfaces to be operated upon may be brought uppermost in succession. The work is always reduced in scale from three-fourths downward, so as to secure greater ease and accuracy in operation; and therefore the pattern, which is shown secured beneath the tracer, *G*, is considerably larger than the article itself, which is fastened beneath the cutter.

Thus far we have referred principally to motions of the tracer and cutter in a horizontal plane. In order, however, to cause the tool to form the raised or indented portions of the work, it is necessary that there should be free movement in a vertical plane, so that, by continuous pressure on the tracer, the cutter may cut downward or be raised to leave certain portions in relief. The bar, *E*, it will be noticed, is very much heavier in construction than bar, *F*. It thus serves as a counterpoise, and balances the frame on centers on the sleeves on bars, *C* and *D*, which surround rod, *A*. The

Fig. 2.



motion of the frame, therefore, is universal; and at the same time, the parts are perfectly balanced in every position, reducing the manual labor of moving it to a minimum. This is probably the most important improvement in the invention, and gives a large advantage over the ordinary routine machine, the motion of the cutter of which is confined to one horizontal plane.

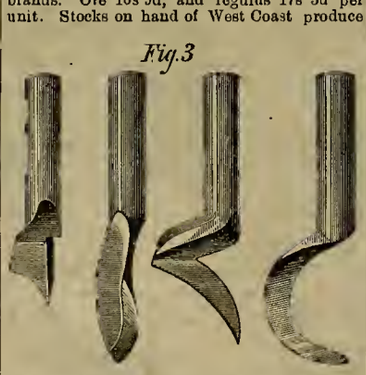
Connected with the upper part of the tracer, *G*, is a small rack, with which engages a pinion operated by a hand wheel. This device is shown more clearly in Fig. 2. Its object is to control the vertical action of the cutter, so that, if desired, it can be prevented from making as deep an indentation as called for by the pattern, or just the reverse. In Fig. 3 several forms of the cutters used are shown.

The capacity of the machine is large, since the table may be built on a more extended arc, thus admitting of an area to be worked over as great as is afforded beneath the cutter, allowing, of course, room for the pattern. The invention is light in all its portions, and easily constructed. It will prove, we think, a valuable aid to workers in wood of all classes. The inventor states that the machine will do the work of twenty expert carvers. For further particulars address the inventor, Mr. John F. Blackman, with Vanderbergh, Wells & Co., corner of Fulton and Dutch streets, New York city.

FIG. 1. BLACKMAN'S WOOD-CARVING MACHINE.

COPPER.—The Liverpool copper market has of late been unusually dull and lifeless. The ruling rate for good ordinary brands during the month of October, has been £82 10s. Quotations on November 1st, according to Jas. Lewis & Son's report were as follows: Bars, £82 to £82 10s for good ordinary brands on the spot and to arrive, and £83 and £84 for special brands. Ore 16s 9d, and regulus 17s 3d per unit. Stocks on hand of West Coast produce

Fig. 3



were 12,435 tons fine, against 13,206 tons on the 1st of October.

THE hoisting works of the Niagara and Monumental mining companies, situated a short distance above Devil's Gate, on Gold canon, Washoe county, were blown down last Saturday night, and were left a total wreck. The same blast that demolished the Episcopal church in Silver City, Lyon county, leveled the hoisting works.

NEARLY all the Virginia fire companies are making arrangements to disband.

To Prevent Shafts Catching Fire.

Mr. W. Ware, one of our oldest subscribers, gives the following suggestions for a method of preventing mining shafts from taking fire, when the mill and hoisting works over the shaft take fire and burn. In the first place, he says, there should be no wood at the top of the shaft, but it should be finished at least the length of one set of timbers with iron, brick or stone. Moreover, there should be no wood on the ground close to the top of the shaft.

Two ordinary iron rails, such as are used for street cars, are taken, and one laid on each side of the mouth of the shaft, so as not to interfere with the hoisting. These rails should be sunk a few inches in the ground. Have a strong iron car with small wheels or rollers to fit the rails, so that it will run easily back and forth, and large enough to cover the mouth of the shaft perfectly and some little to spare. The car should be kept filled with sand or earth and run back out of the way while hoisting operations are going on, but always kept beside the shaft in readiness.

Now, when the alarm of fire is given and the workmen hoisted from the mine, the car loaded with sand should be run over the mouth of the shaft, so as to cover it in the most perfect manner. An embankment of earth can now be thrown up all around the edge of the car so as to make it perfectly air tight and fire proof. The rails should be sunk so that when in position the body of the car will just clear the ground. When properly prepared and kept clear of rubbish the mouth of a mining shaft may be closed in five minutes. For small mines particularly a device of this character would be of great utility, since it would always be in readiness.

THE Virginia *Enterprise* of the 16th says: Night before last, about 10 o'clock, Mathew Paulson, amalgamator at the Devil's Gate mill, Silver City, Lyon county, met with an accident which will undoubtedly prove fatal. He was in some way caught in a belt which he was trying to place on a pulley, and thrown some distance, striking against the corner of a post and crushing in his skull. The physicians called to his assistance have no hope of his recovery.

ALL the horses of the Virginia and Gold Hill omnibus line, and nearly all the work animals in Virginia, are afflicted with the epizooty to such an extent as to render them unfit for service.

ANTIMONY is selling in Liverpool at £58 to £59 for French star regulus.

QUICKSILVER has fallen in Liverpool from £14 10s to £12 per flask.

AMMONIA!
For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.

It is unequalled for cleansing Woolen Fabrics, Cutlery, Carpets or Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing.

It renders water soft, and imparts a delightful sense of coolness after washing.

DIRECTIONS.—For Laundry, use two to four tablespoonfuls to a washtub of water. For bathing, use one tablespoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterward. For stimulating the growth of plants, use a few drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.

Also, SULPHATE OF AMMONIA for chemical purpose, fertilizing, and the preparation of artificial manures. AMMONIACAL PREPARATION, for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing, and PURE LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes.

☞ Manufactured by the
SAN FRANCISCO GAS-LIGHT CO.

OF INTEREST TO

MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially *machinery for mechanical ore concentration*, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for references.

VIRGINIA CITY SUFFERERS' RELIEF FUND.

NOTICE.—All persons who wish to contribute money to the assistance of the sufferers by the late fire in Virginia City, will please make out their checks in the name of GEO. S. DODGE, Treasurer, and leave the same at Rooms 12 or 17, Hayward's Building, California street. Those sending cash will please forward to the same name and destination.

Several solicitors have been appointed, who are provided with pass-books signed by the President, Treasurer and Secretary. The Secretary will be daily in attendance from 9 A. M. to 3 P. M.

HON. J. P. JONES, President.
GEO. S. DODGE, Treasurer.
RICHARD WHEELER, Secretary.

THE MINING AND SCIENTIFIC PRESS is the leading journal of America. New processes and mechanical inventions are illustrated and discussed in its weekly issues. It is a 16-page sheet, handsomely printed, for $4 per year. Dewey & Co., publishers, San Francisco.—[Mt. Lincoln News, Alma, Colorado.

SEWING MACHINES.

REDUCED PRICE, $35.

HOME and HOME SHUTTLE SEWING MACHINES.

Reduced to Live and Let Live Prices.

These Machines are superior to any and all; nice sewers, straight needle, two threads, shuttle, lock-stitch, the simplest and cheapest, and the lightest running first-class Machines in the market. To see is to convince yourselves.

The Hall Treadle for Sewing Machines,

The most important improvement ever made. It saves labor and preserves health. No more diseases and deaths, side or back aches from using Sewing Machines. No teaching required. A child can run it. Always starts the right way. Never goes backwards and breaks things. Can be stopped instantly. With it on your Machine, you can do double the work you can without it. Fifty stitches can be made with one pressure of one foot. It can be applied to any Sewing Machine. Approved by Massachusetts State Board of Health (see Official Report 1872), Massachusetts Medical Society and Massachusetts Charitable Mechanics' Association. The HALL TREADLE is a part of all HOME MACHINES sold by us.

The Hall Treadle Grinding Machine

Must be seen to be appreciated. For a Farmer or Mechanic to see it, is to buy one. It is an indispensable article in every Farm-house, Shop or Hotel.

The Hall Treadle Jig Saw and Boring Machine

Is an accomplishment in every Workshop. The HALL TREADLE is applicable to all machinery requiring foot-power—Sewing Machines, Grindstones, Jig Saws, Turning Lathes, Jewelers' and Dentists' Lathes, etc Send for Circulars.

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR APPLICATION—requiring no thinner or dryer, and will not spoil by standing any length of time.

It is Cheaper, more durable, more Elastic, and produces a more Beautiful Finish than the best of any other Paint.

It will not Fade, Chalk, Crack, or Peel off, and will last twice as long as any other Paint.

In ordering White, state whether for Outside or Inside use, as we manufacture an Inside White (Flat) for inside use, which will not turn yellow, and produces a finish superior to any other White known.

Put up in ¼, ½, 1, 2 and 5 gallon packages, and in Barrels. Sold by the Gallon.

For further information send for Sample Card and Price List, or apply to the office.

SAVE YOUR HORSE'S FEET!

NO MORE RASPING AND HAMMERING TO CLINCH HORSE-SHOE NAILS. TENDER FOOTED HORSES SHOD WITH EASE. EVERY TEAMSTER HIS OWN BLACKSMITH.

The new patent implement used is an attachment to an ordinary pair of pincers. A scoop-shaped graver, or chisel, and a flattened, roughened plate, (formed in one piece) are hinged and fastened on to the handle of the pincers. When the forceps are closed the graver projects from one side of the handle, and is retained in that position by allowing the end of the plate to enter a slot between another plate on the other handle, and the handle, thus holding the graver steadily, while the forceps are grasped by both hands, and the grooves cut in the hoof below the point where the nails come through. When the grooves are cut the handles are opened, and the roughened plate turned outward, thus carrying the graver into a slot in the socket, out of the way.

To clinch the nails after the grooves are cut, the handles are opened, and the roughened plate is put beneath the hoof. The edge of a steel plate on the handle of the forceps is then placed above the nail point, and by closing the handles the nail will be bent down into the groove already cut, where it lies nearly flush with the hoof. The plate can be adjusted for large or small hoofs. The groove cut by the graver is about one-eighth of an inch long and one-eighth of an inch wide. No hammering or rasping is necessary. The foot is not bruised or scarred. Any one can learn to use it in a few minutes. Tender-footed horses can be shod with no pain to them. Further information given, if desired, by CHARLES DONNER, Inventor, or C. F. SUHL, Cor. Commercial & Drumm Sts., S. F. eowbp

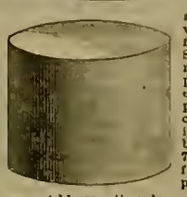
COR. NORTH FIFTEENTH ST.
AND PENNSYLVANIA AVENUE,
Philadelphia, Pennsylvania.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.



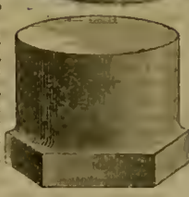
[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.



Address all orders, with dimensions, to W. R. Townsend, Secretary.

54 BUSHELS OF CORN AN HOUR.
HARRISON'S
LIGHT, VERTICAL BURR MILLS
BARBER & BACON, MILLERS AND LUMBER DEALERS, SOUTH VERNON, VT., write July 15th:
"We have been running two of your LIGHT VERTICAL CORN MILLS for the past 6 months with remarkable results, and have ground over 30,000 bushels of corn into No. 1 meal in that time, running the grist-mill nights only, as we run our saw-mill in the day time. We have often ground in the 20-inch Mill (which weighs about 500 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 24,300 lbs., or 434 bushels. To do this we have to run at a speed of 1,300 turns per minute, and use about a 20-horse power. You may refer parties to us for further information, and when we have tested your HEAVY VERTICAL MILL, we shall take great pleasure in giving the results."

The Concentrating Works at Falun in Sweden—Continued.

[Written for the PRESS by CHAS. C. RUEGER.]

The oone of the rotary hnddles oonsists of a donble floor, the lower of one and one-fonrth inch hoards, the upper of one inch.

The pnlp and olearing water is eqnslly distrihnted over the apex of the cone hy means of a circnlar trongh or gutter. Of this gutter, one-third of the circumferenoe is allotted to the pnlp, and two-thirds to the clesring water. For the more perfect cleansing of ths product, moreover, olearing water is run on to the cone from a moveshle gutter plsced over it. On the psriphery of the huddle cone are three sqnirt pipes, at a suitable distance from each other, the first of which is one foot ten inches long, and serves for the washing off of the waste slums; the second, of the same length, for washing off the middlings; and the third, having a length of five feet six inches, serves for the washing off of the concentrsted small ore slum.

The openings in the squirt pipes have s slanting direction of 45° to the radial line, so that the wster issuing under great pressure gives the slnm a rapid motion towards the periphery of the huddle, whereby the clearing of the surface is effected more perfectly, aud since the holes can in this wise he pnt fsrther apart than in the case of the pipes perforated at right angles, the consnmptiou of clearing water is materially reduced.

The huddles yield clean small ore for the smelter, with six to fourteen per cent. copper, hesides middlings, pulp and wsstes.

The first of these products is run on to small endless helt tsbles, which are six feet eight inches loug and two feet two iuches wide, with an inclinstion of one and one-fourth inch per foot. There are fonr of these tables 0.1 to 0.4, or for each buddle one in use at present, which, as csn he seen in the drswing, are set up to each side of the fnnuel tanks. The arrangements for the accumulation of the auriferons small ore are eimilar to thoee hefore described. Reservoire are eunk for this purpose helow the floor at the head end of the table, and snch also are placed at the foot end, for the accumulation of the impoverished small ore.

The middlings from the huddle flow into the fnnnel apparatus *K* 4, where they are condensed, and are then lifted in common with the middlugs from the third gronp of percussion tables, back into the V box *e* 5, hy the aid of the elevator *l* 3.

The flood of wsste pulp paesee the condeneing funnels *K* 3, and is then lifted into the slnice *n*, *n*.

In front of, and to the side of all the fnnnel appsratus are sumps, eunk helow the level of the dressing worke floor, in which the water flowing out of the condensing fnnuele clesrs itself of slum; this mnst therefore be ehoveled out hy hand from time to time. In order that no interruption of the general operations he cansed by this work, there are several enmps, *y*, *y*, into which the water csn be run in the meantime.

For the dissolving or mixing np of the slums, etc., with water, a rotary mixer is nsed, which is set np slongside of the first fnnnel tank. The pulp so obtained is raised hy the elevstor *l* 3 hsck into the V box *e* 5, for sorting and separatiou, while the tough slimes are mixed np hy a second rotary mixer set np alongside the following funnel tank *e* 8, and run directly on to the rotsting huddle *p* 3.

The two funnel tanks, the four rotating hnddles, four endless helt tshles for the extraction of the anriferous small ore, and the rotary mixer alongside the fnnuel tank *e* 8, are in charge of one man hy day and one other hy night.

The digging out of the slnme in the varions sumps and slnices, and the charging of the aame on to the mixer alougside of the fnnnel tank *e* 7, requires ueually one workman, sometimes two by day and one other hy night.

IX.—The Discharge and Transportation of the Wastes.

It is well known to the concentrating man how considerably the digging ont of the waste sands and elume from the sumps, and their further transportation, increases the cost of concentrating operations.

This work, eo ardnons and disagreeable to those employed, is here doue mechanically.

To thie purpoee the flood of waste pulp from the various machinee, ae already mentioned in proper place, rnns firstly into funnel apparatus *K* 2 and *K* 3 for condeneation, and is thereby reduced in quantity. It is then lifted hy the elevator *l* 2 into the transporting eluice *n*, *n*, which carries it into the building *E*.

On each side of this building are eet up a row of eeven tip boxes, *q* 1 to *q* 7. The sides and bottoms of these boxes are made of three inches thick plank, accurately fitted and doweled, and are lined inside with one inch casing hoards; outside the boxee are heavily strapped with iron. The length in the clear is seven feet, the width three feet four iuches, and the depth three feet ten inchee, the capacity of the hoxes therefore 89.4 cnhic feet, or four to four and one-half tone sand.

The front end of the hoxes is hinged to a heavy cre ;) aron top, and is caused to close water tight hy means of two strong wrought iron clasps, carrying two press screws each.

A cross sluice hranches off to esch side of the transporting sluice and reaches over all the tip hoxes. Ahove the center of each hox a small funnel is attsched to the hottom of the cross sluice, into which the sands deposit, and are discharged through the half-inch orifice into the tip hox helow.

The hack end of the hoxes is fast to the sides, and has a nnmher of one and one-half inch holes ahove ons another on its center line. These are olosed while the hox is filling, with the exceptiou of the top one, throngh which the water discharges, and flows into small sumps placed heneath, there to deposit the slum still contained therein.

When one hox is full, the pnlp is tapped off, snd run into the next. To drain off the water as mnch as possihle, the holes in the hack end are opened one hy one. The screws in front are then loosened, the clasps disengaged and the hox tipped up with little exertiou to an inolination of 50°, thereby discharging its contents into a railroad car of five tons capacity plsced heneath.

Generally several hoxes are filling simultaneously, and hy mesns of the funnels in the hottom of the sluice, the weste sands can he separated into several sorts, coarse and fiue. The first of these contsins 0.3 to 0.4 per cent. copper, and is utilized in making mortar, and for several other purposes, or is thrown over the dump. The fine wastes, ahout ten to fifteen per cent. of the whole mass, is richer, aud contains 0.75 to 1 per cent. copper, sometimes even more, but in such a minute stste of division that it is difficnlt to concentrate. It is expected that the percentage of copper in these fine wastes will iu the course of time he decressed, hy suitahle attention snd skill of the operatives.

Experiments are heiug conducted at present to determine if the copper in these slums can he economically extracted hy roasting and lixiviating with sulphuric or muriatic acid.

For the further transportstion of the wastes, a rsil tramway with donble track is nsed, which extends from the hnilding *E* to heyond the dump. It has a length of 650 feet, and the difference in level hetween the places of loading and dumping is 65 feet. The cars are drawn hy wire ropes connected with a hoisting gear in the upper part of the building *E*. When the full car is drawn up, the empty one returns on the side track. The hoisting gear ie run hy an endless wire rope carried over the roof of the main hnilding, and driveu hy the turhine *G*.

For the transportation of the waste rock, which is sepsrated in the work at the picking tahles, snd of the wastes from the sluice *n*, *n*, two men are employed during six hours daily.

In the manner thns desoribed the entire mass of raw materiale moves hy the aid of mechenical appliancee through every stage of the concentrating proces, the valuahle products are separated from the harren rock hy automatic and continuously acting machinee and apparatus, as much as possihle independent of the skill of the workman, and all the products transported to their places of destination aleo hy mechanical means.

Thus may these works he considered the first example of an independent system of concentration, with s continuons action.

The great advantage of snoh works are particularly prominent where, on account of climatic or other circumstancee and conditions, as in Falun, the wages for mannal lahor are comparatively high.

However, of much greater influence on the economic resnlts thau the saving in wages, is the diminntion of the losscs hy concentratiou, which are reduced to a minimum hy the arraugements described.

It might he appreheuded hy some, that in consequence of the great nnmher of mechaniol appliancea the works become too complicated and snhject to frequent interrnptions for repairs, eto. Thia is not the case, because all the machiuee, etc., are carefully and enhstantially made, down to the smallest detail, and of the most durable material obtainahle; and to thie judicioue care it is dne, that the works ran very regularly from the etart, eo that no alterations whatever hecame necessary, and night work could he introduced in a ahort time thereafter, when the employees had hecome somewhat familiar with the handling of the machines.

Althongh the whole works consist of a syetem of simultaneoue operations, the arrangement is such that in case of repaire, or in consequence of a scarcity of water, one or the other part can he stopped without therefore suspending the operations of the whole works. The machines are repaired while the works are in full blast, for everywhere reservoirs are in readiness to receive the respective material in the meantime, or it is given to some of the neighboring machines, so that interruptions are avoided as much as possible.

The manual work requiree no coneiderable exertion, and is done entirely in contract, in euoh a way that the finished ores are paid for hy weight, and in proportion to their copper value.

[To be Continued.]

A RICH strike has heen made in the 500-ft level of the Manhattan miue, Lander county. The ore assaye $3,000 per ton.

THE importe of silver ore into Liverpool in October were ahout 480 tons, and silver-lead ore about eighty-five tons.

ABOUT 600,000 stand arms are exported from the United States annually.

The Botany of California.

It will he remembered hy most of our readers that when the State Geological Survey was stopped, hy action of the Legislsture in failing to make an appropriatiou, the volumes of the reports on Economic Geology and Botsny which were psrtually prepared failed to appear. The State uot pnblishing the volnmes or paying to have the manuscript prepared, some private gentlemen in this city snhscribed $5,000 to complete the work. Those interested in knowing how the work is progressing will he glad to read the following letter from the former chief of the survey, Professor J. D. Whitney, which was resd at the last meeting of the California Acsdemy of Sciences:

CAMBSIDGE, MASS., Nov. 6, 1875.

My Dear Sir: It appears to me proper thst I should furnish you with a statement of the progress of the Botany of California, towards which you have so liherally subscribed, and which will indeed owe its existence to your contrihntions and efforts to make others contrihnte. Professor Gray hes devoted himself exclusively to this work ever since spring, and his part, comprising the *Monopetalœ* is all in type, making about 300 pages. Mr. Watson, hotanist of the Fortieth Parallel Survey and Curator of the Harvard University Herharium, is at work on his share of the volume, the *Polypetalœ*, and from fifty to one hundred pages are in type. I see no reason why the whole volume of six hundred pages, comprising the flowering plants of California, shall not he in type (electrotyped) by January or Febrnsry. Professor Gray received $500 in full for his work, and Mr. Watson gets $200 a month. The $5,000 contributed will, I hope, pay for putting the volume in type aud all the sslsries. I hope, also, that there will he enough left to pay for printing and paper and hinding of 250 copies of the volume. The electrotyping costs just ahout $4 per page on the average. The typography is very handsome, and the work in all respects first olass. Nothing like it has been done on any State survey. The volume will have a high value for all studeute of hotanical science. Profeesor Gray hse devoted himself to it most enthusiastically. Profeesor Brewer was here all summer working on this volnme, and Mr. Watson has given hie whole time to it eince last spring. He receives a living salary for hie work, whioh is necessary, as he hae no means, and hed to lay aside other work to attend to this. Profeesor Brewer chergee only actusl expensee incurred. * * * Of course, I charge nothing. If the money does not hold out to pey for printing the volume I will pay for that myself. * * * The snhscribers could each be furniehed, in thet case, with a few hound copiee to give away, and they would have the plates (electrotyped), which they could offer to the State for five thousand dollars, and which the Legieleture ie sure, *some time or other*, to take off their hands; or, if not then, prohably eome publisher would he glad to get them at that price. From the plates the volnme csn be manufactnred, printed on good paper, and bound for ahout $1.67 per copy." It will he a large and very handsome volume, nniform in size with the other pnblicatione of the survey, hut much more closely printed. Respectfully yours,

J. D. WHITNEY.

HON. S. C. HASTINGS, San Francisco.

It will he seen from this that this valuahle work will soon appear; and it ie to he hoped that it will not be long hefore some provision will be made to pnhlish that map of the pliocene rivere which was prepared, and the volume on Economic Geology, msny facts on which must have heen gathered.

A NEW HARNWARE FIRM.—Mr. James E. Gordon has purchased the hnsiness of Pillsbury, Hussey, Adair & Co., dealers in hardware, northeast corner of Front and Pine streete, iu this city. Mr. Gordon ie well known in the bnsiness, having been head salesman at Linforth, Kellogg & Co.'s for fifteen yeare. A first class hardware business will he done by Mr. Gordon, who brings to hie new poeition energy and ahility, aa well as a most accurate knowledge and extensive experience. The only chain works on thie coast are owned hy Mr. Gordon, the office of which will now he at the store, No. 5 First street. We are glad to see the young men of California coming to the front and going into hueiness for themselves, and wish the new firm success.

NOTWITHSTANDING the etorminess of the weather the work of reconstructing the hnrned works in Virginia is heing pnshed forward at the mines. All that can be accomplished by men who are pntting forth their hest efforts is heing done to get up and inclose the new hnilding of the Consolidated Virginia and Ophir companiee. Great progrese ie heing made.

THE Napa *Register* eays the product of the Pope valley qnicksilver mines has heen, from the first to the present time, ahout $345,000 worth of quicksilver.

THE Kansas and Missonri hridge, which spans the Misesuri at Lesvenworth, is in the hands of a receiver.

No more bodies from the wrecked *Pacific* have been found.

PATENTS & INVENTION

A Weekly List of U. S. Patents sued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Diepatoh, Dated Washingto D. C., Nov. 23, 1875.

ART OF CURING TOBACCO.—James D. Culp, G roy, Cal.

CIGAR MOLN.—James D. Culp, Gilroy, Csl.

———The patents are not ready for delivery by t Patent Office until some 14 days after the date of iss

NOTE.—Copies of U. S. and Foreign Patents furnish by DEWEY & Co., in the shortest time possihle (by t egraph or otherwise) at the lowest rates. All pate business for Pacific coast inventors transacted wi perfect security and in the shortest possihle time.

Affairs on the Comstock.

We notice thet the *Record-Union* sent special correspondent to examine the Virgin mines and ascertsin their condition, as rumo were afloat that many of the mines we flooded. The *Record-Union's* "special" sa that the Consolidsted Virginia snd Californ are entirely cleer of wster to their lowe depths. As far as the Best & Belcher sn Gonld & Curry mines are conoerned, the fac sscertained are thet from the 1550-foot level the Curry there ie an inoline snnk to the dept of 1,550 feet, and from the hottom of this i cline a drift 500 feet long and four feet wi has heen extended into the Beet & Belch ground. Thie drift, owing to the hreaking the Curry pumps, is now full of water, whic rises in the incline to the depth of forty feet su no more.

In Virginia on every hand preparstions fo the coming winter are preesed forwsrd, su phes lsid in, and every guard poseihle ad vanced to ward off future stoppagee and de lays should the storme prove so severe as t stop traneportation over the Sierra. So fa the raine have hsd the good effect of furnishing a hountifnl snpply of water for the mills o the Carson river, permitting them to again ru to their full crnshing capacities. At the Co solidated Virginia mine, according to the Gol Hill *News*, the rebuilding of the hoisting work is advancing at ae rapid a rate as the storm state of the weather will permit; the employee notwithstsnding the heavy rain and snow, st sticking etesdily at work, doing all in the power to keep the erection of the hnildings pr greesing. The frsme of the preeent hoistin works huilding is mnch lsrger and more com modions, being one complete story higher tha the old works were before heiug hurned.

The mine is in excellent condition, a few me heiug kept at work on the different levels watching and strengthening the weak timher wherever any indication of giving way may b oheerved.

On the Ophir the frame of the hoisting work is up and covered in, so that the erection o the machinery can now he carried rapidly fo ward in spite of the stormy weather. Larg ehede for machine and carpenter shops have alao heen covered in, so a considerable portio of the employees can still prosecnte their labor in comparative comfort. A force of men sr kept at work on the 1465 and 1600-foot levels keeping the drifts and ore breasts in good re pair until the hoisting and pnmping machiner ia sgain ready for operation.

In the California mine the flow of water fro the 1400-foot level of the Consolidated Virgini has almost entirely ceased.

VICE PRESIDENT WILSON died on the morn ing of the 22d inst. The President in the orde announcing the death says:—In testimony o respect for the distinguished citizen and faith ful public servant the varions departments o the Government will he olosed ou the day of hi funeral, and the Executive Mansiou and al the Executive Departmente in Washington wil he draped with the hadge of mourning for thirty daye. The Secretaries of War and Navy wil issue ordera that appropriate military and navs honore be rendered to the memory of on whose virtues and services will he long hornr in recollection hy a grateful nation.

The Whole People as with one voice proclaim HALE' HONEY OF HOREHOUND AND TAR the sovereign and in fallible remedy for Coughs, Colds and all Broncial diffi culties. It is the National Specific for pulmonary dis ease.

Pike's Toothache Drops cure in one minute.

WOODWARD'S GARDENS embraces an Aquarium, Muse um, Art Gallery, Conservatories, Tropical Houses Menagerie, Seal Ponds and Skating Rink.

DEWEY & CO.,

American & Foreign Patent Agents,

The best, speediest, and surest method for you to obtain patents, file caveats, or transact any other important business with the Patent Office at Washington, or with foreign countries, is through the agency of DEWEY & CO., PUBLISHERS OF THE MINING AND SCIENTIFIC PRESS, SAN FRANCISCO, an able, responsible, and long-established firm, and the principal agents on this side of the continent. They refer to the thousands of inventors who have patronized them, and to all prominent business men of the Pacific Coast, who are more or less familiar with their reputation as straightforward journalists and patent solicitors and counsellors. We not only more readily apprehend the points and secure much more fully and quickly the patents for our home inventors, but with the influence of our carefully read and extensively circulated journals, we are enabled to illustrate the intrinsic merits of good patents, and secure a due reward to the inventor, besides serving the public who are more ready to give a fair trial, and adopt a good thing, upon the recommendation of honest and intelligent publishers.

To Obtain a Patent.

A well-constructed model is generally first needed, if the invention can well be thus illustrated. It must not exceed 12 inches in length or hight. When practicable, a smaller model is even more desirable. Paint or engrave the name of the article, and the name of the inventor, and his address upon it.

Send the model (by express or other reliable conveyance), plainly addressed, to "DEWEY & Co., MINING AND SCIENTIFIC PRESS OFFICE, SAN FRANCISCO." At the same time, send a full description, embodying all the ideas and claims of the inventor respecting the improvement describing the various parts and their operations.

Also send $15 currency, amount of first fee of the Government. The case will be placed on our regular file, the drawings executed, and the documents made up, and soon sent to the inventor for signing.

As soon as signed and returned to us with the fees then due us, it will be sent straightway to the Patent Office at Washington

For designs no models are necessary. Duplicate drawings are required, and the specifications and other papers should be made up with care and accuracy. In some instances for design patents two photographs, with the negative, answer well instead of drawings.

For further information, send a stamp for our illustrated circular, containing a digest of PATENT LAWS, 112 illustrated mechanical movements, and HINTS AND INSTRUCTIONS regarding the RIGHTS AND PRIVILEGES of inventors and patentees, which will be furnished post paid. Also a copy of NEW PATENT LAW of 1870.

When the invention consists of a new article of manufacture, a medicine, or a new composition, samples of the separated ingredients, sufficient to make the experiment (unless they are of a common and well-known character), and also of the manufactured article itself, must be furnished, with full description of the entire preparation.

For Processes, frequently no model or drawings are necessary. In such case, the applican has only to send us an exact description, an what is desirable to claim.

Address **DEWEY & CO.,**

PUBLISHERS, PATENT AGENTS AND ENGSAVERS,

No. 224 Sansome street, S. F.

"Faith and Confidence"

LIVERMORE, Oct. 1st, 1875.

MESSRS. DEWEY & Co., Patent Solicitors: *Gentlemen*—Yours of the 29th ult. containing my patent to Elevated R. R. duly received, and I hereby return my sincere thanks to the MINING AND SCIENTIFIC PRESS Patent Agency for your promptness and honesty in regard to our business connections. I have received a flood of circulars from Eastern firms, desiring to deal with me, but I have declined any communication with them and prefer, as soon as circumstances will permit, to negotiate with and patronize a home institution; one in which I have full and confidence—DEWEY & Co.

Again thanking you for your promptness in securing my patent, I remain, obediently yours,

WM. H. HARRISON.

At a Stated Term of the Circuit Court

of the United States of America of the Ninth Judicial Circuit in and for the District of California, held at the court room in the city and county of San Francisco, on Thursday, the 30th day of September, in the year of our Lord one thousand eight hundred and seventy-five. Present—The Honorable Lorenzo Sawyer, Judge.

Nicholas Seibert, complainant, vs. Wm. T. Garratt, defendant—In equity.

DECREE.

This cause came in to be heard at the February Term, A. D. 1875, of this Court and was argued by counsel and thereupon upon consideration thereof, it was ordered, adjudged and decreed, as follows, viz: That defendant, William T. Garratt, was not the first or original inventor, or discoverer of the improvement or discovery claimed by him, in and by those certain reissued letters patent of the United States, number five thousand three hundred and twenty-eight (No. 5328), for an alleged new and useful improvement in lubricators, issued to said defendant, William T. Garratt, on the 18th day of March, A. D. 1873, and is not entitled to a patent therefor, and that said reissued letters patent, number five thousand three hundred and twenty-eight (No. 5328) are declared void and the same are hereby vacated and set aside by reason of their interference with those certain letters patent of the United States, number one hundred and eleven thousand eight hundred and eighty-one (No. 111,881) for a new and useful improvement in lubricators, issued to complainant, Nicholas Seibert, on the fourteenth (14th) day of February, A. D. 1871.

It was also further ordered, adjudged and decreed that complainant do have and recover of and from defendant his costs and expenses to be taxed herein.

(Signed) LORENZO SAWYER,
Circuit Judge.

The above decree has reference to "Seibert's Eureka Lubricator" for oiling the valves and cylinders of steam engines.

It has a glass gauge and condensing pipe, or reservoir, with a regulating feed valve, and works as follows: As the water of condensation is admitted, under the oil, just so fast the oil passes out at the top through a pipe into the steam pipe to oil the valves and cylinder.

Parties who infringe or purchase the infringed lubricators, will be held strictly responsible.

N. SEIBERT, Patentee,

Important in regard to Pumps.

Aurora, Nevada, November 10, 1875.

H. P. Gregory & Co., San Francisco.

Gentlemen: I am exceedingly well pleased with the "SPECIAL PATTERN BLAKE MINING PUMP" and its workings; especially so with the "MORTON EJECTOR CONDENSER." Have both in position on 400 foot level. The condenser is doing all that is recommended, and is saving from one and one-half (1 1-2) to one and three-quarters (1 3-4) cords of wood per day, I consider it a very useful improvement.

Yours Respectfully,

Warren Rose, Supt. Juniata Cons. S. M. Co.

We are prepared to put in the "BLAKE IMPROVED STEAM PUMP" in connection with the "MORTON EJECTOR CONDENSER" and fully guarantee a saving of from thirty to forty per cent. over any other direct acting Steam Pump in use.

Very respectfully, DUNCAN BEAUMONT.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Patent Solicitors.

SAN FRANCISCO, SATURDAY, DECEMBER 4, 1875.

VOLUME XXXI Number 23.

Japanese Iron Industry.

Our readers will recollect our having mentioned some months since that the Japanese goverument had ordered extensive machinery from England for the purpose of working certain of the iron mines in Japan. This is the first start of that government in the development of the iron industry of the country. Everything required was ordered for immediately putting up two charcoal blast furnaces at the Heigori iron mines, to be employed in reducing the magnetic iron ores in that district, which contain over sixty per cent. of metallic iron, and resemble greatly the ordinary Norwegian and Swedish ores.

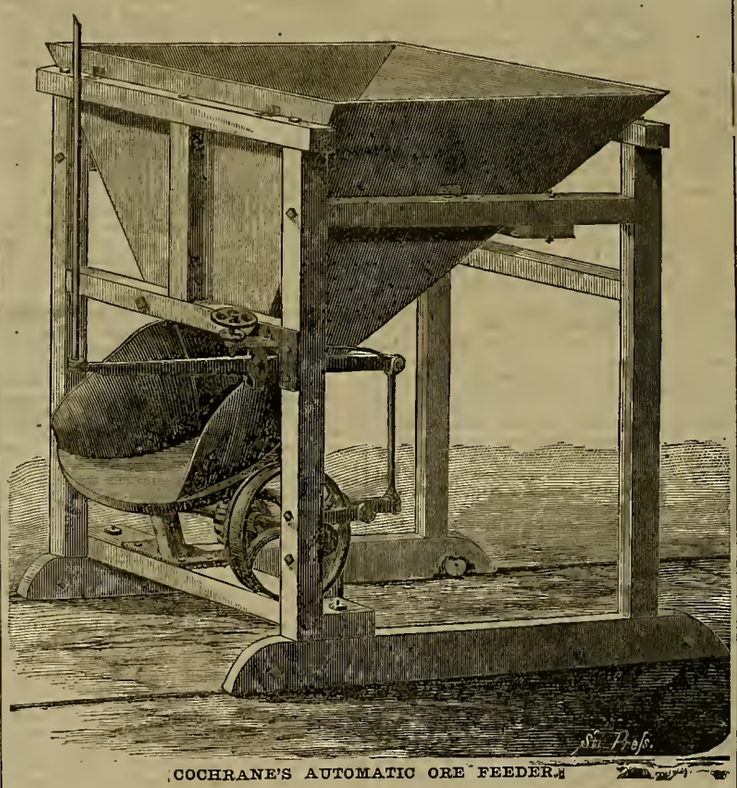
All this plant was shipped last month. The designs and details of the iron works were entrusted by the Japanese government to Mr. David Forbes, F. R. S., who has been for so many years, as consulting engineer, connected with charcoal blast furnaces in Norway, Sweden and Poland. The contract for the iron and brickwork fittings, etc., was placed in the hands of Messrs. Head, Wrightson & Co., of the Teesdale iron works, Stockton-on-Tees, whose patent hydraulic arrangements for lowering the bell are employed, as well as Whitewell's hot-air stoves, Surmaan's closed breast and all the most modern improvements. The blowing engines, which are vertical, as well as the boilers, were constructed by Messrs. Galloway, of Knott mill works, Manchester. The furnaces are to be 57 feet high, 4½ feet diameter in the hearth, 10 feet at the boshes and 6 feet at the month, and will be constructed of Japanese fire brick, with the exception of the lowest 12 feet. They are intended to turn out between 75 and 80 tons of charcoal pig per week each furnace, and to utilize their waste gases for heating the hot blast stoves and the boilers of the blowing engine. This is a very great step in advance for Japan. The plant is the most extensive and improved that could be manufactured, combining everything now known to be of value in iron working. The reputation of the gentleman who designed the details is such as to warrant the belief that no pains were spared to make everything as complete as possible and of the best character. The Japanese have competent men to manage the plant, and no doubt will soon have the whole in working operation.

Rights of Stockholders.

It will be remembered that the Secretary of the Woodville mining company was recently tried in the police court for refusing to allow stockholders to examine the books. This seemed to have little effect, for a resolution was passed by the trustees of the company giving the books into the hands of the President, J. W. Pearson, in such a manner that no one could examine them without permission from him. He then kept out of the way so no one could get at him, and the pending investigation was necessarily suspended. Mr. Pearson was then called upon to appear before Justice Joachimsen to answer the charge of refusing to allow copies of the entries in the book to be made by a stockholder. The latter action was brought under a statute enacted in 1873-4, in which the penalty for the offence charged against Pearson is fixed at $200. A. P. Needles, who has for some time past been acting as attorney for the dissatisfied stockholders, appeared as the complainant. Wednesday the case was tried, and Judge Joachimsen gave judgment for plaintiff, with costs of suit. This is the first case that has been tried under the new statute; Pearson has appealed the case to the County court, and stockholders and managers of mining companies in general will await the decision with interest. It is to be hoped that high handed operations of this sort will be summarily put down, and trustees or other officers who refuse stockholders any information concerning their own property, should be put under a ban. One thing is very certain, if this sort of thing continues much longer, there will not be many stockholders for officers to snub, for people will refuse to have anything to do with such companies. Half of these officers seem to think the mine is run for them to make money out of, not for the interest of stockholders. When they get in office they take possession of everything and look upon the other shareholders only as so many people who have to pay money and have no other rights. It has become almost unbearable, and several investigations now pending will have a fine effect in showing these people up and putting others on their guard. If half a dozen men can run a mine in opposition to half a hundred, especially when the half a hundred pay the expenses, the sooner the half a hundred drop the whole thing the better for them and the community.

An Improved Ore Feeder.

Automatic ore feeders are now considered indispensable pieces of machinery in complete



COCHRANE'S AUTOMATIC ORE FEEDER.

quartz mills, and there are not many large mills where the batteries are fed by hand. It took some time to overcome the prejudices which existed in favor of hand feeding, but after it was found that the machine fed more regularly than men, leaving economy aside, they were more generally adopted.

One serious difficulty, however, which has existed, was in getting machines to feed wet or dry, coarse or fine ore, with equal regularity, and without having to arrange the feed according to the ore in the hopper. Most of the ore feeders in the market have a forward and back shaking motion communicated to them by the drop of the stamps. One objection urged against them is that the feed has to be adjusted too often as the class of ore varies. For instance a load of quartz is dumped into the hopper and the machine feeds beautifully and with regularity. Perhaps the next hopper-full will be earthy matter mixed with lumps of quartz, and all of it more or less wet. Then the feed has to be changed so as to communicate more motion to the shaking table so that the contents of the hopper will be fed under the stamps fast enough. This soft earthy matter is, of course, crushed faster than hard quartz, while at the same time it feeds slower from the feeder, so, in order to keep the stamps properly fed under these circumstances, the machine has to be frequently adjusted.

Mr. T. A. Cochrane, a gentleman who has had an extended experience in mining machinery and especially in the direction of ore feeders, has recently contrived a "carrier" feeder which does away with the shaking motion and feeds regularly any class of ore by a very simple mechanism. These machines are now being manufactured by Joshua Hendy, No. 32 Fremont street, where one of them can now be seen in operation. This feeder, which is herewith illustrated, took the premium at the late Mechanics' Institute fair.

The mechanism, as any one can see who is familiar with this class of machines, is quite simple. As the stamp drops, the tappet strikes a rod which communicates the necessary motion to the machine. A circular inclined table under the hopper is revolved slightly at each stroke, which action causes the ore to drop off the front of the table into the battery. Two iron flanges extending from the hopper to the revolving table as shown, serve to confine the ore in its place and to push it off. A "carrier" motion carrying the load forward is communicated to the ore and the feed is regular, no matter how the ore varies in character. Wet ore will go through as well as dry, and fine as well as coarse. A hand wheel regulates the lever so as to suit the feed required, and to compensate for the wear of the shoes and dies. In case the shoes and dies wear off half an inch or so it would give too much motion to the table, which can easily be regulated by the hand lever. The objections urged against the feeders mentioned above are overcome by the improved machine. The machine feeds twenty-four inches wide.

MINT WORK FOR NOVEMBER.—The following is an exhibit of the work done by the mint during the month of November: Gold coinage, 91,000 double eagles, value, $1,820,000. Silver coinage, 517,000 trade dollars, value, $517,000; 72,000 half dollars, value, $36,000; 2,500,000 dimes, value, $250,000. Total number of pieces, 3,180,000. Total value of silver pieces, $803,000; total value of gold pieces, $1,820,000. Total value of gold and silver pieces, $2,623,000.

THE practice of allowing a discount to those who promptly pay assessments has been inaugurated by some of the mining companies.

Death of the Hon. Benjamin P. Avery.

The death of Benjamin P. Avery, U. S. Minister to China, is announced by telegraph. The news was not unexpected by the many friends who knew the state of his health at the time he accepted the position he occupied. It was hoped that the change might be beneficial, but he had enfeebled his constitution by too close application to study and literary work, and the cares of office and effects of the climate have hastened his end. Mr. Avery was born in New York, but has passed the best part of his life in California, having come around the Horn in 1849. For a time he engaged in mining, and then he kept a drug store at North San Juan, Nevada county. Soon, however, he gave up this business, and in 1855 he published the San Juan *Press*, a journal which for several years he edited with marked ability, and made it one of the leading papers in the mining region. The Marysville *Appeal*, recognizing his talents, afterward engaged him on its editorial staff. In his literary labors at this period he was associated with Noah Brooks. In 1861 the Republican party put Avery on its ticket for State Printer, and he was elected. Two years subsequently he lost the nomination, and then became connected with the *Evening Bulletin*, first as Sacramento correspondent, then as city editor, and latterly and for about eight years as leader writer. One year in addition he passed at Washington as special correspondent. In 1873 he took a vacation of about three months, and in January, 1874, he was chosen editor of the *Overland Monthly*, to which in former years he had contributed many articles. His connection with the *Overland* lasted six months, and then, through Senator Sargent's influence, he obtained the appointment of Minister to China. Mr. Avery was noted as a careful, clever writer and an upright, honest man. His genial nature and pure character made him a host of friends, who mourn his loss. Mr. Avery was one of a few who have done much for art in this city. He was one of the founders of the Art Association and School of Design, aiding both with great enthusiasm. Mr. Avery was a representative Californian and one of whom his friends were proud. He was an industrious, painstaking writer, no matter what the character of the work in hand. In common with many old Californians we remember his work on the old *Hydraulic Press* in early days, and from then until his departure from our shores we have many pleasant causes of remembrance. His career is ended, but his name will live for many a year among the thousands of friends he drew to him by his noble, upright character and amiable disposition.

FATAL MINING ACCIDENT.—A fearful accident happened at the Eureka Consolidated mine, on Ruby hill, on the 27th ult. While the cage was being lowered down the mine, the reel shaft suddenly broke, precipitating the cage down to the seventh level. John McGinnis, a shift boss, was on the cage with some heavy timbers. He was instantly killed, his body being horribly mangled. When the cage struck the seventh level station, the timbers became loosened, were hurled down the shaft to the bottom, where two miners, named Hugh Holmes and Tom McConahan, were at work. Before being able to escape, both were struck by the falling timbers, and Holmes had both legs broken. McConahan received internal injuries, which will probably prove fatal.

A LOS ANGELES dispatch of the 28th says: At the San Fernando tunnel this morning, the boiler of the engine at shaft No. 27 exploded and instantly killed Edward McCarthy; Charley Every was badly, and probably fatally, injured, and C. McKenzie, James Keavy, John Joseph and Joseph Antoine were all badly scalded, but none are thought to be fatally injured. The Coroner's jury rendered a verdict to the effect that McCarthy's death was caused by an unavoidable accident.

THE Virginia and Truckee railroad company has purchased for a depot at Virginia all the ground lying between Union and Mill, D and E streets, and the erection of buildings for the passenger and freight traffic will soon be begun.

CORRESPONDENCE.

Bald Mountain Mining District.

MESSRS. EDITORS.—Noticing an article by Mr. Gibbs, in a July number of the PRESS, upon the mines of Bald mountain, White Pine county, in which the writer speaks in flattering terms of one or more mines in that district, I would ask the privilege to briefly describe a few silver mines in the district, and, if possible, convey a clear understanding relative to the same. Prominent among the lodes is the Crown Point, so called from the famous one on the Comstock. It is situated near the summit of a lofty range, connecting with the principal mountains of the neighborhood, in Bald mountain, White Pine county, fifty miles north of Hamilton, and from ten to twelve miles in an easterly direction from Cold creek. This mine crops out boldly near the summit. Its surface has a broad lateral extension of thirty feet. The lode is opened by an incline, driven a distance of forty feet in ore nearly all the way.

The present face of the incline is in quartz, more or less impregnated with carbonates and chlorides, though of a low grade; yet the prospects of this mine are of a very promising nature, and assays may be had ranging from $18 to $128 to the ton.

The vein indicates a true formal one, having a fine clay seam one or more inches in thickness, carrying a smooth and even surface, and more or less colored with the mineral constituents of the lode. The breadth of the vein in the tunnel has nowhere been determined, as standing masses of ore mostly form the western wall of the incline.

The vein has a north and south direction and also carries small bunches of silver antimony glance, generally found in a defined direction along the line of selvage.

Less than half a mile south from the Crown Point is the Sutro mine, outcropping from the face of a bluff of silurian limestone, and is itself, so far as opened (some forty feet), from one to six feet wide. The ore from this mine is mostly chloride, and specimens will assay from $50 to $500 per ton. Indeed, assay samples might be obtained, ranging up in the thousands. But this, like all rich veins, does not carry its chlorides in one continuous stretch, but more or less barren spaces have to be passed through before rich ore is obtained. The ore vein has greatly contracted near the face of the incline, but there is good reason to believe that it will be found to widen as further sunk upon. Ore has been shipped from this mine yielding $125 to the ton, and considering the shallow depth that it has been opened up, its value can hardly be said to have been sufficiently tested.

On the western slope of the same timbered range are the croppings of two other silver veins that have been prospected to some extent. One of these, the Argentic Sulphide, is a crevice from one inch to two feet wide, has a short incline in the side of the mountain of fifteen degrees. Two tons of ore have been extracted. The ore is mostly an argentiferous sulphuret of lead or black metal, assaying $75, $262 and $576 to the ton. Not far from this last mentioned vein, and still lower down the mountain, near where the country rock is somewhat metamorphic, there outcrops in a north and south direction a vein of quartz and ore from one inch to a foot in thickness and several hundred feet in length, cutting the somewhat decomposed limestone at nearly right angles. Near each end of this vein a shallow shaft has been sunk, showing a seam of rich chlorides and sulphurets assaying from $200 to $600 to the ton of 2,000 pounds.

Besides the above mentioned silver veins and in the same district, are several copper croppings, one or two showing large bodies of mainly copper carbonates, ranging from fifteen to forty per cent., and more or less argentiferous. The district is well supplied with wood, water and grass, and the property at the present time can be bought or leased upon very favorable terms. HARMON OLMSTEAD.

Eureka, Nev.

THE TWENTY CENT COINAGE.—There is considerable speculation concerning the reason why the new twenty cent coin does not get into more general circulation. An explanation is given, as follows: There is but one way in which the twenty cent pieces can be issued from the Mint, and that is in exchange for gold coin at par. This is the law in reference to all subsidiary silver coins, and the twenty cent pieces are no exception. The Mint has turned out $231,000 in twenty cent pieces to date, of which some $5,000 or $6,000 have been paid out in the institution, $22,000 remaining in hand, and the balance having been shipped East with other subsidiary silver coin in pursuance of the plan for the redemption of the fractional currency with small silver coins. The $22,000 on hand can be obtained by any one wanting it, in exchange for gold coin, and more will be made if desired, to supply any demands that may arise. If the twenty cent pieces are not in circulation it is because they were not applied for, and those who procure subsidiary silver coin for their business purposes do not desire this variety.

Report of the Director of the Mint.

The report of the Director of the Mint for the last fiscal year has been submitted to the Secretary of the Treasury, and shows in detail the operations of the mint and assay offices during the year. The coinage was: gold, 1,739,062 ounces, value, $33,053,965; silver, 22,723,216 ounces, value, $10,070,368. An extensive refinery has been erected and put in operation in the new mint at San Francisco, and the refining capacity at the assay office at New York has been largely increased. At the Philadelphia mint additional annealing furnaces have been constructed. The coining machinery at the Carson mint has been duplicated, and the mints are now all in a very efficient condition. In discussing the coinage of the trade dollar in connection with the substitution of subsidiary silver coin for fractional currency, the director shows that it can in no way interfere with the plan of redemption, its coinage not having the least effect upon the market value of silver, as shown by the average price paid for silver bullion. After the redemption of the fractional notes, silver coins, with the exception of the trade dollar, can be issued under the coinage law in exchange for gold coins at par. This limitation will be a barrier to their excessive coinage, and the demand for bullion for that purpose must, after two or three years, be quite small. The trade dollar has been well received in China, and the director thinks that if authority were given to coin at our Western mints smaller denominations of silver coins of the same standard, they would no doubt find a ready market at different ports, and gradually work their way into the interior of the Chinese empire. Under the provisions of the first section of the Act of January 14, 1875, the mints have purchased to the 31st of October last 9,183,417 ounces of

Silver Bullion,

At the average price of $1.11 4-10 per standard ounce. The average price in London has been at the rate of $1.12 4-10 per standard ounce—the coinage rate of the fractional silver coin being $1.24 4-10 per standard ounce. Since the first of February, 1875, the mints have coined $7,820,908 in fractional silver coin, and the treasury and mints held on that date $1,500,000. Adding to these amounts the coinage for November, which may be set down at $600,000, would give a total of fractional silver coin in the treasury and mints on the 1st of December next of $10,000,000. The director treats at some length on the policy of redeeming fractional notes in silver coin. The cost of maintaining the fractional currency during the past year was $14,107,462. This does not include the expense of handling it at the subtreasuries and depositories, which, if added, would probably show

The Total Expenses

To be equal to about five per cent. on the annual issue, and corresponding with the interest on the amount of bonds which may have to be sold to procure say thirty-six millions in gold, the value in silver bullion of which would give silver coin of the nominal value of forty-five million dollars. The total expense attending the manufacture of the coinage of the last fiscal year ($43,854,708) was $889,370, or about 60 per cent. of the expense of maintaining fractional silver currency. In this estimate the seignorage realized on the silver and minor coinage ($436,105) has not been considered as reducing the cost of the coinage, the same being regarded as a gain to the Government, and not an earning by the mints. The director suggests an increase in the legal tender of

The Trade Dollar

And fractional silver coins, from five to ten dollars. The financial measures adopted by Germany, France and other countries, and their bearing upon the money disturbances of the last three years, are carefully reviewed by the director, who states that whenever Germany shall have its great monetary reform fairly under way, and France sets free her immense specie receipts, the active demand for gold will no doubt cease the United States, and they may then safely undertake the acquisition of a sufficient stock of coin for the

Resumption of Specie Payments.

The extent of the falling off of silver is shown by the fact that the gold value of the principal legal tender coins of European countries has of late averaged about 8½ per cent. less than their nominal or total value in the moneys which they respectively represent. In speaking of the change in the relative values of gold and silver, the director states that no further distinction of exclusive gold standards appears to be probable for some time to come, and that an increased demand for silver may be reasonably expected, but not sufficient to cause a material alteration in the present valuation of gold and silver, which is about 1 to 17. Under the title of "Money and the Money System of the United States," the director states at length the general principles which govern monetary systems, the importance of maintaining a uniform

Standard of Values,

That all experience has proved the precious metals, and particularly gold, to be the least variable and the best adapted for a circulating medium of all known substances; the units of money of account of all countries, as assayed in modern civilization, were originally based on, and declared by law to be represented by a certain weight in metal in the form of coins, and by being so fixed became a basis of exchange and the measure of contracts. The discussion of many of the money systems for the United States soon after the adoption of the Federal Constitution and the passage of the Act of April 2, 1792—establishing gold and silver as the monetary standard—are referred to, and the statement made that no Act of Congress before that of February 15, 1862, made anything but the precious metals a legal tender. This is pronounced to have been a radical departure from the sound principles on which our money system was originally based, and could only be justified as a war measure in a time of imminent peril. The director concludes his observations under this head as follows:

A Forced Paper Currency

Is well known to be, from various causes, subject to frequent fluctuations in value, and, unlike the precious metals, is wanting in the property of self-adjustment under the operation of supply and demand, and for these reasons alone must always prove an uncertain system on which to conduct the business and exchanges of a country. The developments of the Comstock lode in the State of Nevada form a special subject, a careful examination of the Consolidated Virginia and California mines having been made by the director and Professor R. E. Rogers, of the University of Pennsylvania, in July and August last. The director estimates the annual product at $50,000,000 from the Comstock mines alone, about forty-five per cent. of which will be gold, and that a production nearly equal to that of the Comstock may be anticipated from other domestic sources during 1876. Professor Rogers, in his conclusion, and in which the director concurs, states that from much of the data obtained by the examination and on an inspection of official surveys, exhibiting galleries and crosscuts, it would seem fair to conclude that with proper allowances the ore to-day equals an amount which, taken at the actual assays, would give an ultimate yield from the two mines of

Three Hundred Millions of Dollars.

But to guard against a chance of over-estimation, take assays at one-half that which has been ascertained, which would place the production at not less than one hundred and fifty millions of dollars. In making these estimates Professor Rogers says: "With a view to making due allowance for interruptions to the continuity of the body of ore which lies between the 1500 and 1600-foot levels, the whole of the ore which is contained between the 1400 and its deeper levels is thrown in and not embraced in the estimates, and the very promising developments below the 1550-foot level, assays of which are very high, have been omitted in the calculation." The director, in concluding his report on the Comstock mines, says: "The favorable condition of the precious metal mining industry is due to judicious expenditures of

A Large Amount of Capital

In extensive enterprises by men of superior energy and business qualification. Nearly all the mines on the Comstock, as well as the hydraulic gravel mines in California, and mines in other localities, as a general rule, have made heavy drafts on labor and capital before any returns on the outlay were secured. Notwithstanding the improvements which have been made in mining and in the reduction of ores, the business is one of uncertainty and hazard; and taking one year with another the expenses no doubt equal, if they do not exceed, the production. Many of the present large yielding mines were originally discovered by adventurous and daring prospectors, who are always advancing into unexplored localities and enduring hardships and danger, which would soon discourage the boldest were it not that under the liberal and fostering policy of the Government discoveries which they make become their own property, subject to conditions looking to a certain degree of exploration and development before a complete title can be acquired.

The First Capital

Which follows these prospectors is generally sunk, and but a small proportion of the mines are continuously worked, many being totally abandoned after considerable expenditure has been made. These facts show that the policy pursued by the Government with reference to the precious metal mining interest has been eminently wise and should be continued." The director estimates the specie in the country on June 30th, 1875, at $167,614,803. The money system of China, Japan, coinage and several other articles of an important character are contained in the balance of the report. Dr. Linderman, Director of the Mint, will shortly begin the preparation of his report upon the location of the new United States mint, which it is proposed to locate somewhere in the Mississippi valley. Some of the competing cities have not yet sent the information called for. Those who have not complied with these regulations are requested to do so at once, so that their representations may have a place in the coming report, which will be made to the President.

POTATOES FOR EUROPE.—Europeans appear to entertain a most wholesome dread of the American potato disease, which is due to the ravages of an insect, called by the scientists *Crysomela decemlineata*, but which some of our farmers, for short, call 10-lineata. The German government has peremptorily forbidden their introduction into that country, under any present circumstances; while King Oscar, of Sweden, is willing to admit them if the potatoes are thoroughly washed, and the packages in which they are imported are submitted to a baptism of fire at the port of entry. The Colorado bug receives profound attention wherever he appears—confound it.

An Important Revelation.

An English journal pronounces the treaties lately negotiated by Mr. Burlingame between this and several European governments and that of China as mere shams. It claims that the embassy by which the treaties were executed and which accompanied Mr. Burlingame was a deliberately planned Chinese deception, of the knowledge of which, however, Mr. B. was ignorant.

The reason given for this conclusion is the assertion that the treaty was never published in the Peking *Gazette*, the official organ, and that the high functionaries of the empire are not bound by any treaty or law which has not been duly published therein. If the treaty was never so published it is quite clear that it is not acknowledged there; and yet that treaty is the only foundation upon which the relations of this country stand with China.

It is barely possible that English jealousy may have distorted the facts in the case; but the statement is one which should at all events be enquired into by our minister at Peking, and its truth or falsity set at rest.

The Chinese government is one which no one acquainted with its character will think incapable of such duplicity if means can be found for carrying it out.

Be the facts as they may, there appears to be good reason to believe that the English government give them credence, and this fact is given as the reason for the demand recently made by the British minister at Peking that the punishment of the murderer of Margery and all the other acts of reparation to England shall be inserted in the Peking *Gazette*, as an official recognition that such acts have been decreed by the government, and thus been established as precedents. This prompt and decisive action of the English government in establishing their rights under the treaty, by subsequent official recognition of the legality of its penalties, should prompt our own government to take some steps to learn definitely upon what footing our relations stand with that proud and slippery people.

The Future of Mariposa.

Our town of Mariposa, we repeat, is looking up once more. There are causes silently at work which will, at no distant day, bring back the ancient glories of Mariposa again. There is too much productiveness in our foothills and valleys, and in the hillsides themselves, to remain long uncultivated. And, we might add, there is too much gold in our immediate vicinity, obtainable with moderate labor, not to attract miners to unearth it. Right here at hand we have Missouri gulch, Specimen gulch, Mormon bar and various other places which have not as yet been more than fairly prospected, and which it is well known are rich with gold, not to say anything of the Fremont lode, at the foot of the town, on which the famous old mill stands, which has ground out its millions. Let any one take a ride over the ranch of our friend Snyder, the Pine Glen ranch belonging to John Mathews, and the Laird ranch, formerly owned by Skelton, and see what industry has done, and then look at the hundreds of other places contiguous to the town of Mariposa, which can be made just as valuable, and the conclusion cannot be resisted that from the increased flow of immigration into the State, we will eventually draw population within our boundaries to take up these lands and cultivate them. Among the causes alluded to, which will resuscitate our town, is the fact, there is too much good sense, too much enterprise, and too much money in the possession of the members of the Mariposa land and mining company not to perceive the immense benefits to result to their estate in this county by cutting a canal and introducing water along the divide which runs through it. The success of similar enterprises in the State has stimulated them to seriously consider the subject, and that they will move in the matter shortly cannot well be doubted. This company, whom so many look upon as destructive to the best interests of the county, may yet prove its salvation. When this great work, which has become a necessity, is commenced, then may we expect to see the iron horse snorting into our town to awaken our people from their lethargy. The subject has already been mooted, and a branch road connecting with the Southern Pacific, should not be treated with indifference. In truth, the outlook is favorable, and the probabilities are strong that real estate will shortly assume proportions and take an upward tendency.—*Mariposa Gazette.*

ENGINEERS OF THE SUTRO TUNNEL.—A question having arisen about the names of the engineers appointed by the President to examine and report on the Sutro tunnel, we have consulted one of the officers of the regular army, and learn that they were Lieutenant-Colonels H. G. Wright and John G. Foster, Corps of Engineers, U. S. A.; and Prof. Wesley Newcomb, of Ithaca, N. Y., a mining and civil engineer; Capt. W. R. King, Corps of Engineers, U. S. A., secretary of the commission.—*Alta.*

SHUT DOWN.—The Krom concentrating works at Galena have been stopped in consequence of the wet weather, and we see by the *Reveille* that the Manhattan works at Austin, which are of a similar character, are about to do likewise. In the Krom concentrator the ore is passed between rollers and through screens, and it cannot be treated by this process while wet or even damp.

SCIENTIFIC PROGRESS.

Proof that Electricity is not a Fluid.

An electric spark, however powerful, cannot be made to pass any distance, however small, through a perfect vacuum. It is retarded just in proportion to the nearness to which a vacuum is produced. The degree of perfection in a vacuum may thus be accurately measured. We possess, says the *Manufacturer and Builder*, a tube, in which the two platinum wires are only a quarter of an inch apart, but the vacuum is so perfect that the spark from a large Ruhmkorff coil, which in air passes easily over twelve inches space, and in rarefied air twelve feet, or perhaps any distance, can not be made to pass over the space of only a quarter of an inch of such a vacuum.

If proof were wanting of the non-existence of the so-called electric fluid, it is here; if electricity were indeed a subtle fluid it would pass easier through an absolute vacuum than through rarefied air; but the reverse is the case.

It behaves thus similar to sound, which can not be propagated through a vacuum, even if imperfect. This proves that sound progresses by a certain motion of the molecules of the medium which propagates it; and in the same way the experiment mentioned proves that the existence of an electric fluid is as apocryphical as that of a sonorous fluid would be, and that electricity is simply propagated by a certain motion of the molecules of the materials which we call electrical conductors, and is therefore merely a mode of motion—the same as heat is a mode of motion.

But for heat we have no experiment so directly proving its immateriality as the above experiment proves it for electricity. We are not yet able to make a vacuum so perfect that no caloric rays will traverse it; notwithstanding this, the idea of a caloric fluid has been abandoned by all advanced philosophers, and the theory considering heat as a mode of motion must be acknowledged to be established; how much more then are we entitled to consider electricity as a mode of motion, having succeeded in making a vacuum through which it cannot manifest its action.

Fruit in Prehistoric Times.—Carbonized apples of small size, identical with those growing wild in the woods of Switzerland, have been found abundantly in lake bottoms, and in a tolerable state of preservation. Mr. Messikommer discovered on one occasion more than three hundred of them lying close together. They are often cut in halves, more rarely in three or four parts, and were evidently dried for consumption during winter. Whether a larger kind of apple found at Robenhausen was cultivated, or a wild-growing species, remains undecided. Professor Oswald Heer, of Zurich, who has published an interesting work on lacustrine vegetable remains, inclines to the former view. Wild pears were treated in the same manner; but they are far less common than apples, which must have formed a much-sought article of diet. Among other vegetable remains accumulated in the lake mud may be mentioned hazel-nuts and beech-nuts, both in great plenty; also water chestnuts, which doubtless were collected and eaten by the lake-men, as they are in Upper Italy at this day. Their present occurrence in Switzerland appears to be restricted to a tarn in the canton of Lucerne. There have further been found abundantly the stones of sloes, bird cherries, and wild plums, and seeds of the raspberry, blackberry, and strawberry, showing that these fruits of the forest were used as food. According to Dr. Keller, the lake colonists of the Stone Age drew their sustenance chiefly from the vegetable kingdom. Their animal food evidently was acquired by hunting rather than by the breeding of cattle, considering that in the accumulations around the piles the bones of wild animals outnumber those of the domestic species. Milk, we may assume, formed an important article of their diet.

To Fix Magnetic Curves.—The following neat methods of fixing the beautiful curves made by iron filings on paper, under the influence of a magnet, are from an interesting article in the *Electrical News*, describing the practical instruction in electricity and magnetism at the South Kensington science school:

1. Make a solution of gall nuts. Brush over sheet of paper with solution; remove superfluous moisture by blotting paper. Place damp paper over curves, press evenly, carefully lift paper; dry quickly, and shake off filings. A permanent impression in ink will be left on the paper. 2. Fix pair of magnets to one side of square of glass, coat other side with very thin gum water; when plate is quite dry, dust fine iron filings over gummed surface, tap, then breathe gently on plate. Gum is thereby softened and curves fixed.

Nature of the Tails of Comets.—It is known that the iron-nickel meteorites often contain hydrogen in occluaion, but Wright has discovered by means of the spectroscope that the stony meteorites contain the oxids of carbon instead of the hydrogen, and it is given off at so low a temperature that it is often sufficient to mask the hydrogen. The amount of these gases, according to Wright, is sufficient to form the tail of a comet, while the spectrum of their tails corresponds, or rather is identical, with these gases.

Copper Pipe Electrified by Steam.—M. Donato Tomasi says, in a late number of *Comptes Rendus:* "When a current of steam is made to traverse, under a pressure of five to six atmospheres, a copper tube of two to three mm. diameter wound spirally around an iron cylinder, the latter becomes so strongly magnetic that an iron needle placed some centimetres away from the steam magnet is energetically attracted, and remains magnetized during the whole passage of the steam current through the tube." In continuation of this, M. Maumene, in the same journal, quotes the following observations: "The important experiment of M. Donato Tomasi should, it seems to me, be interpreted by a very different consideration from that of the author. Heat does not act so as to produce 'a new source of magnetism.' It produces a thermo-electric current, generating the observed magnetism, and is set up by the difference of temperature between the interior surface of the copper spiral traversed by the steam and the exterior surface exposed to the air. M. Tomasi ought to be able to reverse the current, and consequently the poles, by causing the heat to act so as to warm the exterior surfaces, at the same time maintaining the interior surfaces colder."—*Engineer.*

Molecules—Their Relation to Pressure.—Every substance is now supposed to be composed of an immense number of molecules, which, even in the solid state, are never entirely at rest, and, in the gaseous, are in a state of perpetual violent commotion, rushing about in straight lines in all directions with inconceivable rapidity; and it is this perpetual bombardment, as it has been called, by these little particles, that explains the known pressure of gas on the walls of any containing vessels, the incessant impact of the molecules producing the effect of one continual pressure, just as upon the eye a succession of rapid flashes of light have the effect of one continuous flame. Of course the molecules, although they are supposed to be separated for a very considerable distance from one another, are perpetually meeting and rebounding, and thus their velocity is interfered with, but there is a certain residuum of speed left, resulting in a mean velocity for the whole. This mean velocity indicates also temperature, and, for the same substance at one pressure, the same mean velocity is always accompanied by the same temperature.

Action of Plants on Impure Water.—At a recent meeting of the Societe Centrale d'Horticulture de France, Jeanuel related the following experiments with water containing putrid matter:— In the month of May, sixty grammes of water, which had been used for steeping haricots until it had become offensive, and which the microscope showed to be full of *bacteria*,—small animalculæ, supposed to be the ordinary agents of putrefaction,—was placed in a glass, and the root of a young growing plant plunged therein. An equal quantity of the same water was placed beside it in a test glass at the same time, without a root. The water in the second glass remained infected; that containing the living root, on the contrary, was pure at the end of the fourth day; all the *bacteria* had disappeared, and had been replaced by large infusorial animalculæ of kinds found only in potable water. Water containing putrid meat was treated in the same way, with the same results. It was found that it was only necessary to immerse the root of a living plant therein for five days, to remove all the ill odor and render the water pure and sweet.

The Limit to the Carburation of Iron.—Dr. Percy gives 4.4 per cent. as the maximum of carbon able to combine with iron. Karsten gave 5.1 per cent., stating that with this proportion a fixed compound was formed, represented by Fe_4C. The author could trace no decided difference in combined carbon between white and gray cast iron. The maximum he asserts to be 4.06 per cent., and that any surplus of carbon is in the form of graphite. If an iron containing this quantity solidifies quickly, it is homogeneous, and retains in the solid state the whole of the carbon, whereas, if cooled slowly, it is not homogeneous, there being combined and free carbon, and probably pure iron.

Hot Glass a Conductor of Electricity.—Mr. Whitehorn, of London, has discovered that glass, although a non-conductor at ordinary temperatures, becomes a good conductor at red-heat; even at 212° Fahr. it conducts some electricity; at 330° it conducts six times better, while at 570° it conducts forty times better than at 330°. It thus appears that solid and melted glass is very much like solid and melted ice in its relation to electricity; for cold, dry ice is almost or quite as perfect a non-conductor as cold, dry glass.

Professor F. E. Nipher suggests the following optical experiment: Observe a white cloud through a plate of red glass with one, and through green glass with the other eye. After some moments transfer both eyes to the red glass, opening and closing each eye alternately. The strengthening of the red color in the eye, fatigued by its complementary green, is very striking.

Faraday established the fact that gases are but the vapors of liquids possessing a very low boiling point.

MECHANICAL PROGRESS.

Vulcanized Fiber—A New Water-Tight Joint.

We have already made mention of a new and remarkable material which has been called "vulcanized fiber." The uses for this material have already become quite numerous, and a large company has been organized in New York for its manufacture, which is said to be already doing a large line of business. New uses for the material are constantly being developed. The latest novelty in this direction is a water-tight joint, which seems one of those simple improvements the value of which is apparent at a glance. This joint is described in the *American Artisan* as follows:

The nature of this vulcanized fiber is such that, while it is absolutely insoluble in hot or cold water, oil, alcohol, naphtha or ether, yet it expands by exposure to moisture. This property has been availed of in making this joint, which certainly accomplishes its object most effectually. The boards or planks are jointed with square edges, and at the same time grooved by a circular saw of proper thickness to any depth desired. In these grooves is inserted a tongue of hard rolled vulcanized fiber, and the boards are driven closely together. Should any water leak through the joints to the tongue of vulcanized fiber, it will cause it to expand, and peck the groove tightly, and thus arrest its further progress.

This use was discovered by Mr. E. Waters, of Troy, the celebrated paper boat builder, who has built a number of wooden skiffs in this manner, thereby dispensing with all calking, adding greatly to the strength and stiffness of the boats, and considerably reducing their weight. He asserts (after severe tests) that boats constructed in this way never leak a drop under any circumstances.

Should the boards shrink a considerable distance apart, yet so long as the tongue remains in both grooves, the joints will always be water-tight. Of course, these tongues can be made of any desired thickness and width, so as to adapt them to all kinds of structures.

It seems to us not easy to over-estimate the importance of this device, and the multiplicity of uses to which it can be applied. In addition to small boats, it will be valuable in ship-building for ceilings, bulkheads, decks, etc., and particularly for deckhouses and the light upper works of steamboats. On railroads it will be used for car roofs, water tanks and stations; and for refrigerating cars, which require to be air tight, it will be invaluable. A prominent physician has suggested that if the ceilings, walls and floors of hospitals were constructed in this manner, it would admit of their being thoroughly washed down with hose every day or two, and thus keep them perfectly free from virus, and greatly improve their sanitary condition. Even in private dwellings and business warehouses, if the floors were laid in this manner it would obviate all damage to ceilings from bursting water pipes, or faucets left running; and, in case of fire, would restrict the damage by water to one story.

We are informed that to render all the floors of a first-class four story dwelling absolutely water-proof, in this manner, would not add more than from $125 to $150 to the cost of the house.

By reference to our May number, it will be observed that we spoke of journal bearings, gibs, powder press plates, valves, etc., made by this company. In addition to these articles, they are now producing a very excellent sheet packing, which for many purposes is far superior to rubber, and sold for less money. For either hot or cold water, petroleum, oil, turpentine, etc., it is claimed to be better than anything in the market, and sales for this purpose are stated to be large.

The "elastic fish bolt washers," and "oar box washers," or "back straps" made of this material, are now regularly used on thirty or more of the principal railroads. The works of this company are at Wilmington, Delaware.

Superheated Steam in Common Engines.—In Rounebeck, Bremen, an engine has been nearly completed by Herr Trossin which, it is thought, will solve the problem, which for nearly thirty years has engaged the attention of inventors, of the utilization of superheated steam in common engines. The answer to the problem has been found in the new application of a physical law, and the use of a peculiar lubricant. An engine working with superheated steam needs only half the ordinary amount of coal, the boiler and grate can be smaller by one-half, the supply of water by one-third, and the air-pump and condenser are equally reduced to half their usual space. The improvement has been patented in England, Belgium and other countries, and can easily be applied to engines of the existing type.

Steel Wire Rope.—Steel wire rope has replaced iron wire rope with advantage in several collieries in Prussia, particularly in Westphalia. In all the pits, however, it has been found that cast steel rope must be lubricated at least once a week, and laid on one side on the least appearance of fraying. At the Saarbruck collieries the experience of other places was repeated, that steel rope could be need of a smaller strength than iron, but required a greater drum cylinder.

The Demagnetization of Watches.

We have already alluded to the trouble often occasioned by the magnetization of watches, and we now clip from the last number of *Scribner's Magazine* a simple method for demagnetizing these indispensable pocket companions:

"Watches worn by students and others in technical laboratories are often rendered useless by being magnetized by the magnets used in such places. Magnets kept in the house often create equal mischief by being laid near watches, and much time and expense are sometimes needed to demagnetize them before they can be made to work. A serious case of this kind of injury recently led Professor A. M. Mayer, of the Stevens' Institute of Technology, Hoboken, to experiments which resulted in a very simple method of demagnetization. The magnetized watch was laid upon a table in the neighborhood of a common compass needle. Each hour on the face was then placed in turn before it to discover the location and intensity of the magnetism in the watch. The movement of the compass showed the north and south pole to be located (say) at the figures V and XI, while the neutral points were at VIII and II. The watch was then held in a horizontal position before a large bar magnet, the south pole of each being together. A gentle tilting motion was given to it for some moments, and, on trying the watch again before the compass, a sensible decrease of magnetism was observed. The process was repeated till the sensitiveness of the watch at that pole was nearly extinguished, when the same thing was tried with the north pole of the watch. After a few trials and comparisons, the magnetic influence was found to be removed, and the watch readily resumed its work."

Car Building for the World.—John Stephenson, whose name is seen on so many of our cars in this State, is the great street car builder of the world. A late visitor at his shops in New York speaks of him thus: He is now over sixty; as hale and vigorous as when he was thirty; under-sized, stocky, robust and cheery; a mechanic of the James Harper school. He makes cars for the world. No nation can compete with or undersell him. While I was talking with him he was making a contract for cars for Bombay. Twelve cars were ready for Liverpool. Others were on the wagon for London. Another lot are for Australia, Norway, Austria, St. Petersburg, and also America, and over our boundless Continent. Liverpool cars are double deckers; but Americans won't ride in them. All English care have the windows fastened down, and they can't be sold unless they are. These cars the English cannot make, though they have had the pattern for a number of years. Nor can that wonderful nation make a rubber car spring. All are made here. Mr. Stephenson ships no cars. He delivers all his work in New York. Each nation, company, or man who trades for a car pays for it in New York. No contract is taken unless the contractor has a hanker in New York who will pay for the car when it is done. Mr. S. builds nine cars a week. He can take an order and have a car ready to ship in four days. Each car costs $1,000, gold.

A Substitute for Hydraulic Lime.—Zeiodelite is a comparatively new material, which has latterally come largely into use in France, as a substitute for hydraulic lime. It is said to be much superior to that material for uniting stone and resisting the action of water. It is made by mixing together sulphur and pulverized stoneware and glass, in the proportion of nineteen pounds of the former to forty-two of the latter. The mixture is exposed to gentle heat, which melts the sulphur, and then the mass is stirred until it becomes thoroughly homogeneous, when it is run into suitable moulds, and allowed to cool. This preparation is proof against acids in general, whatever their degree of concentration, and will last an infinite time. It melts at about one hundred and twenty degrees Cen., and may be re-employed without loss of any of its qualities, whenever it is desirable to change the form of an apparatus, by melting at a general heat, and operating as with asphalte. At one hundred and ten degrees it becomes as hard as stone, and therefore preserves its solidity in boiling water. Slabs of zeiodelite may be joined by introducing between some of them paste heated to two hundred degrees, which will melt the edges of the slabs, and when the whole becomes cold it will present one uniform piece.

The English Eighty-one-ton Gun to be Eclipsed.—According to the *Kolnische Zeitung*, Krupp is making preparations for the construction of a 124-ton cannon. This enormous gun will throw steel bolts weighing more than 2,200 pounds each, and will require a load of powder weighing 400 pounds. It is estimated that the projectile will pierce at a distance of 3,200 feet the heaviest plates, of 23.8 inches thickness, now used on the English ironclads, and that its extreme range will exceed seven miles and a half.

American Small Arms.—The Sharps rifle company, of Hartford, is experimenting with a new rifle which can be fired three times in a second.

Mining Stocks.

The stock market hss been "booming" this week, and Californis street is again in an excited condition. The prominent stocks on the Comstock show the greatest rise, very few of the acknowledged "wildcats", having followed enit as yet. Ophir, Consolidated Virginia, Ssvage, Chollar, California and a few others have made some pretty good npward flights, slthough fluctnations have been rather frequent. The scenes in the Board and on the street look like old times again after the long depression, and the hrokers are jnbilant over the rush of bnsiness. How long the "rise" will keep np, of course no one can tell, hut the general impression is that it is the long postponed "fall rise." Last August everything looked promising for a fine msrket; but the unforeseen events that snbseqently arose, seemed as though they would deter it for an indefinite time; and so they would almost any other branch of bnsiness bnt mining stocks. Stocks possess such a wonderful elasticity, that they are now, to-day, in a little over three months from the time when the first terrihle reverse csme, in nearly as good a position as they were in the middle of Angust. The depression in prices has been continned so long that it gave a color of truth to the ststements usually made when the market is down "that it will never go up again." This happens over and over again, however. The fluctuations give no evidence of a declining market, as it is always a psrt of the progrsmme to loosen the thnmb screws in an npward movement to catch the short interest; however, prices may go lower still before a permanent rise is sustained. Our stock tables show the fluctuations from day to day, which will show how the market has varied.

How Prudence Saved Life.—A letter from Wilkesharre, Pa., states that the most extensive and serious mining casualty ever known iu Wyoming valley occnrred at the Channcey and Grand Tunnel mines, between Plymouth and Nanticoke, about two and a half miles south of the former place. About two weeks ago Mr. Roberts, one of the proprietors of the Chauncey mine, noticed that the roof of the opening was working in a most extraordinary manner, aud was convinced that the mine was doomed to a certain calamity. Ahout 11 o'clock on the morning of the 10th inst. he gave orders for the men to leave the mine as scon as possible, and remove as much of the company's property as conld he taken ont. On the spur of the moment, the miners, to the nnmber of 125, left at 12 o'clock, taking with them the implements of their calling, and two hours later the mine caved in. The effects of the cave were terrific. Huge houlders were thrown ont of the mouth of the tunnel by compressed air, as if they had been pebhles, and the shock of the crash was like an esrthquske.

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in the Mining and Scientific Press and other S. F. Journals.]

Mining Summary.

The following is mostly condsnsed from journals published in the interior,in proximity to the mines meotioned.

California.

BUTTE.

Good Claims.—Oroville *Mercury*, Nov. 26: We met upon the street J. M. Frost, of Wyandotte, who has heen stopping the past summer up above Stawberry valley. He informed ns that some of the richest mines in the country are to be fonnd on or near the line between Ynba and Butte. Attention hss been turned in that direction recently, aud work enough done to warrant the ahove sssertion. He gave ns something of a description of some of the claims, from which we can come to no other conclnsion than that that place will be as mnch sought after as the rich gold fields of Cherokee.

Mining.—An abundance of water is now had at the claim of W. C. Hendricks & Co., in Morris ravine, and the earth is washed away very rapidly. Every spot of the hedrock that is left hare is snre to he covered with cosrse pieces of gold, that are enough to do one's soul good to look at. The only difficulty with the claim is that a portion of the hill npon the right hand slides down as fast as worked away, and therefore it requires a great deal of work to olear off a small spsce. But after a good run the golden shower that seems to have fallen upon the hedrock amply pays for the labor expended.

A Double Canal for Mining Tailings.—Marysville *Appeal*, Nov. 20: The Spring Valley mining company, at Cherokee, Bntte county, hsve just completed an extensive enterprise which is expected to relieve the oompany from annoying lsw snits for dsmage to lands below. Lsst spring work was commenced on the canal, which is 400 feet in width, with double channels, each abont 30 feet in width and about 350 feet apart, with emhankment approximating abont five feet in hight on the outside, with a fall of about fonr feet to the mile. The compsny have expended ahont $400,000 in obtaining right of way. Through this osnal or canals the compauy expect to rnn their tailings into the tules on the Sacramento, striking a point not far above the North bnttes. This enterprise was designed by Messrs. Moore & Morgan, of the company, though snbseqnently modified by N. A. Hsrris, engineer of the company, with the assistance of engineer T. W. Reece, of this oity, who hss given the matter some considerable attention. The enterprise is expected to prove successful, and a precedent for other mining companies. The contract was taken by Mr. Bullsrd and Bsyliss Bros., of Bntte county, and the work has been most satisfactorily performed, giving employment to 200 men with steam horse scrapers, which were worked night and day. The canal is to be extended.

EL DORADO.

New Mill.—El Dorado *Republican*, Nov. 25: Work on the new mills and hoisting works on the Chnrch Union mine, nnder the snperintendence of Dan. Wickham, is progressiug fsvorably. There are now two shafts down 300 feet each on this property, and good pay rock hss been taken from both. We saw a speoimen from one of these on Mondsy that was exceedingly rich. With the new and improved machinery now heiug pnt on it we have every reason to helieve that it will soon rank with the best of our mines.

INYO.

Coso.—Coso *Mining News*, Nov. 25: Good progress has been msde in all the workings of the Defiance mine, and the yield of ore has been abont eqnal to the amonnt removed by the ore teams, which have been hsnling constantly. The winze in the sonth drift is now down sixty feet in good ore of soft grey carhonstes, the extent of which is not known, ss

the only effort being made is to attain depth, and no cross-cutting has yet been attempted at this point. The south drift is now in 130 feet and is yielding large quantities of first-class ore, the character of which is grey carbonate, imbedding large kidneys of rich galena. The upraise at the termination of the main tunnel has reached a distance of fifty feet from the starting point, and is being pushed rapidly to the surface for air and ventilation. It has passed through the ledge walls and is not now yielding ore. The north drift is still in good ore, and the yield from every point in the mine is satisfactory in the extreme. About fifty tons of ore are now daily being hauled to the furnace, so that when ready to start a good supply will have accumulated. The strike in the Bella Union, one of the Coso Consolidated mines, is described as follows: At a point in the 120-ft level, running east 20 feet from the main incline, the vein was cross-cut to explore the ore body at that point, and at this writing it is found to be from 15 to 18 feet in width, without yet reaching the hanging wall. The ore is of the richest character yet found in this mine, the assays running over $300 per ton, and the extent of the ore body not yet fully ascertained. From the cross-cut drifts are now being run east and west, and have progressed each way for a distance of about 15 feet, and the face of each is in the same extra quality of ore. From this opening about 16 tons of rich ore is being raised daily and wheeled on to the ore dumps without any assorting, as every ounce of it contains the richest carbonates and galena mingled. The main east drift has now reached a point 150 feet east from the main incline on the 120-ft level, and continues in ore, as it has all the way from the cross-cut 120 feet back of it.

MONO.

Benton Mines.—Cor. Inyo *Independent*, Nov. 20: Mill and mining matters are, if any difference, progressing. The mines of the Indian Queen mill and mining company have gained a place in the front rank of mining property, and the company has already more than paid the original cost price out of the proceeds of this summer's run. Mr. Mack's mill and mine, (the Camanche) are scaling the barricade of debt, and bringing the proprietor out beyond the reach of Old Obligation to any man. A. B. Williams' mill and mine are just now under attachment and injunction for the non-payment of old security debts. But we still believe he will dissolve these injunctions, and yet produce many "Benton hits."

NEVADA.

Important Discovery.—Nevada *Transcript*, Nov. 27: A company composed of Peter Johnston, Frank Beatty, D. Wellington and others, have for a long time been running a tunnel into the ridge on the south side of Deer creek, out near Hughes' ranch, with a view to strike an ancient river channel, which it was conjectured ran through there. There have been indications of striking gravel for some time, as we some months ago stated. A few days since the perseverance of the company was rewarded by striking the lead. At last they have found gravel, and it prospects first-rate. It is said the gold can be seen all through the dirt. Some think the channel follows the ridge, but others think the old Coyote lead, which was so rich until worked out, extends in the direction of the present find; but Deer creek, or some other cause, cut out the break between the two points. At all events the discovery is a very important one and created considerable excitement here when known. It opens up another mining field close to town, and from what we can learn it will be a very rich one. We congratulate the company on their very good luck.

PLUMAS.

Gopher Hill.—Plumas *National*, Nov. 20: The heavy rain started the water through the Plumas mining company's ditch, and the big pipes are now tearing down the gravel. Mr. D. Folsom informs us that they commenced piping on Wednesday, running 1,700 inches of water. The lake at the head of the ditch is filled to the extent that they can safely count on thirty days' run, unless a heavy fall of snow should close up the ditch. The company expect the ground now being piped to pay $500 per day. They are splendidly fixed for work, and will make "heaps of money" this year.

The Storm.—The rain storm which commenced on Sunday lasted almost without intermission until Thursday night, and was the heaviest storm that has occurred in this vicinity for years. It was accompanied by a strong, and at times a violent wind. The snowfall has been comparatively light, not over two feet of snow having been deposited on the higher mountains, and unless more falls soon, the roads will not be permanently closed. The rain has been a glorious thing for the miners, as it has thoroughly saturated the ground, and prepared it for the heavy snows which are sure to come later in the season. The prospects ahead for the miners were never more flattering, and the indications are that good times are coming.

TUOLUMNE.

The Confidence.—*Union Democrat*, Nov. 20: This mine is turning out ore sufficient to employ the crushing power of twenty stamps. The increase of rock will in a short time probably necessitate the running of the remaining stamps, 20 in number.

Gold Hunters.—Amateur prospectors will probably range the gulches and ravines tomorrow in search of nuggets, provided of course that the weather is fair.

Track in Order. — The track from the Spring Gulch mine to the mill is in running order and the work of crushing will probably be commenced in a few days.

Drifting.—In the Lady Washington mine the work of drifting from the shaft north and south still progresses and the rock encountered is of a fine quality.

Waiting for Water.—At the Soulsbyville mine hoisting works only are running, a lack of water preventing the running of the mill. The rains, however, will obviate this difficulty.

About to Clean Up.—At the Grizzly mine near Summerville the mill is still running, as they have a small amount of ore to crush before cleaning up. The batteries look well and there is every prospect of a most satisfactory result.

Nevada.

WASHOE DISTRICT.

Belcher.—Gold Hill *News*, Nov. 24: Daily yield, 420 tons of ore. This ore is being sent to the mills for reduction just as fast as it reaches the surface, and is of much better milling quality than for some time past. The ore breasts are looking finely, and the upper levels of the mine are yet far from exhausted of their rich ores. The water is steadily held at a point in the main incline below the 1600-ft station, so as to permit of the driving ahead of the prospecting drifts on the 1600-ft level. Everything in and about the mine is working finely, and the prospects of the Belcher are evidently looking up.

South Comstock.—Face of cross-cut still in very favorable vein matter, and something better should be met with before long. No water to trouble. Thus far the developments at this level simply go to show that all the company has to do is to sink deeper in order to find a good paying ore-body where the ledge is more concentrated.

Globe Consolidated.—At the third station level the drifts both north and south are in very promising ledge matter, the ledge at that point showing wide and the quartz being of an excellent character. Nothing new of other portions of the mine.

Consolidated Virginia.—The lower levels of the mine are kept in good repair, and a few tons of ore are hoisted daily through the Gould & Curry shaft. The C. & C. shaft is going steadily downward at the rate of 4 ft per day. The rock in the bottom works well, and the water has given no trouble whatever since the new pump was started up. It is now down 865 ft. If the good weather holds for a few days longer, the Consolidated Virginia will soon be able to begin hoisting her rich ores as usual.

Lady Bryan.—Sinking the main shaft is making good progress. Sinking the winze below cross-cut No. 5 on the 250-ft level is making excellent headway. This is intended for an air winze, and will greatly assist when completed the working of the south portion of the mine. Two cross-cuts are being run on the ledge, one east and the other west, at a point in the south drift 380 ft south of the shaft. Both of these cross-cuts are in very favorable quartz.

Julia.—Sinking the main shaft is making splendid progress; the bottom is soft ledge material, quartz and porphyry. The main south-west drift on the 1400-ft level is steadily advancing, the face showing very encouraging prospects.

Imperial-Empire.—Daily yield, 50 tons of ore, the average assays of which range from $50 to $65 per ton. The ore bressts on the 1900 ft level are gradually widening out and promise a much more extensive body and better yield than was expected when the opening of the level was commenced.

Bullion.—The north drift on the 2000-ft level is steadily advancing. The north drift on the 1700-ft level is going steadily forward, following the west wall of the ledge, the face in quartz and ore of a very promising character.

Sierra Nevada.—The north and south prospecting drifts, on the 700-ft level of the old shaft, are steadily advancing without any important changes to record.

Leviathan.—The cross-cut west, at the 420-ft level, is discontinued, having reached what is thought likely to be the west wall of the ledge. The ore-body is shown to be about 40 ft wide, and the face of the main drift north still continues in good ore, showing that its extent in that direction is not yet defined.

North Consolidated Virginia.—Occasional streaks of quartz and soft ledge material pitching steadily to the eastward, are encountered in the shaft, indicating that the main ore vein is not far away, and that when drifting is commenced there will be no great distance to run to strike the ledge.

Amazon and Glasgow.—The north drift on the second station level is in a distance of 46 ft, the face of the drift in fine looking quartz. The south drift on the same level is in 25 ft, the ore giving good assays, and the vein looks strong and promising. There evidently is a strong improvement over that of the ore vein on the level above.

California.—Sinking the winze below the 1550-ft level is going steadily forward, the bottom still in good ore. The face of the north drift on the same level is also still in fair ore. The frame of the battery mill is up, and is being covered as rapidly as possible.

Lady Washington.—The prospects for soon striking the main ore vein are growing more favorable every day. The flow of water is considerable, but gives no trouble, as the new pumping machinery handles it with the most perfect ease.

New York Consolidated.—Drifting at the 800-ft level, near the bottom of the shaft, is commenced. The material is porphyry, clay and quartz of the most promising character. The new machinery works well, and what water flows in at the bottom of the shaft is easily handled.

Dayton.—Sinking the shaft was suspended four or five days ago, in order to put in a tank station and another lift-pump, at the depth of 540 ft in the shaft.

Chollar-Potosi.—Daily yield 60 tons of ore, the assay value of which is $27 per ton. No change in the appearance or yield of the old ore producing sections of the mine.

Sullivan. — Tunnel still advancing at a lively rate in splendid looking ledge matter, showing streaks of low grade ore. When the proposed steam hoisting machinery is erected, the company will go in for seeking deeper.

Gould & Curry.—The repairs to the balance bob, which was broken last week, were but little more than completed, before a section of the pump rod parted in the shaft, creating still further delay and trouble.

Silver Hill.—The connection between the up-raise from the 4th station level and the winze below the 3d, is completed, which will greatly benefit the ventilation of that portion of the mine.

Savage.—The pumps are kept steadily at work draining the water from the 2200-ft level, with every prospect of soon getting the flow well under control. The machinery works well and every effort is being used to get the water down so as to resume prospecting at the very earliest moment possible.

Overman.—The south drift on the 900-ft level is steadily advancing, at the rate of 4 ft per day.

Leo.—Steady headway is being made in both drift and cross-cut. The face of the main drift is still in ledge matter of good character, and the material in the face of the cross-cut is improving in quality.

Woodville Consolidated.—The erection of the pumping machinery is making favorable progress, the woodwork being completed and most of the machinery in place.

Justice.—Drifting and cross-cutting at the 600-ft level is going ahead as usual, with plenty of good pay ore in sight and being shipped to the mill for reduction.

Original Gold Hill.—North drift running in low grade ore, with improvement in both quality and quantity, the last day or two. The south ore body is getting developed into good working shape, and the extraction of ore for milling will be commenced shortly.

Yellow Jacket.—The work in the drifts on the 1940-ft level has been delayed for the past 3 or 4 days by a breakage of some of the pumping gear.

North Carson.—Milling ore from the upper workings, the results of which will be good, judging from the excellent average assays obtained.

Florida.—Work in west drift progressing well, with very favorable indications of a good ore body being found when the main portion of the ledge is intersected.

Rock Island.—The ore vein on the 650-ft level is opening up more favorably as the drifts advance to the southward.

Nevada.—The winze from the east cross-cut shows improvement, the grade of the ore being higher, and the general body of it being stronger and better defined.

Hale & Norcross.—About 100 ft of the shaft is retimbered, and the remaining portion is being pressed to completion as fast as the work can be accomplished.

Cosmopolitan.—Lively prospecting going on at the various favorable points, with good results.

Utah.—The erection of the new hoisting works and machinery is making steady headway.

West Belcher.—Drifting north, following the ledge, and preparing to take out pay ore for milling, when connection with the old incline shall be made.

Sutro Tunnel.—Face of header in hard rock, but the Burleigh drills make good headway in it. Total length of tunnel last evening, 11,556 ft.

Crown Point.—Daily yield, 300 tons of ore. There is little or no change in any portion of the mine. Work is progressing well at all points.

Best & Belcher.—Owing to the delays of the Gould & Curry pumps, nothing is being done in the mine below the 1500-ft level.

Arizona.

Mining Affairs.—*Arizona Citizen*, Nov. 20: Messrs. Silverberg and D. A. Bennett returned the other day from the Patagonia mountains, whither they had been to inspect the mining property hitherto worked by Messrs. Fish & Bennett. Mr. B. informs us that Mr. Silverberg is much pleased with the mine, and, like all others who examine it, believes it a very valuable property. We expect to soon announce definite arrangements for extensive and improved reduction works on it.

During the week six thousand five hundred pounds of very rich silver ore was received here by Governor Safford and associates from their mine in the Pinal mountains. The ore is sacked awaiting transportation to Yuma, and thence to San Francisco. Careful assays show the lot to be worth an average of over $900 per ton, and one chunk of 300 pounds is believed to be worth $300. Many pieces of the ore show metallic silver. Arrangements are made for continuous shipment of ore. One interest was some time ago sold for $5,000 cash and another for several thousand, and in both cases the sales were made to enlist men of means and experience, rather than to part with the property. The Governor feels that he now has a prospect of getting a "funeral stake" without ceasing to divide up his salary with the thousand and one who almost daily insist on a part of it. This will be such good news to his thousands of warm friends, that we cannot refrain from giving it publicity.

Work still goes ahead on the "Old mine," Ostrich lode and mill, as well as other mining property.

Supt. Schemerhorn, of the Salero company, was in town lately and purchased and took out supplies, including an outfit for a blacksmith shop. He is developing the extent of some of the company's claims in a sensible way, and says machinery will be procured when he finds paying ore in quantities to justify the erection of works.

L. M. Jacobs & Co. have this week purchased $800 in gold; Wood Bros., 14 ounces; Zeckendorf's, 56 ounces; E. N. Fish & Co. $300, and other firms smaller lots.

Idaho.

The Owyhee Mines.—Idaho *Statesman*, Nov. 23: We had a long talk with Mr. Simon Harris, of Fairview, Owyhee county, about the mines and mining operations in Owyhee. Between 500 and 600 men have worked in the mines during the summer, up to about the 1st of October. Since then several of the mines have shut down, and the force at the present time is between 200 and 300. This force will be employed all winter. Since the Oro Fino mine started up it has seemed to bear the palm over all the other mines. The mine is under the superintendency of Mr. J. Catlow, who is working 100 men, and keeps 3 mills running, or in other words, 50 stamps. This mine will run all winter.

The Golden Chariot and Minnesota mines and companies have been consolidated, and they are now putting up new hoisting works of the most substantial character. They work about 20 men, but are not working any in the mine. They expect to get their new machinery running about the 1st of December. They will increase their force and work 30 or 40 men this winter. This is considered one of the best mines in the camp. This company paid their men for 2 months, last Saturday, up to the 1st of this month.

The South Chariot is working about 40 men; will probably work all winter; their men are also paid up. Mr. James I. Crutcher is the superintendent; he is also superintendent of the Panper mine. This mine has shut down, but they are pumping the water out. They have worked about 25 men the past summer, and are 2 months behind on their pay.

The Poorman mine is working about a dozen men. They had to suspend awhile, but have paid off one month in cash and one month in 30-day checks. The checks are bank checks and pass readily in paying debts or for goods. They have a good body of ore in this mine; and ought to go ahead successfully. D. Hoyt is the superintendent.

The Empire mine is running about 20 men. Russ Carter is the superintendent. Have not crushed much ore for some time back. Have been behind, but have recently paid off with checks.

The Mahogany mine has worked about 100 men the past summer. They have had to shut down, and are 3 months behind on their pay roll; but are keeping the water pumped out of the mine.

The War Eagle mine has shut down; worked from 15 to 40 men the past summer, and are 3 months behind on their pay roll.

The Ida Elmore is shut down; worked about 35 men last summer, and owe 2 months' wages to the miners.

Montana.

Montana Gold.—Helena *Independent*, Nov. 18: Since the first of last May the First National bank and L. H. Hershfeld & Bro., of Helena, have shipped East, in bullion and gold dust, two million dollars, the product of the summer mining. This gratifying exhibit in the production of precious metals will be additionally enhanced when the statement is made that it is nearly all from surface mining, and taken from mines immediately around and adjacent to Helena. With improved machinery and larger capital invested in the enterprise, this county alone could furnish six millions of gold annually to the coinage of the country. Indeed, there is scarcely a mining district in Montana but what can do as well under circumstances at all favorable to mining operations. With such a showing as this, Montana has no need to dread the rivalry of other sections. The day is not far distant when it will be the greatest gold producing country in the United States. All that we need is population and ordinary facilities for the development of our wealth.

Lucky Find.—A miner named Miller, near Butte City, is reported to have found in an ordinary gravel rock a specimen of surface gold worth $2,800. The rock, which has the appearance of an ordinary boulder, is literally seamed with gold. It had been laying on the ground near the gulch where a number of men had been working all summer, and had attracted no attention until accident threw it in the way of Mr. Miller, who casually picked it up, and found that he had come into possession of a golden bonanza. The gold is of the finest quality, and there is strong proba-

(Continued on Page 364.)

Geology of the Black Hills.

In the following extract will be found the most interesting portion of Professor Jenny's report as telegraphed to the Chicago *Inter-Ocean:*

That portion of the hills which is designated aa Harney'e Peak gold field ia almost wholly in Dakota and extends about fifty milea north and south, with an average breadth of nearly twenty miles, covering an area of not less than 800 equare miles. The valuable gold deposits, however, are found in the valleys of the streams which drain that area, the gold being derived from the disintegration of the quartz ledges, which are very numerous in the rocks of that region.

The most extensive and valnable deposits of auriferous gravel discovered during the paet seeson were in the valleys of Spring and Rapid creeks and in their tributaries, where in almost every case the gravel bars are very advantageously situated for working and many natural circumetances contribnte materially to the profitable extracting of the gold which they contain.

Timber of suitable size and quantity for the construction of flumea and sluices is abundant. The water supply is in most localities ample, and the fall of the streams sufficiently great to enable the watsr to be readily carried above the level of even the more elevated bars and deposited gravel.

While aa yet there have been discovered in the Black hills no deposits of gravel sufficiently rich to be profitably worked in the primitive manner with pan or rocker; yet there are many bars in the Harney Peak field, especially npon Spring creek, tho forks of Castle and Rapid creeks, and the valleys of those mountain streama, which, when skillfully worked by gangs of miners with sluices, will yield a good return for the labor employed and the moderate capital required to be invested. But little could be done in a single season in prospecting the numerous aggregated quartz veins of this region, some of which undoubtedly contain gold. I have procured abundent samples by testing their value by assay.

The Bear Lodge gold field, situated in the extreme northwestern portion of the hills, is wholly in Wyoming and entirely separated from the Harney Peak region. It does not exceed fifty square miles in area; the gold deposits are small compared with those on Rapid creek, and are remarkable for the absence of quartz in the gravel, the gold being derived from the disintegration of feldspar, porphyry carrying regular massee of iron, and manganese ore.

It is difficult to determine the agricultural resources or climate of the Black hills by the observation of a single season, especially as I could gain but little information concerning the severity of the winters or the prevalence of early and late frosts. The Black hills rise like an island from an ocean of grass covered and treeless plains, watered by occasional and ecanty snpphes of rain, and the winds in passing over these plains gather some moisture, which they part with as rain, being chilled by contact with the colder and more elevated region of the central portione of the hills. The reeult of thia is the prevalence of frequent though not heavy rainfalls, giving to the hills a most beautiful climate. There is scarcely a day from May to August without one or two showers, yet owing to the dryness of the atmosphere the climate is bound to be very healthy. During the past season after August 1st, very little rain was experienced, and some of the smaller streame contained water only in pools. That this is a remarkable rainfall, in a region where the average fall does not exceed ten inches for the whole year, does not appear, but I can only judge by observation on the growth of the plants and treea.

The abundance of the trees and the coarseness of their grain, as well aa their growth of plants on dry hill sides exposed to both sun and wind, tend to show that the season which I witnessed was by no means a very anomalous one, though the amount of rain may have been somewhat greater than usual.

The area of land suitable for cultivation from the mountainous character of the region ia limited as compared to the vast area embraced in the hills, but the soil along the streams and in most of the valleys is deep and fertile, and will be sufficient for the requirements of the popnlation which the hills will support as a stook raisiug community. I should say, from the observationa I have had the opportunity to make, that at least one-twentieth of the 3,000 sqnare miles embraced in the Black hills may be fairly described aa arable lands, and that near these lands lying near the streams and continuing through the hilly country are large tracts of land forming the surface of the hill eides which, whilo not arable, will afford fine grazing, largely enhancing the lands to which they are contignous.

Among the rocky areaa of the Harney'e Peak range and in the uorthern portion of the hills there are regions where the grassea are comparatively wanting, but geuerally throughout the whole area of the hills a luxuriant growth of the fineat grassea ia to be found, even covering the ground under the ahade of the pine trees upon the elevated divides between the streams.

The abundance and fine qnality of the grasaes, and the shelter afforded to stock by the deusely timbered slope and deep valleys, will make it a regiou well adapted to etock raising purposes.

The timber of the hills ia a variety of pine known as yellow or heavy pine. The grain of the wood ia straight, rather coarse, aplitting readily; and where the trees have escaped the action of fires and violent galee, good, straight logs, free from knots, and forty to eixty feet in length, and from twelve to twenty-four inches in diameter, can be obtained in abnndance. Spruce of good quality is found among the canons in the interior, and white birch, oak, and elm of medium size among the hills on the eastern slope.

The water throughout the hills is excellent in quality, mostly derived from springs among the limestone or the granitic or sohistose rock. Only in localities among the foothills is it contaminated by alkali.

There waa no evidence found that the Indians ever lived in the hills or ever visited them, except in the spring to cnt lodge poles, or occasionally stop and hunt deer among the foot-hilla while passing from the agencies to the Upper Missouri. The only reason advanced for the cause of their not living in the hills is the prevalence of severe thunder etorms and the frequency of trees being strnck by lightning.

The Rain-Fall.

The approach of the rainy seeson is always regarded with unusual interest in California, as on its character depends the general prosperity of the state for the ensuing year. The rain-fall here is not only very irregnlar from year to year, but it also varies greatly in different sections. The average rain-fall in San Francisco is about twenty inchee, while at Stockton it is but little more than half that amonnt, and a little farther down the San Joaquin valley it is considerably less than one-half. In this connection the following table, compiled for three seasons by the Engineer's department of the Central Pacific railroad company, will be read and studied with intereet:

California.

Stations.	Seasons. 1874-75.	'73-74.	'72-73.
San Francisco	18	23	18
Niles	12	14	14
Livermore	12	12	10

Terrace	7	2	2
Promontory	11	11	5
Corinne	13	12	14
Ogden	14	11	14

It will he observed that the points at which these observations are taken are along the main railroad lines, and in directions nearly central across the State north and south and east and west, and extending in an easterly direction over the Sierraa across the State of Nevada, and into the Territory of Utah.

The rain-fall is quoted at the summit of the Sierra, 7,000 feet ahovo the level of the aea, where it measenres an average of forty-four inches. Twenty miles beyond that point it decreases to about one-third that amount, or fifteen inches. Passing through the State of Nevada the fall varies from twenty inchee on the highest ridges to four inches in the lowest valleys.

In California, when the averagé at San Francisco reaches twenty-two inches, that amount has generally heen found sufficient to secure good crops throughout the State. When the amount here reaches thirty inches it is accompanied by destructive floods, and when it drops to or below fifteen inches a desiructive drouth is sure to follow. During the winter of 1863-64 only ten inches of rain fell in thie city, and we conecquently experienced the terribly destructive drouth of 1864. Thus far the present season indicates a flood year.

Although the average amount of rain-fall in any given section should be largely considered in selecting a location for farming in California, the productiveuess of a location is not always in proportion to the amount of rain which falls upon it; for some portions of the State will produce a hetter crop of any given product with eix inches of rain than can be secured from other sections with twelve or even twenty inches. The difference in yield is often aa largely due to the topography of the country, the general characteriatios of the soil and atmosphere, as to the amount of rain-fall.

Arrangements for the Centennial.

The Act of Congress which provided for "celebrating the one hundredth Anniversary of American Independence, by holding an International Exhibition of arts, manufactnrea, and products of the soil and mine," authorized the creation of the United States Centennial Commission, and entrusted to it the management of the exhibition. This body is compoaed of two commissioners from each State and Territory, nominated by the respective Governors, and commissioned by the President of the United States. The enterprise, therefore, is a distinctly national one, and not, as has sometimes been steted, the work of a private corporation.

The exhibition will be opened on May 10th, 1876, and remain open every day, except Sunday, until November 10th. There will be a fixed price of fifty cents for admission to all the buildings and grounds.

The Centennial grounds are situated on the western bank of the Schuylkill river, and within Fairmount park, the largest park in proximity to a great city in the world, and one of the most beautiful in the country. The park contains 3,160 acres, 450 of which have been enclosed for the exhibition. Besides this tract, there will be large yarde near by for the exhibition of stock, and a farm of forty-two acres has already been snitably planted for the tests of plows, mowers, reapers, and other agricultural machinery.

The exhibition buildings are approached by eight linee of street cars, which connect with all the other liuea of the city, aud by the Pennsylvania and Reading railroads, over the tracks of which trains will also run from the North Pennsylvania and Philsdelphia, Wilmington and Baltimore railroade. Thus the exhibition is in immediate connection with the entire railroad system of the country, and any one within ninety miles of Philadelphia can visit it at no greater cost than that of carriage hire at the Paris or Vienna exhibition.

The articles to be exhibited have been classified in aeven departments, which, for the most part, will be located in appropriate buildinga, whose several areas are as follows:

DEPARTMENT.	BUILDINGS.	ACRES COVERED.
1. Mining and Metallurgy, 2. Manufactures, 3. Education and Science,	Main Building.	21.47
4. Art,	Art Gallery,	1.5
5. Machinery,	Machinery Building,	14.
6. Agriculture,	Agricultural Building,	10.
7. Horticulture,	Horticultural Building,	1.5
Total,		48.47

This provides nearly ten more acres for exhibiting space than there were at Vienna, the largest international exhibition yet held. Yet the applicationa of exhibitora have been so numerous aa to exhaust the space, and many important classes of objects must be provided for in special buildings.

An important special exhibition will he made by the United Statee Government, and is being prepared under the supervison of a hoard of officers representing the eeveral executive departments of the Government. A fine building of 4½ acres is provided for the purpose, space in which will bo occupied by the war, treasury, navy, interior, postoffice and agricultural departments and the Smithsonian Institute.

The Women's Centennial Executive Committee have raised $30,000 for the erection of a pavilion in which to exhibit every kind of woman's work. To this collection women of all nations are expected to contribute.

The list of special buildings ie constantly increasing, and present indications are that their total number will be from 200 to 250. Most of the important foreign nations—England, Germany, Austria, France, Sweden, Egypt, Japan and others—are putting up one or more structures each for exhibiting purposes, or for the use of the commissioners, exhibitors and visitors. Offices and headquarters of this kind, usually of considerable architectural beauty, are provided by the States of Pennsylvania, Ohio, Indiana, Illinois, Michigan, New Jersey, New York, Connecticut, Massachusetts, New Hampshire, Missouri, Kansas, Virginia, West Virginia, Nevada, Wisconsin, Iowa and Delaware, and it is likely that others will follow tho example.

A number of trade and industrial associations, which require large amounts of space, will be provided for in epecial buildinge. Among these are the photographers, the carriage builders, the glass makers, the cracker bakers, the boot and shoe manufacturers, besides quite a number of individual exhibitore. The great demands for space will probably render this necessary to a considerable extent, especially for exhibitors who have been tardy in making their applications. In the main exhibition building, for example, 333,300 square feet of space had been applied for by the beginning of October by American exhibitora only; whereas the aggregate space which it has been possible to reserve for the United States Department is only 160,000 square feet, about one-third of which will be consumed by paseage ways.

The machinery building, like the others, is already fully covered by applioations. There are about 1,000 American exhibitore in this department, 150 Englieh and 150 from other European countries—which is about 250 more than entered the Vienna machinery exhibition. Extra provision is being made for aunexes to accommodate the hydraulic machinery, the steam hammers, forges, hoisting engines, boilers, plumbers, carpentors, etc.

Power in the machinery hall will be chiefly supplied by a pair of monster Corlise engines. Each cylinder is 40 inches in diameter, with a stroke of ten feet; the fly wheel ie 31 feet in diameter and weighs 55 tons; the horse power is 1,400 and the number of boilers is 20. This engine drives about a mile of shafting.

For the art exhibition, the most eminent American artiets are understood to he at work, and it may be confidently stated that, especially in the department of landscape painting, the United States will present a finer diaplay than the public has heen led to expect. Quite aside from the contribntiona of American artists, applications from abroad call for more than four timee the exhibiting space afforded by the great Memorial hall. Provision for the surplua will be made in temporary fire-proof buildings, thongh all exhibiting nations will be represented in the central art gallery.

The Secretary of the Navy has arranged that a United Statea war vessel shall call next spring at convenient European ports, to collect and transport hither to the exhibition the works of American artists resident in Europe. Among the ports thus far designated, are Southampton for England, Havre for France, Bremen for Germany, and Leghorn for Italy, to which, if desirable, othera may be added.

Mr. Bell, the eminent English sculptor, who designed the groups for the plinth for the great Albert memorial in Hyde Park, London, is reproducing in terra cotta, at the celebratsd worke in Lambeth, the one which symbolizes Americoa. The figures in this group are colossal, covering a ground space of 15 feet square. It will probably be placed in the great central gallery, opposite the principal entrance.

The art exhibition will include, in addition to the works of contemporary artists, representative productions of the past century of American art—those, for instance, of Stuart, Copley, Trumbull, West, Alston, Sully, Neagle, Elliot, Kensett, Cole. These, as well aa the works offered by living artists, will be passed upon by the committee of selection, who will visit for the pnrpose, New York, Boston, Chicago, and other leading cities, in nrder to prevent the needless transportation to Philadelphia of works of art not up to the standard of admission.

A large number of orders and fraternities have signified their intention to hold gatherings at Philadelphia during the period of the exhibition. Among those which may now be enumerated, are the Grand Lodge of Pennsylvania, Indepeudent Order of Odd Fellows; the Grand Encampment, Independent Order of Odd Fellows; Grand Lodge, United States, Independent Order of Odd Fellows; Grand Commandery Knights Templar; Grand Army of the Republic; Presbyterian Synod; Caledouian Club; Portland Mechanic Blues; Welsh National Eistedfodd; Patriotio Order Sons of America; California Zonaves of San Francisco; an International Regatta; the Life Insurance Companies; National Board of Underwriters; State Agricultural Society; 2d Infantry, N. G. of California; Philadelphia Conference, Methodist Episcopal Church; Cincinnati Society California Pioneer Socicty; American Dental Convention; Catholic Total Abstinence Union of America; Independent Order of B'nai Brith; National Alumni Association; Salesmen'e Association; 5th Maryland Regiment; American Pomological Society; Malster's Association of the United State; Army of the Cumberland; Humboldt Monument Association; Christopher Columbus Monumeut Association; Board of Trade Convention; International Typographical Congress; Rifle Association of the United States; Centennial Legion; Philadelphia County Medical Society; International Medical Congress; Old Volunteer Fire Department of Philadelphia.

MINING THE GREAT CIVILIZER.—The London *Mining World* discourses on tho effects of mining on civilization at conaiderable length, and very logitimately concludes as follows: It is not too much to eay that all the civilization of which we hoast may be traced to the application of the metals and to the use of coal. Wherever nations have learned to mine and work metals, they have become powerful and rich, subduing their neighbors either by force of arms or by greater industrial activity, and in either case acquiring their wealth. In the earlier stages, those who possessed the metals made an easy prey of their rivals, and in the present day nations mining their coals and metals do in a better and more elevated sense outstrip their competitors and become the masters of the world. All history teaches that those nations which learned to mine and work metals became wealthy, powerful and civilized, whilst those which have had no mining industries or no metallic manufactures have remained in a state of barbarism, and that such at the present day is the distiugnishing feature of eavages. Mining industry is, indeed, the foundation of all civilization and the chief basis on which all industries must rest, as well as being at the aame time the principal element of progress. Without it the working clasa could gain little beyond the mere necessities, and, as we have often shown that coal and iron are the first requisites of national prosperity, so it is to mining that we must refer the advancement of the present age.

THE cost of maintaining the inaane at the Stockton asylum is forty-three cents per capita per diem, which is less than the cost of maintaining any other similar institution in the United States.

Useful Information.

Notes on Iron.

A flanged tire bar, 5 in. x 1.8 in. and contains 10.2 square inches, requires upward of 200 tons pressure on a pair of ordinary shears to cut it open. In one experiment 210.6 tons were required.

A new railway bar has been known to break in three pieces on simply falling from a wagon.

A cast iron pillar, loaded with 97-100ths of its calculated ultimate breaking strain, bore the load six months and then broke.

Locomotive tires are gradually extended in circumference by the friction to which they are subjected. They often become so loose upon the wheels as to require to be taken off and set new.

Steel swells in hardening. Iron absorbs carbon and swells in case-hardening, as well as in conversion into steel. Forgings of scrap iron are liable in case-hardening to absorb carbon unequally, and to twist or vary, owing to the irregularities of the iron.

In punching long angle iron with closely pitched holes, as for riveting, the iron is stretched, often half an inch in ten feet, and a different template should be used in laying off the holes in such iron, so as to allow for the stretching.

Cast steel, when hardened to too great an extent, has been known to explode violently. A case was reported in the *Franklin Institute Journal*, for 1844, where a hardened steel step or bushing 1¾ inches in diameter, having a one-eighth inch hole, exploded with a report like a pistol.

A steel wire or bar of steel of whatever diameter, having a tensile strength equal to 150,000 pounds per square inch, would just support its own weight, if 8 3-5 miles (46,166 feet,) long and suspended freely from one end.

Forgings which have been hammered when early cold often prove very brittle, a quality occasionally attributed to crystallization. Such forgings, however, if brought to a good heat and allowed to cool slowly, recover their toughness.

Hard cast iron, when cast in very large masses, and allowed to cool slowly, is found to become soft. Heavy guns, when cast solid from hard iron, are found to bore easily.

The strength of 1¼ inch bolts made of a given quality of iron, being twenty-three tons per square inch, Mr. Brunell found the strength of one-inch bolts of the same iron to be twenty-five tons to the square inch, while three-fourth inch and five-eighth inch bolts of the same iron bore respectively twenty-seven and thirty-two tons per square inch.

By successively reheating and reworking Swedish iron, Mr. Wm. Clay found that while the original tensile strength was 43,904 pounds per square inch, its strength at the sixth reheating was 61,824 pounds. Subsequent working reduced the strength until at the twelfth heating it again stood at 43,904 pounds.—*Exchange.*

To Make Leather Water-Proof.—The *Bayerisches Industrie und Gewerbeblatt* contains the proceeding, which has been patented in Bavaria, for rendering hose of fire engines completely water-tight, so as to withstand the greatest pressure. The hose are, after they have been cleaned and dried, impregnated with a mixture of 100 parts of glycerine of 24° R. and 3 parts of carbolic acid, which may be done either by drawing the hose through the liquid, or better still, by brushing it well in. Thus treated, the hose are said to preserve a certain degree of dampness, without, however, being liable to rotting in the least degree, and so suffering deterioration in quality and durability. The brass fittings of the hose are attacked only imperceptibly by the acid contained in the composition; but even this may be easily prevented by giving them before impregnation a coating of weak shellac varnish, or by greasing them well with tallow. The hose must be cleaned every time they have been used, dried, and impregnated anew with the liquid. As it does not affect the mixture, hose prepared in the above manner do not freeze easily at low temperatures. If the preparation named is effective as stated when used in connection with hose, it should be especially valuable for an application for leather boots for miners'

To Fix Paper on Drawing Boards.—Take a sheet of drawing paper and damp it on the back evenly with a wet sponge and clean water. While the paper is expanding, take a spoonful of wheat flour, mix with a little cold water, and paste it a modarately thick paste; spread the paste round the edge of the drawing paper one inch wide with a feather, then turn the drawing paper over and press the edges down on the board. After this take four straight pieces of soft wood, three-fourths of an inch by two and three-fourth inches wide; place them on the edge of the drawing paper, and put a large book or heavy weight on each corner to make the paper adhere firmly to the board. In about an hour's time the paper will be straight and even, and will be ready for executing a drawing. When the drawing is finished, take a sharp knife and cut at one corner of the paper, then take a scale, and cut it around the edges, and the paper will come off easily. Turn over and take the dry paste off with a knife, and all will be perfectly clean, and no paper will be wasted.

New Speaking and Hearing Trumpet for Divers.—An apparatus patented by Bremen & Co., of Kisl, and introduced for trial into the German Imperial Navy, not only enables the diver to communicate with those at the air-pump, but also to hear distinctly, to a depth of sixteen fathoms, every word spoken at the surface. The absolute safety of the diver being thus secured, it is expected that they will be able to work for smaller wages, thus rendering their services available in many cases in which they otherwise would be too costly. It is said that the invention is very simple, and can be attached, without much expense, to any diving apparatus. The main principle involved is the application of vibrating metallic plates for the propagation of the sound, without, however, allowing them to come in contact with the water.

New Use for Molasses.—In consequence of the low price of molasses, attempts are being made in France to introduce it in the place of manure. It is used either in a liquid form, diluted with seven parts of water, or as a powder; and just at this moment it is cheaper than ordinary manure, while it contains all its essential elements in equal abundance. As soon, however, as the cold weather comes on, the molasses will again be required for cattle-feeding purposes, and will probably rise to a price at which it would be useless for manure.—*Jour. of App. Science.*

The molasses above referred to is that obtained in the process of the manufacture of sugar from beets. Such molasses at the Sacramento sugar factory is used for distilling purposes, and converted into brandy.

New Use for Sawdust.—Sawdust can be converted into a liquid wood, and afterwards into a solid, flexible and almost indestructible mass, which, when incorporated with animal matter, rolled and dried, can be used for the most delicate impressions, as well as for the formation of solid and durable articles, in the following manner: Immerse the dust of any kind of wood in diluted sulphuric acid, sufficiently strong to affect the fibers, for some days; the finer parts are then passed through a sieve, well stirred and allowed to settle. Drain the liquid from the sediment, and mix the latter with a proportionate quantity of animal offal, similar to that used for glue. Roll the mass, pack it in molds, and allow it to dry.

Match Marks upon hard-finished walls may be removed by rubbing the walls with a bit of pumice stone. Prevention is better than cure, and if mats made of sandpaper, cut in circular or hexagonal shapes, fastened upon pasteboard, and bound with bright colored braids, with a ring attached to a sack, are hung near the match-box, these unsightly disfigurements may be entirely prevented.

Good Health.

The Philosophy of the Lungs.

The office of the lungs, in its relation to health and life, is so important in the human organism, that everybody ought to understand it.

The work performed by the lungs is of two kinds. First, they endow with life the elements which repair the wear and tear of the body. The stomach digests the food we eat, but has no power to make that food into blood. The product of digestion is a white fluid, devoid of life, and possessing in itself no power of assimilation. It is sent to the lungs to be vitalized—or, in other words, endowed with life, and made capable of entering into combination with the tissues of the body. This white fluid is called chyle, and when the lungs have acted upon it, becomes bright red blood, in which condition it is sent to the heart to be distributed throughout the system. Every breath we draw manufactures a certain quantity of new blood. It is in this way that the food we eat imparts strength and health to our bodies.

No sooner is one meal digested by the stomach, and made into blood by the lungs, than the sense of hunger returns to tell us we must eat again. If we do not heed this demand for more food the making of new blood stops and the body grows weak. This renovation of the blood is going on unceasingly. The quantity of new blood made depends on the size of the lungs. A man with small lungs only breathes a small quantity of air, and can only make a proportionate quantity of blood. With large lungs more air is inspired, and consequently more blood is made. This is why those having large lungs are strong, muscular men, while others with small lungs are thin and weak. It is a law of nature, and you cannot find in all the world an instance of a stout, muscular man with small lungs. The nutrition of the body is governed by the size of the lungs and the freedom of the breathing.

This being the case you can understand how essential it is to health and strength that the lungs should always be kept free from obstruction. If you permit colds to settle on the chest, and the mucous lining of the air tubes to become congested and inflamed, you by that prevent the lungs from doing their appointed work, and inevitably lose in flesh and strength thereby.

This explains the reason why all lung diseases are characterized by loss of flesh. That malady called consumption is so named from this very peculiarity. The body consumes or wastes away, because the lungs are obstructed by tubercles. So, also, of catarrh and bronchitis, though in a less degree. They impair the blood-making power of the lungs by clogging the air tubes with phlegm and mucous, and in this way injure the general health, and weaken the body. To remedy this weakness and increase the flesh, it is common to advise, in these lung cases, all kinds of nourishing food, under the delusion that the fault is in the stomach. But they do not good, for the reason that assimilation does not take place in the stomach. The stomach may be supplied with the strongest nourishment, and may perfectly digest it, and yet the patient will continue to lose in proportion to the extent the lungs are diseased. But improve his breathing, and from that moment, without any change in his diet, he will begin to gain.

Good health depends on the rapid transformation of matter—on the constant introduction of new elements of nutrition into the blood, and the constant expulsion of old, worn out elements from the blood. This brings us to the second duty performed by the lungs. They not only give us our strength by making new blood from the food we eat, but they purify the old blood by casting out its most corrupting impurities. Every breath we draw comes back from the lungs loaded with carbonic acid. Carbonic acid is formed by the combustion of the fatty tissues of the body. In this way animal heat is generated and the warmth of the body maintained. Its formation is essential to life. It takes place every moment of our being and must be expelled by the lungs as fast as it is formed or our health suffers.

Now put these facts together and you cannot fail to understand why all lung diseases are so dangerous to health. Catarrh, bronchitis, and consumption all have their seat in the air passages through which we breathe. They obstruct the lungs, and by that impair nutrition and corrupt the blood. If the blood is not sufficiently renewed by the introduction of fresh elements it loses its power of imparting nutrition. If it is not only poor in quality, but impure through the failure of the lungs to effectually remove the carbonic acid, its circulation spreads weakness and derangement through all the organs of the body. It does not impart to them the strength necessary to the performance of their own functions. The brain and nervous system show their distress by chills and fever, headache and pain—the heart by a fitful pulse and feeble circulation, the liver by torpor and biliousness, the stomach by capricious appetite and loss of tone, and so on. It is thus that we have in all lung cases a wide range of symptoms, many of which you would suppose to be entirely independent of the lungs, when in reality they all spring directly from their condition.

Now, on the subject of treatment. Suppose your general health to be impaired in the way explained, you could not expect any permanent benefit to result from treating the loss of flesh, bad circulation, torpid liver, disordered nerves, etc., while their cause remains in operation. Their cause is the state of the lungs, and these are but the effects or symptoms. No cure ever yet resulted from such a course. No remedy devised by man can cure the symptoms while their cause remains in force. Restore the function of the lungs and all these general effects will disappear of their own accord. The most that is ever accomplished by treating symptoms is a little temporary relief, while, by going to the root of the evil, and trusting the lungs, the disease itself and the symptoms disappear together, and the cure is radical.

In explaining these matters I have endeavored to give the reader an insight into some of the higher mysteries of medical science, which as yet are but imperfectly understood, even by the general profession. The philosophy of respiration teaches the paramount importance of the lungs over all organs of the body, the injury which results to health from even the slightest obstruction of their function, and indicates clearly the remedial means which alone can guide to success in the treatment of lung complaints.—*Robert Hunter, M. D.*

Poisoning by Arsenical Wall Paper—Not Green.—Cases of arsenical poisoning occasioned by living in rooms the walls of which were covered with paper colored green by arsenite of copper have frequently been recorded. Lately a case of arsenical poisoning has come under my notice, caused by inhaling the dust from paper not colored green. The family of a gentleman, Mr. Jones, residing in New Ross, suffered so severely from symptoms usually produced by arsenic that he was induced to get the wall paper of his house examined. Out of seven kinds of paper, six were found to contain arsenic. No. 1, an olive-green paper, with deep green flowers and gold-like lines, contained an immense amount of arsenic in the two green colors and the "gold." No. 2, a faint lavender-watered paper, contained arsenic in large amount. No. 3, a white paper with green flower, contained a very large amount of arsenic. No. 4, a paper with red and green flowers on a gray ground, was highly arsenical. No. 5, a dark olive-colored paper, with gilding, did not contain much arsenic. No. 6, a pale green and white paper, also contained only a small amount of arsenic—much less than was put on the lavender paper. Mr. Jones' family had not suffered from symptoms of arsenical poisoning until shortly after the house was papered with the above; and the symptoms disappeared shortly after they left the house preparatory to the removal of the paper.—*The Medical Press.*

Domestic Economy.

Choice Treatment of Foods.

In the choice of foods we cannot exercise too much care. It is cheaper to procure only the very best articles. All vegetables and fruits should be grown on the best soils, and the fertilizers used should be well decomposed and not fresh and rank. Partially decayed food of whatever kind should be avoided. For breads, the best white wheat is none too good. If grown in new soil it is likely to be better and to contain abundance of the mineral matter so needful to health. Fruits for eating without cooking should be ripe, tender and not too tart; while those for cooking may be either sweet or sour, but they must possess the peculiar quality of retaining when cooked their best flavors. Potatoes should be fresh and ripe—old ones are less wholesome, especially when they have been exposed to the light and air, and bruised by much handling, or long exposed to the cold.

Animal food should be chosen with great caution. Only healthy animals should be used for eating. They should neither be too old nor too young, too fat nor too lean. In butchering, all the blood should be removed from the body, as otherwise the flesh putrefies readily. It should be thoroughly cooled before eating. It is also desirable that the animal be not killed for several hours after eating or after fatigue. The long journeys animals are sent on crowded, filthy cars, render their flesh unwholesome.

The treatment of animal food is a matter of importance. Why do we cook it at all? First, to render it more pleasing to the sight; second, to develop its best flavors; and third, to render it digestible and palatable. Flesh cooked too much is rendered innutritious and indigestible; if cooked too little, it is disagreeable eating. Liebig said he would never have flesh subjected to a higher temperature than 170° F., except for a few minutes after it is put into the pot, when it may be submitted to a temperature of boiling water in order to coagulate the albumen into a sort of crust on the outside to hold in the flavors that might otherwise be evaporated. In roasting meat, also, let the heat at first be high, and gradually decrease to the boiling point for the same reason. Stewed meats are more wholesome and nutritious than any other. The process renders flesh tender and succulent and easy of digestion.

Fish Flour.—A novel and remarkable article of food, prepared from the products of the ocean, has lately been brought prominently forward—this is fish flour. It is not as yet manufactured in any great quantity, as the article is still new in the market, and consequently there is no great demand for it. The flour is prepared in Norway, from dried cod-fish of the first quality; it is thoroughly desiccated and then ground in a mill. There are two qualities, the coarse and the fine-ground. It is especially the former which has found favor with the public; from it an excellent dish of preserved fish can in a short time be prepared; while the finest ground is used for fish puddings, a dish highly appreciated in Norway and Sweden. In Catholic countries, in localities where there is no regular supply of fresh fish, it is presumed this article will be more particularly important.

Barley and Bread Soup.—Take three ounces of barley, one and a half ounces of stale bread crumbs, one and a half ounces of butter, one-half ounce of salt, and one quarter ounce of parsley. Wash and steep the barley for twelve hours in one-half pint of water, to which a piece of carbonate of soda, the size of a pea, has been added; then pour off the water not absorbed, and add the crumbs of stale bread, three quarts of boiling water, and the salt. Digest these in a salt-glazed covered jar, in the oven, or boil them slowly in a well tinned covered pan, for from four to six hours, adding the chopped parsley, with the butter, thirty minutes before the expiration of the time of boiling.

Horseradish Sauce.—Grate as much horseradish as will fill a breakfast cup, mix with it two teaspoonfuls of powdered white sugar and one each of salt and pepper, a dessertspoonful of made mustard, and enough vinegar to make the whole as thick as thick cream. A small cupful of cream is also a great improvement. To use with roast beef the sauce is heated by being placed in a jar in the oven till warm, but it must not boil; and it is very good cold, to eat with various cold meats. Double the quantity may be made at a time, and it will keep for some weeks if bottled.

Buckwheat Cakes.—One quart of buckwheat flour and a half a pint of Graham meal. Mix with lukewarm water into a batter, stir in a teacupful of good yeast sponge or a half cent's worth of bakers' yeast; mix in an earthen or stone vessel, and set over night in a warm place to rise. If the temperature and yeast have been just right, the batter will be light and sweet, and not need soda. It should be considered a mistake when the ferment needs neutralizing, and care taken to set cooler or correct the yeast.

Cheese Sandwiches.—Take two-thirds of good cheese, grated, and one-third of butter; add a little cream; pound all together in a mortar; then spread it on slices of brown bread or gems; lay another slice over each; press them gently together, and cut in small square pieces.

MINING AND SCIENTIFIC PRESS

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

ADVERTISING RATES.—1 week.	1 month.	3 months.	1 year.
Per line..... .25	.80	$2.00	$5.00
One-half inch.....$1.00	3.00	7.50	24.00
One inch..... 1.50	4.00	12.00	40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscribers.

We wish to thank those subscribers who send in their renewals to the PRESS promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Japanese Iron Industry; An Improved Ore Feeder; Rights of Stockholders; Death of the Hon. Benjamin P. Avery, 353.
Ball's Sweeping Dredge; Notices of Recent Patents, 360. Raised Water by Compressed Air; Antimony; Bridge Building, 361. The Emma Mine Again; Rain Table; General News Items, 364.
ILLUSTRATIONS.—Cochran's Automatic Ore Feeder, 353. Raising Water by Compressed Air, 361.
CORRESPONDENCE.—Bald Mountain Mining District, 354.
SCIENTIFIC PROGRESS.—Proof that Electricity is not a Fluid; Fruit in Prehistoric Times; To Fix Magnetic Curves; Nature of the Tails of Comets; Copper Pipe Electrified by Steam; Molecules—Their Relation to Pressure; Action of Plants on Impure Water; The Limit to the Carburation of Iron; Hot Glass a Conductor to Electricity, 355.
MECHANICAL PROGRESS.—Vulcanized Fiber—A New Water-Tight Joint; Superheated Steam in Common Engines; Steel Wire Rope; The Demagnetization of Watches; Car Building for the World; A Substitute for Hydraulic Lime; The English Eighty-one-ton Gun to be Eclipsed; American Small Arms, 355.
MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 356.
MINING SUMMARY from various counties in California, Nevada, Arizona, Montana, Oregon, Idaho and Utah, 356-7.
USEFUL INFORMATION.—Notes on Iron; To Make Leather Water-Proof; To Fix Paper on Drawing Boards; New Speaking and Hearing Trumpet for Divers; New Use for Molasses; New Use for Sawdust, 359.
GOOD HEALTH.—The Philosophy of the Lungs; Poisoning by Arsenical Wall Paper—Not Green, 359.
DOMESTIC ECONOMY.—Choice Treatment of Foods; Fish Flour; Barley and Bread Soup; Horse-radish Sauce; Buckwheat Cakes; Cheese Sandwiches, 359.
MISCELLANEOUS.—The Twenty Cent Coinage; Report of the Director of the Mint; Potatoes for Europe; An Important Revelation; The Future of Mariposa; Engineers of the Sutro Tunnel; Shut Down, 354. Geology of the Black Hills; The Rain Fall; Arrangements for the Centennial; Mining the Great Civilizer, 358. Lower California Mines; Dangers of Hydrogen Toy Balloons; American Plate Glass, 362.

RENEW YOUR SUBSCRIPTIONS.—With encouraging rains, good mining prospects, a rapidly increasing population, public improvements and new manufacturing and industrial enterprises springing up throughout the coast, we believe the ensuing year will be one of such progress and importance that no subscriber of the PRESS can afford to miss the record of events and discoveries which will be reported in the successive issues of this journal.

THE Centennial Commissioners for Nevada have agreed to the following: "*Resolved*, That we respectfully request the people of California and Oregon to join us in the erection and maintainance of a building sufficient to accommodate the people from the Pacific Coast, to be known as the Pacific Coast headquarters."

FIRE was put under the boilers at the pan department of the California mill on the 22d ult. for the first time. The mill will be started up in a few days on tailings saved from the Consolidated Virginia mill during a number of months past.

THE Storey county papers now estimate the total loss by the Virginia fire at $10,000,000. Insured for $2,500,000. This is largely in excess of the first estimate.

Ball's Sweeping Dredge.

Those who have recently been in the vicinity of the old ferry slips, between Broadway and Vallejo street wharves, have probably noticed a peculiar large dredging machine, which gave no apparent indication of its nature until the hinge scows, filled with mud, were towed away from it by an attendant sprite in the shape of a steam tug. No long pole extends into the air as in the clam-shell dredge, and no moveable buckets are seen bringing their load from the bottom of the bay; therefore, although the general impression of the machine is that it is a mud digger, there were no apparent indications of its being at work, except that spoken of. Nevertheless, it is hard at work, but, contrary to the usual preconceived notions of such machines, performs its labor quietly and thoroughly without making any great noise or splashing mud in every direction.

This dredge is of a new design, by John A. Ball, and is at present engaged on a contract for the city. The new features of the machine are several, and the whole is a very ingenious contrivance, complete in all its parts. This is, in some respects, an experimental dredge, being the first one built by Mr. Ball with all his improvements combined. It is called "Ball's sweeping dredge."

The "sweeping" arrangement, which is a prominent feature, is very simple, but effective, and so far has worked in a manner to exceed the expectations of the inventor. The dredge (which is described hereafter) is so attached to an auxiliary scow as to admit of its being swung back and forth across a channel or slip on the radius of a circle, without the necessity of having any anchors down or lines stretched from dock to dock to manipulate it.

A dredge tender, or scow, twenty by sixty feet, is held in position by four "spuds" or beams, which are dropped down, one from each corner, into the mud. This fixes it firmly in place. A "tongue," like the large tongue of an ox wagon, joins the tender and dredge together, the end on the tender being fixed on a pivot. From each end of the tender projects a heavy beam to the outer end of which a chain is attached. This chain passes from the end of one of the beams across the front of the dredge and then back to the beam on the opposite end of the tender. A bight in the chain passes around a reversible pulley connected with the machinery on the dredge.

Now, when the dredge has started work on one side of the slip or channel, a strain is constantly kept up on one side of the chain. This has the effect of slowly and gradually bringing the dredge across to the other side of the channel, without interrupting the digging, or hoisting any spuds to move. The tender all the time remains stationary, being held by its spuds; but the dredge is swung across a channel 200 feet wide, digging mud all the time, without stopping the machinery. The speed of the lateral motion of the dredge can, of course, be regulated to suit the character of the ground being worked.

The tongue which joins the tender and dredge together can be shortened or lengthened at pleasure. Accordingly, when the dredge has worked across the channel, the pivot on the tongue is raised and moved back two feet, which brings the dredge two feet nearer the tender. Then the strain is brought on the other end of the chain, and the dredge is "swept" back across the channel, digging in new ground two feet nearer its tender. This operation is repeated until the dredge and scow are brought together, when a large spud is dropped from the dredge to keep it in place while the tender is being moved back. Two lines from the dredger revolve two shafts on the tender, by which means the four corner spuds are raised and the tender moved out to the end of the tongue, when the spuds on the tender are dropped again, that on the dredger raised, and the dredger commences its work once more.

It will be seen from this that the machine will dig across a channel, 200 feet wide and two feet deep, eight or ten times without having to handle any anchors, spuds or lines, saving a great deal of time usually consumed in changing position. If necessary, the space can be dug to the required depth, say from two to thirty feet, without having to change; but it is usually desirable to dig over the surface two or four feet each time, and go over it again until the necessary depth is attained.

The improvements in the digging apparatus itself are many, various changes in details over those before built having been made. The principle is that of having large buckets or scoops attached to an endless chain, pass down an inclined "ladder," and up again, each bucket dumping its load as it comes to the top. Although the principle itself is not new, such a radical variation has been made from similar dredges in existence that all the details are changed. In the first place the buckets, instead of passing down under the ladder and up over the top, pass down the top and up on the under side, thus gaining advantages hereafter explained. Then again, the buckets are very large and have a patent self-dumping bottom which is substantial and strong, and which works very effectively.

The endless chain, which passes down over two large six-foot pulleys at the bottom of the ladder, is made of heavy wrought iron. Friction rollers are placed every few feet in this chain, and it is so arranged as to run both down and up on a track, which carries both the weight of the buckets and chain. By this means the friction is reduced to a minimum. There are ten buckets placed at equal distances apart, and each holding one and three-quarter cubic yards of mud or earth. These buckets are fifty inches wide on the cut.

The main shaft at the upper end of the ladder carries two three-foot pulleys four feet apart, and around each of these pulleys, the heavy endless chain passes, going around similar pulleys at the bottom of the ladder. The buckets are secured to these chains at equal distances apart, being connected with the chains at a point below their middle line. A link connects their upper ends with a cross bar which connects the chain. As these buckets come to the pulleys at the upper end of the ladder an automatic arrangement releases a hinged gate or bottom, while the buckets are passing around the wheel, so that the contents are dropped into the scows underneath. As the bucket passes still further over the wheel the hinged bottom falls back shut of its own weight and remains closed until it again comes to the top. The buckets are armed with heavy wrought iron teeth on the cutting edge, so as to stand any strains to which they may be subjected. There are no springs or ratchets connected with this opening device, it being quite simple in operation, but difficult to describe without engravings.

The power is derived from two 15x15 vertical engines and two large boilers, 16x4. The engines are geared up to gain power. The scow itself is 94x31 feet. It is very heavily and strongly built, being composed really of three scows joined together by heavy timbers so as to make one solid structure. The ladder is inclined down between the two smaller fore and aft sections, and the buckets accordingly pass between them. The after end is supported by another large scow, so as to leave a space of thirty feet laterally between it and the other two sections. This space is necessary to float the mud scow in under the dredge, so that the buckets can dump their contents into them. A scow is floated in under the buckets and gradually passed through to the other side, being loaded on its way. This avoids confusion with the tug, as it leaves an empty scow on one side and takes the full one from the other without unnecessary backing and filling. All the splashing and mud throwing is done, therefore, on the inside of the machine, where it falls back into the scow.

The raising and lowering of the ladder is effected by a very simple means, and is all accomplished by machinery, without stopping the digging operations at all. In the upper part of the dredger, over the machinery and entirely out of the way is a small car rigged like a saw-mill carriage upside down. By applying the power and drawing this car back it draws a chain which passes over a pulley down to the lower end of the "ladder," and thus hoists the ladder, and regulates the depth of the digging.

The dredge is now working on a contract for the city at 12½ cents a cubic yard, which is a margin over actual expenses, but it is not a sufficient price. Mr. Ball has taken out 25,000 cubic yards of mud. It is admitted by all who have seen the machine run that no one tug can take away the mud as fast as it is filled into the scows. Some little difficulty has been experienced from the fact that the machinery sunk the scow lower than was expected, leaving a small margin for the scows, when light, to pass under to be loaded. This will be remedied by raising the scows from below, without changing or moving any of the machinery or upper works. The whole dredge, including extra expenses for experimenting, etc., cost upwards of $35,000.

They were dredging this week twenty feet below low tide, or an average depth of about twenty-four feet. It was not until this machine was at work on the Oakland bar, that the former prices for dredging came down to any fair figure. Those who had the city dredging for several years at fifty cents a cubic yard and afterwards for thirty-six cents, sold their machine to the city. It is claimed that the Ball is the most economical dredge yet invented, and that it will do double the work in the same space of time that any other dredge can do. The scows, of 105 cubic yards, are filled in from nine to fifteen minutes, the average time being less than twelve, or about nine cubic yards per minute. Mr. Ball is confident that in digging solid clay or hard pan, such as usually has to be blasted for other machines, he can dig at nearly the same speed that he digs the mud.

Mr. Ball has a number of patents on the machinery, in the United States and principal foreign countries. He has had quite a struggle for several years to introduce his machine to public favor, considerable opposition being manifested by interested parties; but now having a capitalist associated with him as a partner he is able to make contracts for work or make such improvements as suggest themselves. As very little can be understood about the machine by looking at it from the wharf those interested in such thing will be courteously received on board should they wish to examine the machinery.

THE Trinity *Journal* says: "Miners throughout the county are now washing with a full supply of water. Most of them will do more work before christmas this year than was done the whole of last season."

A MINERS' Union will shortly be established at Pioche.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

STEAM ENGINE BOILER.—Joseph Enwright, San Jose, Santa Clara county, Cal. This invention relates to certain improvements in the furnaces of steam boilers in which a large central flue is employed, having a grate in its front end, and a combustion chamber behind, with small return flues. The invention is especially intended to fit the furnace for using straw as a fuel, and it contemplates the use of what the inventor calls a ring grate behind the ordinary grate, so that he is enabled to do away with the extension mouth piece which is now attached to the furnace doors for that purpose. The invention further consists in an adjusting plate by which the size of the door opening may vary to fit the furnace for burning straw or wood; and lastly in the use of a cylindrical extinguisher or shield, containing a water hearth or floor, so that the loose straw is prevented from being blown about by the wind and any cinders or burning straw which may drop will be extinguished by the water. These improvements enables the inventor to make a portable or field boiler perfectly safe, and also makes it equally serviceable in burning straw or wood.

PLOWING MACHINE.—Theodore C. Stark, No. 631 Mission street, San Francisco. This invention is an improved machine for plowing and cultivating the soil, which can be either propelled by steam or drawn over the ground by horses. In this machine the inventor uses a series of ordinary plows ranged across the rear end of the wagon or plow frame, the main feature of the invention consisting in the employment of two or more parallel independent sliding plow-beams, to each one of which one or more plows is attached. These sliding plow-beams are so connected with pulleys, cranks or equivalent mechanism, that as the wagon or plow-frame progresses they are separately and alternately drawn upon, so that the plows which are attached to each beam, after they are pulled forward by the semi-rotation of its crank or pulley, will remain stationary during the back movement of the crank or pulley, while the other plows are being drawn forward in the same manner, thus drawing the entire series of plows through the ground while only one beam with its plows are working at one time. One, two or three plows can be attached to each beam, or even more if desired, but the inventor does not propose to use more than three to each beam or compound beam. At the forward end of each beam is an adjustable foot, by means of which the depth to which the plows are to be run is regulated. A curved handle is also provided which passes up through the platform directly above the plows, so that a person standing on the platform can adjust the point of the plows in the ordinary manner of holding a hand plow. Each beam is connected with one arm of a crank lever which is pivoted upon the platform, so that each beam and its gang of plows can be raised entirely out of the ground if desired. The inventor claims to provide a plowing machine which will draw a large number of plows with the same power that is required to draw a single gang.

BATTER FEEDER FOR CAKE MAKING.—Dennis H. Lafferty, San Francisco, Cal. This is an implement of domestic use, and is employed to feed the batter of which cakes are made upon the iron where they are to be cooked, with rapidity, and so as to obviate all waste and dripping. A suitable vessel with a handle, having its bottom conical in shape, is employed to hold the batter. At the bottom of the conical portion is a hole for the contents to pass. A stopper on the inside always lies over the opening by its own gravity. A rod projects from the lower end of this stopper, so it will be seen that where the vessel is lowered sufficiently to allow the stem to touch the iron, the valve or stopper is raised and thus a portion of the contents will escape. By raising the vessel the valve will be instantly closed and further flow cut off. With this invention no difficulty is experienced from drippings, as the flow is cut off so short by raising the vessel.

TRACTION WHEEL FOR HARVESTERS.—Wm. O. M. Berry, San Francisco, Cal. This machine relates to certain improvements on traction wheels, and more especially such as are employed on headers and mowing machines. It consists first in the employment of bars or ribs placed angularly across the face of the wheel, the angles being so great that before the end of the rib at one side has left the ground, the end of the next rib at the other side of the wheel face will be resting upon the ground, thus making the thread continuous and preventing the machine from sliding upon side hills. The second part of the invention consists in the construction of a peculiar double cup, shaped nut, having channels made in its outer face around the shaft or axle, and the spokes of the wheel pass the edge of this hub into these openings, where they are held by nuts so that the can be set up at any time.

ANOTHER vein of superior coal has been struck at the Utter mine, Coos bay, above the vein heretofore worked and of good quality good for blacksmithing purposes.

Raising Water by Compressed Air.

Want of water is one of the commonest inconveniences of life to all who live outside of cities, and most owners of country places spend a good deal of time in considering how to get such a supply as they want. Leaving hand labor and gravitation out of the account, there are three sources of power available—steam, water and wind. For raising water for private use steam would not often be economical, as in addition to the first cost of engine there must be a continued outlay for fuel and attendance. A water wheel is seldom available, especially in this country, as it requires a considerable stream which has at least a moderate fall. A hydraulic ram also needs a fall and a good deal of water. If either of these conditions is lacking its use is out of the question.

Wind power remains to be considered. It costs nothing; the wheel will run in the night as well as the daytime and with no attention. Wind wheels have become numerous in California, and in many places where irrigation is required or large quantities of stock are kept, are an absolute necessity. But granting the efficiency and economy of wind power there may be great question as to the best means of utilizing it. It was found on trial that the wind wheel was so often wrecked in violent storms, and wheels were constructed of such a nature as to partially close when the force of the wind reached a certain point, and thus diminish the resisting surface. The rudder has also been pivoted in such a way as to automatically turn on one side during a violent wind, and thus bring the wind wheel with its side instead of its face to the gale. Great numbers of machines, working on one or the other of these plans, are now in use.

In any such wheel there are several moving parts exposed to the weather, and the number of parts is also a disadvantage. If wheels with fixed fans and rudders could be safely used, they would of course be preferable, on account of their superior simplicity. This has been rendered possible by a plan of making a wind wheel compress air, which is then used to force water as required. The crank meets an elastic resistance at each stroke instead of the solid shock communicated from the piston of an ordinary pump and the weight of a long plunger rod is also dispensed with, as the air pump is fastened directly unto the casting that supports the wind wheel. This form of mill, as made by the Hartford Pump Co., is shown in Fig. 1 of the accompanying engravings, where it is represented as pumping water from a spring at a distance. From the air pump the compressed air is conducted through a half inch iron pipe (common gas pipe), any necessary distance, to the automatic pump, Fig. 2, which is submerged near the bottom of the well, and this pump, where the compressed air does its work, is the principal feature of this apparatus. Any other motive power may be used to compress the air, but no other pump can use the air advantageously when it is compressed. The following description and the cut will give a clear idea of its construction and mode of operation. It consists of two submerged cylinders or water chests fastened to and resting upon a frame which forms the bottom, and in turn rests upon a pivot, giving the chests a certain amount of vertical motion, say three or four inches. Each cylinder has in the bottom a valve opening upward to admit the water, and also at the bottom on the inner side a discharge pipe for the water. These discharge pipes unite in a common upright main.

Attached to the chests at the top, and directly between them, is the air valve, *A*, which determines the passage of the compressed air alternately from one chest to the other. The connection of parts is such that by a very simple arrangement this valve is operated by the rise and fall of the water chests, as will be seen by reference to the cut. The compressed air is always directed into the lower chest

When a certain amount of water has been expelled the chest is lighter than the opposite one and has a tendency to rise. When this tendency becomes sufficiently strong to overcome the resistance of the lever which operates the valve, the chest rises, the valve is changed and the compressed air is instantly diverted to the opposite chest, which now occupies the lower position. The valve at each motion opens a suitable escape for the compressed air which has already raised its bulk of water, and so allows the chest just emptied to refill through the valve in the bottom. The pump being entirely submerged, is non-freezing; the water pipe should be taken out of the well below frost depth, and the well should be kept covered in winter. Fig. 3 represents a section through the air valve and shows how the air passes in the different positions of the valve.

The operation thus described in detail is, in practice, extremely simple and certain. In the water chests the compressed air takes the place of a piston, thus saving the friction which necessarily exists where a piston moves in a cylinder and its rod through stuffing boxes. The application of power as variable as wind, through a perfectly elastic medium, is in itself a great economy.

The various parts of the windmill and pump are well made and durable, and the machine is little likely to get out of order or be affected by frost. The valves and valve seats are made of composition. All the wearing surfaces are turned and bored, the primal boxes are babbited and provided with self oilers, which keep all the parts well lubricated. The windmill can be placed several hundred feet from the well if desired, or if necessary to secure good exposure to the wind. The agent informs us that one machine in actual operation has the windwheel and air pump over a quarter of a mile distant from the automatic pump, and in this case the water is carried still farther and lifted 65 feet. This is a very decided advantage, as springs are usually situated in valleys where a windmill could hardly be placed to work with power and regularity unless perhaps in a lofty tower.

Fig. 1. HOUSE, BARN, SHEDS, ETC., SUPPLIED WITH WATER FORCED UP BY COMPRESSED AIR.

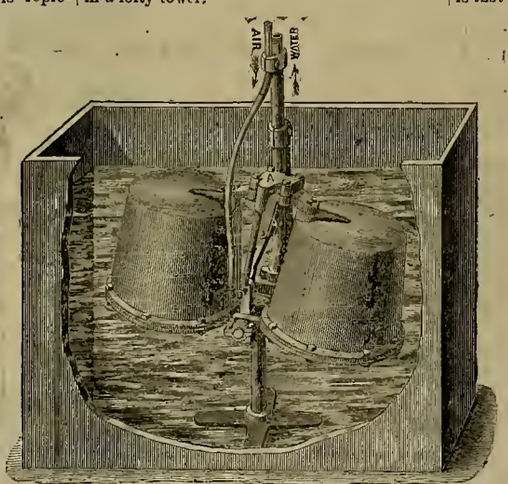

Fig. 2. Automatic Pump of Hartford Pump Company.

Fig. 3. Section Through Slide Valve.

The absolutely silent working of the apparatus is a great point in its favor, as well as the fact that, though the windmill is not "self-regulating" in the ordinary acceptation of that term, it nevertheless is so strongly made that the most violent storms, except such perhaps as might unroof the barn upon which it stands, have no other effect upon it than to make it pump the more. No rapidity of pumping can cause it to suck up gravel and so derange the pump, as windmill pumps so often do. It is necessary to oil it once a month, and this is probably all the attention it requires.

One would imagine, after seeing this apparatus in operation, that each country residence should enjoy the same advantages as to water as city houses. Every one is satisfied that if water has constantly to be drawn by pumping, or still worse, by more primitive arrangements, an injurious economy in its use is always the result, and that this is especially the case on farms, no one will doubt. A mechanical way, therefore, by which plenty of water can be raised in a reservoir not only from a neighboring well, but even from a distant brook, so as to save cattle the daily journey through all kinds of weather is a desideratum which especially stock-farmers appreciate. This apparatus can be seen in operation and examined in detail at No. 31 Beale street in this city, at the office of J. E. Holloway, general agent for the Pacific States.

Antimony.

Every month or so we receive letters from persons who have found large bodies of antimony ore, who desire to sell the mines here or deliver the ore. Almost every one of these persons supposes he has something few others have and consequently expects something big out of it. We have mentioned the fact a number of times that the market here is limited for this class of ore, and that only that of a certain percentage is bought at all. A great deal of the ore which is found falls below the marketable average, and is of no use. In other cases the mines are situated at a distance from railroads, and cannot therefore compete with mines which have good facilities for transportation.

The lowest grade of ore saleable in this city is that containing 50 per cent. antimony. Below that it is worthless. The lowest grade that will pay to be shipped to England is 60 per cent. The value of this ore, according to percentage, in this market is as follows:

50 to 55 per cent	$40	per ton
55 to 60 "	42.50	"
60 to 65 "	45	"
65 to 70 "	50	"

These are the prices given for ore delivered here sacked and sampled. It must have been properly sacked and properly sampled before it will be bought. The sampling costs from $2.50 to $5 per ton and the sacking according to how it is packed, so these expenses have to be taken into consideration by producers.

The market, as stated, is limited and liable to be glutted at any time, which frequently happens. So far as we know, no very large fortunes have been made from antimony as yet, although perhaps within a few years a better market for the product will be found.

THE Placer *Herald* says: There is talk of transferring the contract for the completion of the Nevada County narrow guage railroad to other parties.

Our Home Industries.

Bridge Building.

The rapid advance made in the civilization of the interior counties of the Pacific States has rendered necessary the construction of bridges to span the multitudinous streams which wend their way to the seaboard. The inestimable qualities of iron in the construction of bridges has been acknowledged to be chief among the essentials that go to make up a solid, convenient passage over streams; but the heretofore, and still existing, high price of iron in adaptable shape for the purpose, has caused science to examine into the utility of less costly material, and led ingenious men to devise such methods as to equal, in many respects, the greater tensile qualities possessed by bridges constructed exclusively of cast or wrought iron. While cast iron is remarkable for rigid, inflexible nature, wrought iron becomes superior on account of toughness. A number of such bridges now span our streams, but their value, in point of cost, makes them not only undesirable, but impossible to be employed generally.

In order to remedy any deficiency that may exist in the want of metal, wood has been employed in the construction of bridges with such success as to make the want of iron a matter of no great moment, with exception of where wide rivers or streams are to be spanned, and when the span must possess great tensile power or ability to bear the weight of innumerable tons. On the Pacific coast no greater success can be instanced than that exhibited in the patented wooden structure, controlled by the Pacific Bridge Co., of this city. We allude to the "Smith patent truss bridge," which is composed almost exclusively of wood and adapted to the span of wide streams. This bridge is capable of forming a span varying from 230 to 275 feet, perfect safety demonstrated by numerous practical tests, and capable of resisting the load of one ton to the lineal foot. As every locality, and object of bridge, suggests to the engineer the condition of its practical working capacity or power to uphold the passage of heavy weights, so the character of the bridge we name is determined according to the span necessary to unite two divided objects or divisions of land.

The Smith patent truss bridge possesses the requisite tensile qualities as well as those of an æsthetical character. The latter is only secondary, as the utility of the bridge to span wide streams is the main object, and the cause that can be assigned for the superiority of this bridge over all similar wooden structures on the Pacific coast. In almost every county in California, and also in Oregon, this bridge may be seen in different lengths and widths, every instance of them affording corroboration of their superior nature. The company possesses the sole right of the bridge named on this coast.

The Pacific Bridge Co. was organized at Oakland in 1872, under the efficient Mr. W. H. Gorrill as President, and Mr. C. H. Gorrill, Secretary and Treasurer. The business increased so rapidly that a removal of the office and works shortly after to this city was deemed necessary. The sphere of this company's operations increased wonderfully and until they extend to the manufacture and building of wooden and iron bridges, wharves, gates, dams and all kinds of heavy framework. Also sole agents for Smith's patent truss bridge, Klog Iron Co., Cleveland; Smith's iron combination bridge, of Toledo, Ohio, etc. The works are located at the corner of Fourth and Berry streets; office, No. 606 Montgomery street, in this city.

The company employed the last summer on an average upward of 250 men, in the several occupations we have named. One of their late works was the construction of the Oakland brick sewer, which has been pronounced by competent engineers equal, if not superior, to any similar work in the United States.

This company has at its head gentlemen of practical knowledge, skill and efficiency to devise means for the successful accomplishment of any work rendered necessary by circumstances, and where such necessity becomes obvious. Such are Mr. C. H. Gorrill, President, and Mr. R. W. Gorrill, Treasurer, whose wide practical experience in the art and comprehensive knowledge regarding works of the character named, is attested in the performance of some of the most difficult undertakings ever accomplished on the Pacific coast.

WORK on the stamp department of the California mill, on F street, Virginia, is being prosecuted with the greatest activity, and it is expected that it will be in running order by the 10th of January, 1876.

Lower California Mines.

In speaking of the mines of Lower California the Los Angeles *Express* says: "The Minerva mine is situated about three miles from San Rafael, the Pueblo and Trinidad both being about two miles from the town. A splendid natural road, with good grade all the way, leads from these mines to the town of San Rafael and to the bay of Ensenada, rendering the importation of machinery and supplies very convenient and inexpensive. Plenty of wood is in the neighborhood, and can be placed there for $5 per cord. A large and perennial stream of water is also within three miles of the mines.

The Minerva vein has been penetrated by tunnels to depths varying from 50 to 90 and 125 feet. The vein varies in thickness from eighteen inches near the surface, to five feet at the greatest depth mentioned. Over $50,000 have been taken out of this mine from year to year by the Mexican process of hogging it and working it in rude arastras. The vein is between granite and slate, and a fair average of the rock, from repeated impartial tests, gives $56 to the ton.

The Trinidad has been found to be immensely rich in pockets, and has been tunneled to a depth of 140 feet. By the same methods described above, upwards of $70,000 have been taken from this mine. We have ourselves seen a five-pound specimen of the ore, which contained upwards of $100. Single pockets have been struck which contained $20,000.

Pueblo, which is probably the best and most reliable of all these mines, has been penetrated to a depth of 225 feet. At that depth the vein is about three feet wide, and it yields an ore which averages $80 to the ton. There is abundance of ore in both the Minerva and Pueblo, with the chances of very rich returns on small outlays in the Trinidad.

Owing to the peculiar method of working these mines adopted by the Mexican population, there are easily 5,000 tons of ore lying outside the mines, which may be relied upon to yield, on milling, from $25 to $40 per ton. Working the mine with the disadvantage we have described, these persons worked only the richest ore.

The mines described have been inspected by a number of experts, amongst others by Jerry Miller, who was sent there some time ago by Mr. James A. Pritchard. Miller pronounced them excellent, and the facilities for working them admirable. The same judgment was pronounced upon them by Ferguson, another noted expert, and by an expert sent down to examine them by the Messrs. Frontier, Belmont and Bosch. And last, but not least, they are heartily endorsed by our informant.

The latter understands the present status of the mines to be that the Minerva, Trinidad and Pueblo have been consolidated by a San Diego company, of which Capt. Wm. A. Winder is President, A. B. Hotchkiss (District Attorney of San Diego county), Secretary, and Father Antone D. Uhach, Vice President. The Messrs. Gatewood, Hanlon, and others of San Diego, are the trustees. He learned that they are about to effect a lease of the mine to some heavy San Francisco capitalists, reserving to themselves one-fifth of their gross yield as a rent. We are glad to learn that these rich deposits will be made to add their quota to the circulating medium of the world, which they are so richly capable of doing.

DANGERS OF HYDROGEN TOY BALLOONS.—The Abbe Moigno calls attention to the need of placing restrictions on the sale of the miniature balloons inflated with hydrogen, which have lately appeared as a novelty in the Parisian toy shops. The case of a cabman is instanced, who was very severely burned about the head and eyes, by an explosion inadvertently caused while reaching into his vehicle, by placing the end of a lighted cigarette near to one of these balloons that had been left therein by a child. —*Les Mondes.*

AMERICAN PLATE GLASS.—The production of plate glass, but recently introduced into this country, is making very rapid progress. There are now three polished plate glass manufactories in the United States—one each at New Albany, Ind., Louisville, Ky., and St. Louis, Mo., and one rough plate glass factory, at Lenox, Mass.

THE *City of Peking* has gone into the dry dock at Hunter's Point to carry out the strengthening process. It is said that the company have engaged the dock for six weeks for her and probably other of their vessels.

It is said that there is more Orange county butter sold in New York, than could be made in that county if it was as large as the entire State of New York.

THE stamp mill of the California mining company will go into operation about the 10th of January next.

AN engineer from the Black hills reports gold at twenty cents a cord and bread at eleven dollars a crumb.

THE *Coso Mining News* is the name of a paper which has been started in Darwin, Inyo county.

A BILL will be introduced in the legislature for the suppression of quackery.

DEWEY & CO.

American & Foreign Patent Agents.

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chili, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advise of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, hook, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

OF INTEREST TO

MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practiced in projecting and constructing mining and milling machinery, and especially *machinery for mechanical ore concentration*, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

WATTERSON'S

Improved Chisel.

The Improved Chisel here illustrated was recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency. The improvement is adapted to all CHISELS FOR MACHINE OR HAND USE. The improvement consists of a Chisel in two parts, as shown in the engraving.

For Machine Use

We use TWO STEMS. From one-fourth inch to one-half inch, use one-fourth inch stem. For all Chisels from one-half to one inch, use one-half inch stem.

For Hand Use

Use from THREE TO FOUR SOCKETS (or upper portion) for a set of Chisels.

bility of mors where it cams from.

THE PHILIPSBURG SILVER MILL.—From J. A. Viall, who returned from Philipsburg last Saturday, was gathered some interesting information conceroing the Philadelphia compsny'e works. Ths Cols Sannders mill has bsen torn down snd ths sngine is being nsed for hoisting pnrposes on the mine. A nsw building has been ersoted, and sxtensive machinery has been snbstituted, and, although the sams procese of rednction will bs continned, maoy valuabls improvements and changes have been determined upon, whils the capacity will be greatly increased. In abont three wesks the mill will he entirely completsd and running again. In the meantime, mnch valuabls ore is being taken out of the mins.

Oregon.

JAMES GORNON MINE.—*Bedrock Democrat*, Nov. 17: This mine is sitnated about 5 milss east of Baker City, and about 4 miles west of ths Virtue mins. Thers has been considerable work dons hy the partiss, residents of our city, who own ths qnsrtz lsdge; thsy have a shaft sunk to ths depth of 80 or 100 ft, well timbsred. A short time sincs they had 70 tone of average rock from this mins worked in ths Virtue mine mill, snd sent ths bnllion to San Francisco to be minted. On last Monday thsy received tbeir retnrns, and found that the 70 tons of rock croshed yielded them the nics little sum of $1,844, or at the rate of $26.34 to the ton. Ths owners ars well satisfied with their mine, and will continus to improve and work it. The lsdges, as a general tbing, in this county, as thsy are opened and devsloped, are proving themselves to bs richer than first appearances indicatsd.

ROBERT EMMET MINE.—Ths ownsrs of this mins, John Toy, Patrick Faulknsr aod Gsorge Crocker, had 10 tons of thsir rock crushed in the Virtue mine mill, and the bullion recsivsd as ths rssult is worth about $200. We havs seen it, and tbiuk it will go ovsr that figurs; this is a yield of $20 per ton of top rock. As thsy havs wsnt down on the lsdge the rock preseuts a hettsr appearancs. Ths mins is very near and abovs ths Virtue. Ths opening of nsw mines near our city is progressing, and svsry appearancs is that Baksr City is locatsd in ths center of one of ths richest mining districts oo the Pacific coast. The futurs prospects of our city ars bright and encouraging.

SUMMIT MINE.—Mr. Morgan Ksltnsr, supsrintsndsnt of ths Summit mins at Hogsm, about 35 miles from our city, called on ns ysstsrday. He informs ns that thsy now have a shaft down on ths vein of qnartz, that ths lsdgs is abont 3 ft wids, ths rock looks well, and that crushed in the mill yisld at the rate of from $12 to $15 per ton. Tnsy havs a 10-stamp mill in connection with this mine, which is run by stsam; it will bs put to work crnshing rock this winter, and we sxpect to hear good returns from this mins.

Utah.

BINGHAM.—Cor. Salt Laks *Tribune*, Nov. 23: Ths mine ownsrs ars wrathy, ths ors bins ovsrflowing, and ths tramway company nnable to get the ors away. Should this thing last much longer, soms of ths minss mnst shut down. Even now ths Spanish and Jordan ars discharging men, their closing down altogethsr bsing only a question of a few days. Ws ars now producing 200 tons daily, 150 tons of which conld be shippsd by rail; but ths railroad company having, as I am informed, only ssven mules on ths tramway, cannot possibly ship fifty tons daily. This is ths time for tsamstsrs to wads in, as tbsre ars about 1,000 tons of ors to work on, aod the tramway a comparatively dead lettsr for ths winter.

STAR DISTRICT.—The Shumar smeltsr startsd up on the 10th iust., and in ons shift run out 180 bars of bullion. All the machiusry is working finsly, notwithstanding soms of it was damagsd by tbe lats fire. Evsrything bids fair for a successful rnn. I understand that orss of a smelting character ars to hs shipped from Piochs to this furnace for rednction. I venture the saying that there is not a neatsr and more complete fnrnace of its size now in Utah tban this. All ths minss look well, especially ths Bnrning Moscow, owned by Taylor, O'Nsil and othsrs. This is a large mine, and the ores, I understand, are bscoming of a higher grads than they have been. Other prospects are being worked and ths orss sent to the smelter for reduction.

CAMP FLOYD.—For some time past the mill here has been run on tailings bslonging to ths Camp Floyd silver mining company (hmitsd) of London, under tbe supsrvision of Mr. H. E. Miller, formerly of Tintic. To-day the batteriss were turned loose on ore from the Elkhorn, a mine belonging to the Qusen of the West company, and managed by Thomas Bsnnett, who is also manager of all the work carrisd on by the Qusen of the West company. This company have this mill nnder lease from the Camp Floyd company, and I understand thsrs is a strong probability that the first named company will purchase the mill. Ths mill contains an sngine of 100-horss power, sight amalgamating pans with four sttlers, and is said to be the fiuest mill in the Territory, though tbis might bs disputsd by othsr mill owners.

AT Ophir, Placer county, thsrs is a locust tree in inll bloom, which is as much of a rarety this time of the year as gresn wheat in full head.

A COAL vsin three inches thiok is rsported as having bseu strnck in the Sutro tunnel.

The Emma Mine Again.

Ws havs rsceived from London a copy of the directors' report on ths famous Emma mins, in Utah, which presents a very gloomy prospect for ths sharoholders sver getting their money back, although snit has bsen commenced against ths vendors. In thsir report the directors say:

"Shareholders ars aware that ths mins was seized nnder attachment by Park at the time ths action against hm and others was tsken, and that it hss ever sincs remained vestsd in ths United States marshal (sheriff); conssqnently the directors ars unabls to report as to any explorations, and havs no reason to suppose that any discovery of ore would havs besn mads had such explorations besn nndertaken; on tbe contrary, very voluminons reports from independsnt sources induce them to believe that the mine itsslf is, and has long been, utterly sxhansted. The only available source of incoms that conld have accrusd to ths company, and that only to a very limitsd sxtent, would havs arisen from the conoentration of the "fillings" or low grads ors lsft from former workings. Advicss rscsntly to hand state that Mr. Park under his attachment had sold the personsl property of the company—*i. e.*, the whole of the machinsry, plant, timber on surface, ths ors sacks, office furniturs, etc. We havs sent out instructions to pay off the Salt Lake sstablishment, and measures are in progress for a furtber reduction of expensss at the London offics by ths retirement of ths sscretary, stc. Mr. Attwood, ths general mauager, has rstnrned from America; hs will be prssent at the meeting; his report accompsnies this. The cass agaiust ths vendors is being vigorously proceeded with, and svidencs has bsen collected in this country from ths officers of ths company, ths promotsrs, solicitors, trnstses, stock brokers, ors brokers, accountants, bankers, all the English origiual dirsctors, and the American ambassador; testimony has also been taksn at Salt Laks City by commission. Ths rssult of ths svidsncs has, in the opinion of the company's legal advisers, tended to strengthen ths claim of ths company against ths vendors, and the cansss are already sst down for trial in ths Unitsd States circuit court. Facts have also come throngh the lats commission in England to the knowlsdge of ths board which havs indnced us, nndsr tbe advics of our solicitor, to apply for ths restitntion of monsys received hy certain of the original directors. The solicitor has prepared a rsport npon the commission, which report, and the opinion of counssl therson, will bs in our hands to be dealt with as the forthcoming meeting may dstsrmine. The directors havs no desirs to remain in offics, and will resign thoir seats at ths mesting on Novsmber 10th."

Ths report of ths managsr, Mr. Gsorgs Attwood, is also discouraging, as were his prsvions rsports. Hs tells in detail how hs sxtended his drifts, stc., without finding aoy ors. Hs says: "The fillings and scrapings still remaining in ths mins ars not yst all worksd ont, but it is almost impossibls to form an accnrate opinion upon sithsr ths qnantity or qnality of the same. Taking a rough sstimate, I should think yon have abont 4,000 tons in the mins of poor wasts, stc., that should yield by concentration 350 tons of ors, assaying thirty-fivs psr cent lsad, and ssvsntssn ounces of silvsr to tbe ton of 2,000 ponnds. Estimatsd gross valne, $30,000. Second class dump: Thers is still remainiug on tbs "dump" abont 100 tons of ths "original dump," and about 150 tons that has bssn mined nndsr my managemsnt. Estimatsd gross valns, $3,200. Condition of mine: Ths pressnt condition of ths mine is a most deplorable ons. The watsr having rissn within fifty fset of lsvsl No. 1, and remaining thsrs a greater pare of the snmmsr, it has now receded to abont twenty feet abovs lsvsl No. 4. Ths resnlt is that tbs timbsrs have givsn way in all directions, and sven ths engins shaft cannot be considsred safe to work in. It will now bs a most difficult as well as a dangerous and expensivs piscs of work to mins what fillings, waste and scrapings still remain. The greater portion of the old workings above level No. 1 has "caved in," and made an immense hole on ths surfacs, extsnding for 300 fset in length, some thirty feet in width and forty feet in dspth, exposing the "slide" shown in ths "gsological diagram" which accompanied my last rsport, in a most remarkabls manner; as the slide comes up within a foot of the surfacs the whole distancs of 3,000 fest, aud stands psrfectly solid, and all the grounu on the lower or southwest side has fallsn away from it, and is rapidly filling np the old workings abovs lsvsl No. 1. The Salt Lake office has bssn abolished, aud ths servicss of all the employses connscted with the same have bsen disposnsed with. I have now only two men employed at the mine to watch ovsr your interests there."

In conclusion, Mr. Attwood says: "I may say in conclnsion that my first rsport on our mins was made in March, 1873, and was an nnfavorable one, that my second report was made in May, 1873, and was even more so, and that my third rsport, mads in April, 1874, was squally nnfavorable. Since the last was written, I havs had sixteen months' forthsr time to examine into the geology and stratigraphical featurss of Emma hill, in rsgard to the future prospects of yonr mine, and from my numerons carefnl observations on the snbject, I can only reiterate what I have statsd in my previous reports, that is, that yonr mine is virtually exhausted, and that yonr only hops for the future rests sntirely on solving a geological problem, which problem will take time, a large snm of money and skillful engineering to solve."

Rain Table.

By this kindness of Dr. T. M. Logan, ws are snabled to lay before our readsrs a rain table completed and brought down to the nearest possible dats available for our prssent issne.

RAIN TABLE FOR SACRAMENTO.—PREPARED BY DR. T. M. LOGAN.—FOR THE PRESS.

Arranged according to the seasons, showing the amount in inches of each month, during twenty-seven years, and for each rainy season, to November 20th 1875; also the quantity for every month, and the annual amount of rain.

THE new air machinery in ths Bullion mine has greatly cooled the drifts, and is fast makiog ths lower lsvels of the mine just as comfortable for working pnrposss as the npper. So far the new plan is a complete snccsss.

THE rain has startsd tbe plow in every portion of the State excspt the low lands, where it is too wet to plow. Every indication as far as the wsather is concerned points to an abundant harvest next season.

SAYS the Downieville *Messenger*: At the bottom of a seventy-foot shaft in a qnartz mine near Forest City, last week, ths boys struck a bank of solid gold. That qnartz stock is not for sals.

A DIFFICULTY occnrred between two miners, partners, at Montezuma, Tuolumne connty, recently, in refersnce to the sale of a mining claim, when one knocked the other down and kicked him, cansing dsath.

AN itsm is going the rounds of the press to the effsct that artesian well-borsrs in Tnlare have discovered a vein of gold-bearing qnartz at a depth of 258 feet.

Physicians are wonderstruck at the cures of obstinate coughs, violant colds, difficulty of breathing, and incipient consumption,, daily accomplished by HALE'S HONEY OF HOREHOUND AND TAR.

Pike's Toothache Drops cure in one minute.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

THE CAPITAL QUICKSILVER MINING CO.—November 24. Location: California. Directors—Wm. A. Hutchinson, George H. Bell, Edmund Lane, Marcus E. Austin and David A. Brown. Capital stock, $5,000,000, in 50,000 shares of $100 each.

PACIFIC LAND AND IRRIGATION CO.—November 24. Capital stock, $500,000. Object, conducting water from the Upper San Joaquin and other streams in Fresno county, for irrigation. Directors—William Applegarth, D. G. Bartlow, Frank Drake, Laverne Barris and Clement C. Barris.

OAKLAND AND CONTRA COSTA RAILROAD CO.—November 20. Among the incorporators are General T. H. Williams, Hon. John P. Jones, J. Walker and Mr. Mackey. A saving of six miles will be effected by the building of the road, which will take the following course. From Alameo for a mile west, through a pass in a low range of hills to the head of Tice valley, one-half mile from Alemo. Thence about a mile to Judge Daniel Hunsaker's old place. Thence westerly to the "Calf ranch," three-fourths of a mile. Thence three-fourths of a mile, connecting with the old road at or near the place of David Carrick—following the course of that road a mile and a half to the old store in the Moraga valley. Thence westerly across an easy range to the old Redwood pass road, and so on to Oakland.

JERSEY M. CO.—November 28. Location: Humboldt county, Nev. Capital stock, $1,000,000. Directors—W. Hamilton, E. J. Swift, W. O. M. Berry, Archie Borland and J. A. Blossom.

SELBY HILL M. CO.—October 30. Location: Nevada county, Cal. Directors—H. H. Pearson, J. F. Sweeny, T. C. Lanyee, J. C. Bateman and Romualdo Pacheco. Capital stock, $1,000,000, divided into 40,000 shares of $25 each.

RED CROSS CONSOLIDATED G. & S. M. CO.—Oct. 30. Location: Virginia District, Nev. Capital stock, $10,000,000, divided into 100,000 shares. Directors—Henry S. Fitch, Silas Selleck, Henry F. Morris and William C. Quirey.

WHITE CROSS CONSOLIDATED G. & S. M. CO.—October 30. Location: Virginia District, Storey county, Nev. Capital stock, $10,000,000, divided into 100,000 shares. Directors—Henry S. Fitch, Silas Selleck, Henry F. Morris and William C. Quirey.

ROSECRANS G. M. CO.—Oct. 27. Location: El Dorado county, Cal. Capital stock, $640,000 in 64,000 shares. Directors—Anther S. Peterson, Edgar Blebop, Samuel J. Corbett, Henry W. Russell, Nathen D. Bnrlingham and D. W. Fox.

ALLISON RANCH FRANKLIN M. CO.—Nov. 1. Location: Allison Ranch, Nevada county, Cal. Directors—Edward Commins, John Harrold, Cornelius O'Connor, Patrick Rogers and Martin Ford. Capital stock, $1,800,000, divided into 25,200 shares of the par value of $40,000.

NEVADA SULPHUR M. CO. — Nov. 1. Location: In the Rebbit Hole Range, and especially in the McWorthy sulphur claims, in the county of Humboldt, Nev. Directors—C. Mitchell Orant, G. J. Giling, F. J. McWorthy, Henry W. Wymon and W. S. Campbell. Capital stock, $1,000,000.

STERLING M. CO.—Nov. 1. Location: Eureka district, Eureka county, Nev. Capital stock, $5,000,000, in 50,000 shares of $100 each. Directors—Adam Hall, Wm. Arrington, George F. Bragg, John Chamberlain and Stephen Roberts.

SUTTER CREEK, February 26th, 1875.

MESSRS. DEWEY & CO.—I have received my Letters Patent through your Agency. nd, for your prompt ness, accept my thanks. Yours, S. N. KNIGHT.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THARP—San Francisco.

B. W. CROWELL—California.

A. C. CHAMPION—Tulare, Fresno and Inyo Counties.

JOHN ROSTRON—California.

A. C. KNOX, California.

G. W. MCGREW—Santa Clara county.

CHAS. T. BELL—California, Oregon and W. T.

D. J. JAMES—Australian Colonies.

CHAS. T. BELL—Montana, Utah, Idaho and Nevada.

SUBSCRIBERS are requested to examine the printed address on their papers. If mistokes occur *at any time* please report them to this office. The last figures (at the extreme right) represent the year that your subscription is paid to. Next to these the day and month is expressed. For instance, your subscription being paid to July 4th, 1876, it would be represented, viz: jl 4 76; or 4|7|6.

THOUGHTLESSNESS.—Persons sometimes return their paper, marked "stop this paper." Their name being pasted on the sheet they think thet is all we need to be able to cross their nomes off. Now that is thoughtlessness. Your P. O. address is needed as much as your name. We have thousands of names arranged only according to locality. Our mailing clerk does not know whore everybody lives.

GIVE YOUR FULL ADDRESS when you communicate on business to this office, especinlly in returning newspapers. The fact thet your nome is on our subscription list is of no assistance to us. Without sending your post office address we should have to look over thousands ofnames to find yours.

Mining and Scientific Press.

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi.

As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Miners, Assayers, Milliman, and Metallurgist in the United States should take it.

Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columne of fresh and valuable information.

Mining Engineers, Superintendents, Metallurgists, Mine Owners and Mine Workers throughout the world should profit by its illustrations a de descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughont the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE,

DEWEY & CO.,

No. 224 Sansome street, S. F

MESSRS. DEWEY & Co., San Francisco:—Please find enclosed post-office order, for which please send MINING AND SCIENTIFIC PRESS. I have been a close reader of the PRESS for three years, and regard it as the foremost mining periodical in the Union. I am glad to notice the circulation of the PRESS is increasing here and is highly prized by our best mining men. H. P. Central City, Colorado.

At a Stated Term of the Circuit Court

of the United States of America of the Ninth Judicial Circuit in and for the District of California, held at the court room in the city and county of San Francisco, on Thursday, the 30th day of September, in the year of our Lord one thousand eight hundred and seventy-five. Present—The Honorable Lorenzo Sawyer, Judge.

Nicholas Seibert, complainant, vs. Wm. T. Garratt, defendant—In equity.

DECREE.

This cause came in to be heard at the February Term, A. D. 1875, of this Court and was argued by counsel and thereupon upon consideretion thereof, it was ordered, adjudged and decreed, as follows, viz: That defendant, William T. Garratt, was not the first or original inventor, or discoverer of the improvement or discovery claimed by him, in and by those certain relesued letters patent of the United States, number five thousand three hundred and twenty-eight (No. 5328), for an alleged new and useful improvement in lubricetors, issued to said defendant, William T. Garratt, on the 18th day of Merch, A. D. 1873, and is not entitled to a petent therefor, and that said relssued letters patent, number five thousond three hundred and twenty-eight (No. 5328) are declered void and the same are hereby vacated and set aside by reeson of their interference with these certain lettors patent of the United States, number one hundred and eleven thousand eight hundred and eighty-one (No. 111,881) for a new and useful improvement in lubricators, issued to complainant, Nicholas Seibert, on the fourteenth (14th) dey of February, A. D. 1871.

It was also further ordered, adjudged and decreed that complainant do have and recover of and from defendant his costs and expenses to be taxed herein.

(Signed) LORENZO SAWYER,
Circuit Judge.

The above decree bas reference to "Seibert's Eureka Lubricator" for oiling the valves and cylinders of steam engines.

It has a glass gauge and condensing pipe, or reservoir, with a regulating feed velve, and works as follows: As the water of condensation is admitted, under the oil, just so fast the oil passes out at the top through a pipe into the steam pipe to oil the valves and cylinder.

Parties who infringe or purchase the infringed lubricators, will be held strictly responsible.

N. SEIBERT, Patentee,
125 First Street, S. F.

And in accordance with law, and an order of the Board of Trustees, made on the 23d day of October, 1875, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of the Company, room No. 11, 215 Sansome street San Francisco, on the 18th day of December, 1875, at the hour of 12 o'clock, M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

T. J. OWENS, Secretary.

Office, Room No. 11, 215 Sansome street, San Francisco, Cal.

Pioneer Fluming Company—Location of

principal place of business, San Francisco, Cal. Location of works, Shirt-tail Canon, Placer County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the thirtieth day of November, 1875, an assessment of five cents ($0.05) per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at 116 Leidesdorff street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the third day of January, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the seventeenth day of January, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. W. AUG. KNAPP, Secretary.

Office, 116 Leidesdorff street, San Francisco, Cal.

UNITED STATES

Mineral Land Laws, Revised Statutes,

And Instructions and Forms Under the Same.

We have just issued a pamphlet containing the general mineral land laws of the United States, with instructions of the Commissioner of the Land Office The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870 Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of $500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO.,

Publishers of MINING AND SCIENTIFIC PRESS, S. F.

THE MINING AND SCIENTIFIC PRESS is the leading journal of America. New processes and mechenical inventions are illustrated and discussed in its weekly issues. It is a 16-page sheet, handsomely printed, for $2 per year. Dewey & Co., publishers, San Francisco, —[Mt. Lincoln News, Alma, Colorado.

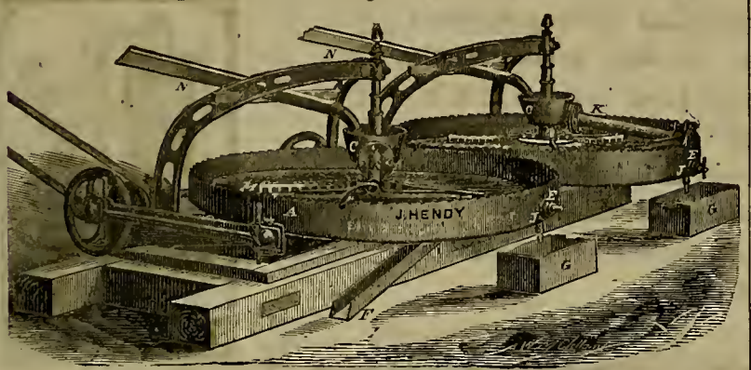
BY THE USE OF

Hendy's Improved Amalgamator and Concentrator



Can be seen at the Manufactory, No. 32 Fremont Street, San Francisco.

SAN FRANCISCO, April 27, 1872.

JOSHUA HENDY, Esq.—*Dear Sir:*—As a practical miner and millman, I take pleasure in recommending the use of your Concentrators in all mills where gold or silver ores are reduced. No mills should be without them, for the following reasons:

1st. They are good sizers (no perfect concentration in pulverized ores can be effected without first sizing).
2d. The best Concentrator I have ever known—(the concentrated stuff only containing 5 per cent. of sand).
3d. They are good amalgamators, light (feathery) particles of amalgam and particles of coated gold by attrition are brightened, and from their specific gravity and the action of the pan, fall to the bottom and adhere.
4th. They require but little power and attention to run them, and with ordinary care will last for years.

I have been familiar with the workings of your Concentrators for four years past; have run them myself in the North Star Mine, Grass Valley; am familiar with their practical workings on the Empire Mine, Grass Valley; St. Patrick, Placer Co.; St. Lawrence, El Dorado Co.; Oaks and Reese, Mariposa Co., and most cheerfully give you this testimonial. For further information you are at liberty to refer to,

Yours respectfully, JAS. H. CROSSMAN, M. E.

409 California street, or Cosmopolitan Hotel.

SAN FRANCISCO, February 10, 1874.

OFFICE SUPERINTENDENT OF KEYSTONE CON. M. CO., AMADOR, AMADOR COUNTY.

MR. J. HENDY—*Dear Sir:*—In answer to your inquiries as to your Concentrators furnished our company last July, I would say that I am more than pleased with them; and the saving to the company has been over $3,500 per month more than with the blankets and buddies formerly in use. O. C. HEWITT, Supt.

OFFICE SUMNER MINE, KERNVILLE, April 27, 1874.

J. HENDY, Esq.—*Dear Sir:* Having four of your Concentrators in use at our Mills for four or five months, which for saving Amalgam and for concentrating Sulphurets, are a success, beyond a doubt, I feel it a duty due you and those interested in Quartz Mills, to recommend them.

As further evidence of their worth, I now order TWELVE more of your Machines for our new Mill, now in course of erection. E. R. BURKE, Superintendent.

For description send for Circular.

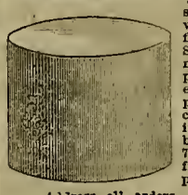
Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.



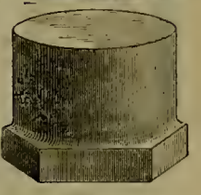
[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.



Address all orders, with dimensions, to W. R. Townsend, Secretary.

54 BUSHELS OF CORN AN HOUR.
HARRISON'S
LIGHT, VERTICAL BURR MILLS
BARBER & BACON, MILLERS AND LUMBER DEALERS, SOUTH VERNON, VT., write July 15th:
"We have been running two of your LIGHT VERTICAL CORN MILLS for the past 6 months with remarkable results, and have ground over 80,000 bushels of corn into No. 1 meal in that time, running the grist-mill nights only, as we run our saw-mill in the day time. We have often ground in the 20-inch Mill (which weighs about 500 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 24,300 lbs., or 434 bushels. To do this we have to run at a speed of 1,300 turns per minute, and use about a 20-horse power. You may refer parties to us for further information, and when we have tested your HEAVY VERTICAL MILL, we shall take great pleasure in giving the results."

Mining Superintendent

Of fifteen years' experience in working the most rebellious ores on the continent, desires employment. The gentleman thoroughly understands the opening and development of mines, and the construction of all kinds of machinery and appliances for the reduction of ores, and especially those termed rebellious, Can be communicated with through this office.

Important in regard to Pumps.

Aurora, Nevada, November 10, 1875.

H. P. Gregory & Co., San Francisco.

Gentlemen: I am exceedingly well pleased with the "SPECIAL PATTERN BLAKE MINING PUMP" and its workings; especially so with the "MORTON EJECTOR CONDENSER." Have both in position on 400 foot level. The condenser is doing all that is recommended, and is saving from one and one-half (1 1-2) to one and three-quarters (1 3-4) cords of wood per day, I consider it a very useful improvement.

Yours Respectfully,

Warren Rose, Supt. Juniata Cons. S. M. Co.

We are prepared to put in the "BLAKE IMPROVED STEAM PUMP" in connection with the "MORTON EJECTOR CONDENSER" and fully guarantee a saving of from thirty to forty per cent. over any other direct acting Steam Pump in use.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Patent Solicitors.

SAN FRANCISCO, SATURDAY, DECEMBER 11, 1875.

VOLUME XXXI Number 24.

The Triple Cylinder Engine.

We present herewith an engraving of a triple-cylinder, compoand balanced-piston steam engiae, invented by Farrelly Aldea, of Pittsburg, Penn. In this engine two cylinders alternately receive steam at each revolution, and alternately exhanst into en- anxiliary cylinder, common to botn, while these pistons are balancod by the circulation of the exhanst steam. The throe cylinders are in line with one stem, or for certain purposes are arranged parallel with three stems of locomotives, pumping and marine engines, whether vertical or horizontal. It is intended to utilize all the exhaust at high or low pressnra, with or without the aid of a condenser. The *American Manufacturer* speaks of the engine as followe:

The engine ntilizee all the exhanst, avoids all hack pressure and secures regular motion. To do this the high pressure oylinders are singla aoting, taking steam at one end only, and their pistons make the rotnrn strokes without back preseore, aa the exhanst circulates on both sides of them, thereby avoiding all back pressnre.

The low preesnre or anxiliary cylinder is donblo acting, and receives all the exhanst expansively from each of the steam cylindere alternately, while their pistons are balanced by the free circalation of the exhanst around them; consequently this utilizes all the exhaust steam.

There is a full force of steam carried to the end of each stroke in the alternate receiving cylinder, and the exhaust from the other high pressure into the anxiliary at the same time gives all the force of the steam and exhaust at each stroke; this secures regular motion. With less than three cylinders the motion at each revolution would be so very irregular as to be impracticable, as is proven by experience. This triple combination is adapted to all kinds of steam engines, vertical or horizontal, whether the cylinders are in line with one stem or parellel with three stems; and for stationary, locomotive or marine.

The great value of this locomotive to the world cannot be readily calculated, but it is sufficient that it saves half the fuel and half the boilers, or virtually doubles the power of steem, when compered with the common single cylinder engine. The steam navies will be compelled to adopt it, or become demoralized with an enemy's small swifter steamers esch cerrying a single gnn of long range to sweep the oceans of their commerce; and the commercial steamers cannot afford to be stripped of their carrying trade by the swift steamers of their more pregressive neighbors. Wherever fuel ia scarce and dear the superior merits of the Alden engine will be qoickly appreciated. It will stimulate the development ot onr vast mineral resources in the territoriee by furnishing steem power at half the present cost for fuel, and pnt into bonanzas thousands of valuable minee that are in borrasca.

Multitudes of cernest enquirers are daily witnessing the snccessful running of one of these engines (the first ever built) at the Pittsburg Tradesmen's Industrial Institute. It is of 12¾ inch cylinder, and with 75 lbs. of steam exerts a force of 93 horse power actual, with 2 ft. stroke and 50 revolutions per minnte.

The K. K. Strike.—The report that the K. K. Consolidated mine at Enreka had strnck a bonanza is trne. We have been shown a private letter from the superintendent saying that they had strnck a superb body of ore, commencing at the 5th level, continuing to the 6th and dipping below the 6th. The shaft is run down about sixty feet toward the 7th level. The mine is turning out from two-third new ore and one-third reserve dry ore, from ten to eleven and a half tone of bullion per day. The percentage of lead is very high, abont four tone of ore to one of bullion.

Owino to the extreme stormy state of the weather, but elow progress has recently been made with the erection of the new works on the Utah mine,

Alden's Ore Pulverizer.

We give on this page an illustration of a now ore pnlverizer, invented by F. Alden, 25 Fifth Avenno, Pittsbnrg, Pa. The cnt gives a sectional view of the machine in operation. Its vital parts are two vertical corrugated jaws, that swing or vibrate to and fro, while held together at the bottom hy a sliding yoke, so as to produce a donble rubbing, grating or filing motion at both forward and back stroke. It is regulated for coarse work of blast furnaces, stone breaking, etc., or down to dnst for gold or other ores. All sizes are manufactured to snit each kind of work. It is claimed that this machine will prodnce donble as mnch fine work as eny machine of the same weight, and when set at 3-16 inches prodnces 45 per cent. dnst to No. 12 siftings.

The nniform fineness of the ornshing or pnlverizing is regulated by set screws or liners, to make either coarse or fine work. The receiving ospacity is 14x7 inches, and if the discharge is set at one-fonrth of an inch and running at 150 revolutions per minnte, a 14,000 pound machine rapidly brings Lake Superior hard iron ore to a fix at one operation, reducing more than 4,000 pounds per hour, and 34 per cent. of it goes through a No. 18 wire sifter.

It is radically different in principle and construction from all other ore reducers, and is said to do its work better and more economically than both the stone breaker and rolls together. It differs from moet in use by having two movable jaws instead of one, and in redacing the substance fed by a file-like or rubbing motion instead of a crushing one.

Eight horse power is sufficient. Dimeneions —8 feet long, 5 feet high, 2 feet wide; the jaws,

ALDEN'S ORE PULVERIZER.

3 feet loug by 14 inches wide; the chilled rubbing diee, 360 pounds—total 14,000 pounds—all made ot the best materials, well proportioned and carefnlly fitted, nnder the direction of the inveutor.

H. M. Yerinoton, general superintendent of the Virginia and Truckee railroed, has been elected a director of the road in the place of A. M. Edgington, deceased, and also vice-president of the company, to fill the vecancy oaused by the resignation of A. J. Raieton.

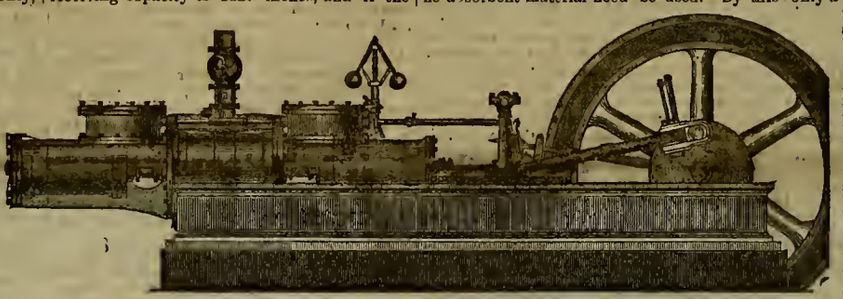
The Evening Star quartz mill, on Salmon river, in Siskiyou county, was deetroyed by fire on the morning of the 2d inst., at twenty minntes past one o'clock. No insnrance. The lose is between $8,000 and $10,000.

The bullion shipped from Austin in Novembor, according to the *Reese River Reveille*, on account of Manhattan silver mining company, was es follows: 116 bars, weighing 8,171 pounds, vslued at $108,415.31.

Notices of Recent Patents.

Among the patents recently obtained throngh Dewey & Co.'s Scientifio Press Amorioan and Foreign Patent Agency, the following are worthy of mention:

Ant Extbrminator.—Michsel Barthel, Milpitas, Santa Clera oonnty, California. The objeot of this invention ia to provide a box or oase, in which any oompound or snbstance for poisoning ants oan he kept in a properly moist condition to permit the ants to feed from it, and which is provided with suitable openiugs to admit the ants to the interior of the box, so that they csn feed npon the contsined substance or compound. Mr. Barthel makes a compound which he places in the bottom of the box. He then pleces a piece of sponge cotton or other absorbent materiel, which has been satnrsted with water, upon the mixtare inside of the box, and covers it over. The wet sponge will keep the mixture moistened and soft so that the ants can eat it. When the poisonous mixtnre is soft no absorbent material need be used. By this mesns any ordinary invasion of ants may be terminated in a short time.



TRIPLE OYLINDER COMPOUND BALANCE PISTON STEAM ENGINE.

Shinole Machines.—Wm. P. Valentine, San Francisco, California. This consists of improvements on a patent previously granted to the same inventor. The improvements are: first, an arrangement for adjneting the tilting frame or teble which shifts the angle of the bolts or hlooks after esch shingle is sawed; this sdjustment being for the pnrpose of regnlating the thickness snd taper of the shingles. Secondly, it relates to certain improvements in checking and stopping the receding movement of the carriages or sliding frames which carry the blocks from the tilting table to the eaw and bsck again. The invention slso includes improvements in operating the olamp or dog which alternately grasps and relesses the bolts or blocks when the machine is in operation. The machine can aleo be nsed for sawing out boarde for hoxes and eimilar purposes.

Harrow.—James B. Green, Elliott, San Joaquin county, Cal. This invention relates to that class of harrows in which tho harrow teeth are secured in two or more shafts, which extend transvereely across the herrow freme, so that the shaft or shafts cen be rotated in order to free the teeth from the accumulations of straw, woede or other obsteeles. This improvement consiste in the employment of certain devices by which these shafts are caused to rotate automatically and euccesively so as to free themselves of weeds and etraw. The teeth leave no nnharrowed spote in a field, neither will they rake the etraw or weede which they gather, into large pilee to be left on the field, but weods and etraw will bc left nearly in the aame position they occupy before the herrow passee over them, while the ground beneeth will be properly harrowed.

Bleaohino Soap.—Peter Burns, San Francieco. This invention is a new combination of ingredients for the manufacture of a soap for weshing and bleaching purposes. After adding the patented mixture to the soap, flavoring extracts are added in the nsual way. The soap is then allowed to stand aod harden, when it can be cut out or otherwise formed into bare. This snap possesses extreordinary cleansing qualitiee and the inventor says that when properly nsed febrics oan he cleaned with it without rubbing.

A. J. Doolittle.

The compilor of the "Map of Central California" (embracing the counties of Butte, Ynba, Nevada, Placer, El Dorado, end Amador), so well known to the readers of the Mining and Scientifio Press, was one of tho nnfortunate three hundred who went down with the steamor *Pacific*, on the 4th of November.

Not a trace even of his going aboard that steamer is on record; the only traces of tho three hnndred who with him left Victoria that Thursday are the pieces of the wreck, and a few bodies, which have drifted into the straits of Fuca, and are now strswn elong the heach at Beacon hill, Victoria, one hundred miles from the scene of the collision, which sunk both the oolliding vessels almost instantly.

Mr. Doolittle had despatched his bnsiness at Seattle with great energy, and deemed himself very fortunate in getting aboard the *Pacific*, only a few minutes before she sailed. His name was consequently not booked among the list of passengers. He visited Beacon hill three or fonr times while the steamer lay at Victoria on her homeward voyage, to call on a friend who had made his acqnaintance in the office of tho Press, whon the "Map of Central California" wes first brought to the attention of the pnblie.

Doolittle was a "character." He was honest, industrious, shiftless and full of ideas. His ideae were generally sound and full of merit. He traced the connections of the grevel deposits aud of the quartz belts of the counties named with much labor, and rudely indicated them on his map. The latter was drawn almost wholly by his own hand. The work, done hy one not a professional draftsman nor a geologist, reflects great credit upon him, having been for nino years past the principal standard of reference relating to localities and mines in the central mining region of California.

Mr. Doolittle had recently visited the coal mines at Nenaimo, Wellington and Seattle, to introdnce a new boring machine partly of his own invention. Up to the time of his nnfortunate trip to the North he was interested in and carrying on hydraulic mining operations at Liberty hill, Nevada county.

A great deal of the information on the Geological Snrvey "Map of the Vicinity of the Bay of San Francisco" was collected by Mr. Doolittle under a private contract with Professor Whitney. Mr. Doolittle also compiled and published a map of Homboldt county, Californiа, about 1863. He was a member of the Masonic Order, and highly respected for his manly honesty and intelligence by all who knew him.

A. B.

Mining Suit.—A complaint has been filed in the Fourth district court, in the case of Daly & Hawkins *vs.* J. M. English, John S. Magee and Arthur H. Hawkine. Plaintiffs aver that in December, 1874, Magee obtained a bond from the owners of the Gila mine, situated in the Reveille district, Nevada, for ite purchase price of $12,000, and plaintiffs were approached with the subject of becoming jointly interested with defendents in the enterprise, plsintiffs agreeing on taking one-quarter of the risk. Five thousand dollars was supposed to be the amount necessary to work the matter into proper shape, but before plaintiffs had been called upon for their *pro rata* of this amoont, a large body of ore was struck in the mine and defendents at once proceeded to incorporate the mine and dispose of shares without the co-operation of plaintiffs, who now claim $1,000,000 as their share of the profits of the transaction. They eliege that the markot value of their claim is $300,000. In addition to one-qnarter of the mine they sue for 25,000 shares of the capital stock, which they desire placed in the hands of a receiver, to be appointed by the coort.

R. M. Daggett, who for many years has been connected with the Virginia *Enterprise*, has retired from that peper.

A new fonndry has been started in Winnemnoca.

The Mineral Resources of Mexico.

In the Gold Hill *News* we find the following communication upon the mineral wealth of Mexico, which at the present time will be read with interest:

Having spent several years in the various mines of Mexico, at least in the northern part of it, comprising the States of Nuevo Leon, Chihuahua, San Luis Potosi, Zacatecas, Durango and Sinaloa, I will endeavor to give you some idea of the formation of the veins and the different classes of ores extracted from them, the mode of operating mines and the manner of milling employed in the haciendas or reduction works.

The veins can generally be traced on the surface, not by large rough croppings, but by a clearly visible formation of carbonate of lime, oxide of iron and iron ochre, often intermixed with green carbonate of copper, and distinguishable all the more as they are generally found in bedrock of blue or dark brown slate. Most of these veins are, from the surface down, possessed of such a wonderfully true underlay, that a tunnel to them can be calculated within a few feet to a certainty.

Nature of the Ores.

On the Eastern slope of the Sierra Madre, and through to the gulf, all silver bearing veins carry down to a certain depth a variety of ores, some of which are found in no other part of the world.

The most prominent are iodite and bromargyrite, or lode and brome silver. Both species are called "plata verde," or green silver, and are found in scales or small crystals of carbonate of lime of the aforemade description of croppings. This matter extends, in the district of Catorce, for example, down to a depth of 400 meters in Zacatecas, only fifty miles in Tresnillo, Mineral de Plateros 150 meters, showing pockets of the iodite and bromargyrite, as also of kerargyr, or horn-silver, the assays of which are often no less than from $400 to $500 to the carga of 300 pounds.

At the indicated depths the transition commences, being no less than fifty metres deep of vein matter of the description of the Comstock clay, iron pyrites being strongly prevalent. This transition very rarely carries metal, but if it does, nothing less than native silver. Now follows a vein matter which can be said to be almost like that of the Comstock, only that the appearing ores are silver ores pure, or a much finer grade than those found here. In the mine San Augustin, Catorce, there are no less that 500 tons of pronstite or ruby silver ore brought to the surface every week. The mine La Suz, in Zacatecas, produces that much and more of pyrargynite or antimonial silver ore, and pockets of fine silver are not unfrequently found giving from two to ten million dollars. But the

Imperfect Mode of Working

Leaves most of these treasures yet hidden in the mountains. Coyoting is the best name for it, working down with a crowbar until a little pocket is struck, eating out all the ore, then driving for another one—that is the general plan. Regular shafts are seldom thought of, because of the lack of hoisting machinery, the most complicated being four-horse power windlasses. Peones carry the ore on their backs to the surface or to the bottom of some shaft, and it is astonishing how these people take a weight of 200 to 300 pounds over ladders made of one log, through drifts which they have to pass on their knees, and up and down slippery steps where a fall would mean certain death. Their compensation is four bits a day, which suffices to keep them on beans and chile and furnish them Sundays with a quantum of mescal or aloe brandy, sufficient to make them unfit for work on Monday. The regular miners of Carretero receive $1 per day, but prefer to work on shares. This system of working on shares is an enormous loss to the mine, but cannot be dispensed with where you have miners who require a foreman each to keep them to work. The plan alluded to is simply to give the miner one-third, one-fourth or one-fifth of all ores brought to the surface in his name, each batch being dumped separately and divided, according to grade, into three, four or five parts, and the miner selecting his share. This mode has almost become a privilege, and the writer of this narrowly escaped lynching in trying to substitute day labor for this expensive system of dividing.

Drifting is done by contract altogether, one miner in the bedrock costing from $30 to $50, while on the vein it costs from $10 to $30 per metre.

The ores brought to the surface are, according to their assays, ranged into seven classes: "Especial," "Bonito," "Amarillo, 1 deg.," "Amarillo, 2 deg.," "Amarillo 3 deg.," "Millon, 1 deg.," and "Millon, 2 deg.," and in this order shipped to the

Haciendas or Reduction Works.

The transportation is done on mule or donkey back, large herds of these arriving every morning at the gates of the mine and leaving packed with 200 or 300 pounds each for the haciendas. This institution covers generally not less than ten to fifteen acres of ground, being surrounded by buildings and high walls, carefully guarded against intrusion. The ore is first broken to a small size, about as large as hazel nuts, by the "mortero," acted upon by a dozen or so hammers, which, by a very simple piece of mechanism, are raised and drop by themselves, four horses furnishing the motive power. From there it is taken to the arastras, of which some haciendas have as many as 100 going. Being well pulverized in these the pulp of all the oxides, bromargyrites and kerargyrs or horn silver is taken to the pans, where by pure mercury, together with stirring or gentle heat, the amalgamation is effected in eight hours. Low grade ores of the same class are taken to the patio. Here 100 to 200 tons are spread out in a large cake, with mercury; salt and sulphates of copper are added in proper time, and the whole of it worked through by mules and shuffles every few days for the time of about one month, at the end of which the amalgamation has taken place. All other ores, and principally sulphurets, are first roasted with salt, that is chloridized, and then undergo the same treatment as the former. The roasting furnaces are merely an open iron plate below which the fire plays, and the stirring is done by hand. All this will demonstrate what a large field there is in Mexico for enterprising mining and milling men. The country abounds in mineral wealth, but has as yet hardly passed the first stage of development.

The Golden Enterprise.

This, says a correspondent of the Plumas *National*, is the name of a new mining enterprise, inaugurated some time since by Mr. Richard Jacks. The claim is located on Spanish creek, a short distance from Spanish ranch. We had intended to pay this part of the country a visit for some time, and take a look at the mines, but have not been able to find time. An obliging correspondent gives us the following description of the new operation, and we gladly give it room. He says:

Among the many new mining claims about being opened, the Golden Enterprise deserves more than a passing notice. Situated on Spanish creek, about five miles west of Quincy, in a district that has been famous for its rich diggings since "early days," it will open up a vast country hitherto unprospected. The bedrock on what is known as Grub flat, is very deep, and all the mining which has been done in the vicinity has amounted to but little, as there was a layer of cement five or six feet from the surface, through which they were unable to sink on account of the water. One shaft was sunk through, and beneath the cement was found blue gravel which prospected very rich, but the water could not be kept out without machinery, which the parties prospecting were unable to purchase, and as there were good mines in the county which could be more easily opened, the shaft was abandoned.

Mr. Richard Jacks conceived the very sensible idea of going about a mile down Spanish creek, and bringing up a flume large enough to carry all or nearly all of the waters of the creek, at any time of the year, thereby draining the whole of this immense deposit of gravel, and opening a claim at once rich and inexhaustible. Accordingly, last fall he commenced operations by putting in a flume twelve feet wide, divided into two compartments of six feet each. He now has in 400 feet, firmly fastened to the bedrock by ties and other supports, to relieve the force of the water when unusually high. The flume has a grade of one and a half inches, and during the late storm it worked beautifully, thereby demonstrating the fact that with a reasonable amount of water he could run off a large quantity of gravel and dirt that would pay splendid wages for moving, it prospecting much better than even the owner anticipated. He is now preparing to put up a derrick, which, when finished, will greatly facilitate the removal of heavy boulders, of which there are a large number in the next hundred yards; after that the ground becomes less rocky, and he can work to much greater advantage.

Judging from the prospects now obtained, further outlay will be unnecessary, a sit will not only pay for itself as they go ahead, but also pay good dividends. If, however, it pays expenses for building until the heavier banks of gravel are reached, it will, without doubt, be one of the best paying claims in the county, especially as Mr. Jacks has a splendid water privilege—independent of the waters of Spanish creek—which covers the surrounding country.

The owner deserves to have bright prospects, for he has shown indomitable perseverance in overcoming obstacles which dismayed others.

Gaoom Distaict.—From G. J. Gardner, who keeps store at the mines, we learn that the sawmill is nearly completed, and also the hoisting works for the mine. Owing to the scarcity of lumber the completion of these has been prevented for a short time. As soon as it arrives things will be finished up, and a big force of men will be placed to work on the mines and sawmill. M. P. Gossett, a son of one of the English owners of the Groom district property, has recently been on a visit there and expresses himself as pleased with the prospects of the company.—*Pioche Record.*

Sheriff's Sale.—The Huhn & Hunt mine, comprising or embracing the following lodes or leads: Pacific tunnel mining company, 800 feet of Pacific ledge No. 2, 800 feet Pacific tunnel No. 3, 800 feet Pacific tunnel No. 4; 550 feet of the Desdemona east extension; also the easterly 200 feet of the Desdemona mine were sold to satisfy judgments obtained against the Huhu & Hunt mine by M. Cavanaugh and others. The above property was bought by P. Felsenthal, as trustee for the judgment creditors, for the amounts of the judgments, costs and accruing costs.—*Pioche Record.*

The O'Hara Furnace.

At Pearine district, Nevada, great difficulty has been found in working the ore. The Pos Consolidated company have made experiments in several directions with their ore, but have not been successful. They recently struck a fine, well defined ledge in the lower level of the mine, assaying very high. The managers of the Consolidated Pos accepted on the 23d ult. the new O'Hara furnace, being satisfied that it would work their ores successfully to within ninety per cent. of assay value. The *Nevada State Journal* (Reno) gives the following description of how this furnace works the ore of the Consolidated Poe mine, also several important items about this new mode of treating Pearine ore:

The ore of the Consolidated Poe mine is crushed through a ten-stamp dry battery, from whence it is elevated continuously as it discharges from the battery to a large hopper, from which it feeds into the O'Hara Champion chloridizing furnace. The ore is moved by mechanical arrangements through the flames, for the space of two hundred feet, and passes out on the cooling hearth, from which is discharged regularly in the car ready for the amalgamating pans. The furnace is a double furnace of two hearths, and is one hundred and ten feet long, four and a half feet wide, and fourteen feet high. The arches over the roasting hearths are eight inches from the hearths, confining the heat directly to the ore. There is one fire chamber for the upper hearth and two for the lower hearth. The ore is moved by an endless chain with two iron frames, on which are fastened a series of plows, so arranged that one is a little behind the other, so that each following plow turns the ore over into the furrow that the first one has made. The ore is turned to the right and then to the left every two minutes, and every time the plows pass through the ore, it moves a few inches ahead. The ore moves in contact with the flames and is heated up evenly and gradually until it reaches the first fire, when it falls to the lower hearth, where the heat increases, and is then moved back to the end of the furnace through the flames of the two fires, and after passing the last fire it is still moved and turned over a space of fifteen feet on a cooling hearth and is discharged into the car cool and ready for the amalgamating process.

There are no chemicals used in the ore but chlorids of sodium (salt). When the ore gets under a low heat the sulphur commences to burn the lead, antimony, zinc, iron, copper and other base metals, changed to a sulphate, caused by the superheated steam playing through the flames and oxygen from the atmosphere. When the ore falls to the lower hearth the most of the base metals are oxidized, while the silver remains as a sulphate. Now from five to eight per cent. of salt is fed into the ore from a hopper that discharges about a pound every time the plows pass along. The ore being under an increased heat with the oxygen from the atmosphere mixing with the flames, caused by the draft and also superheated steam, causes chemical changes to take place, and thereby changes the silver and gold to a chlorids. The sulphates decompose the sulphur liberated, unite with oxygen and hydrogen, creating sulphuric acid, which attacks the salt, decomposes it and liberates the chlorine gas from the soda silver, having a strong chemical affinity for chlorine, takes up a portion and is converted into a chloride of silver, which is easily amalgamated when brought in contact with mercury in an iron pan. The ore of the Con. Poe, and in fact all the ores in the district, are of a very rebellious nature and have been found very difficult to work, but it is found of late that the O'Hara furnace will work the ore up to 90 per cent. These ores are the most complicated chemical compounds to be found in Nature's laboratory. The ore is from 30 to 90 per cent. metal, with hardly any gangues such as quartz or spar, but in fact is made up of antimony, lead, tin, zinc, cobalt, nickel, iron and copper, with silver and a very little gold and a large per cent. of sulphur and arsenic. The chemical analysis proves it to be argentiferous silver-fahl ore, argentiferous gray copper ore, miargyrite, stromeyerite, zinc blende, iron pyrites, sulphide of antimony, and galena with sulphurets of silver, and silver held in all the other compounds. The ore pays from $20 up to $300 per ton. Argentiferous-fahl ore is a compound of copper, antimony, arsenic, sulphur, lead, iron, zinc and silver, and sometimes gold and quicksilver. Miargyrite is sulphuret of silver and antimony; stromeyerite is a sulphuret of silver and copper; zinc blende is a sulphuret of zinc and silver.

Pump Accommodation.—The New York mining company, Lower Gold Hill, have very kindly loaned the Ophir company their powerful new pump bob, just completed, in order that the Ophir pump may be started at the earliest possible opportunity. The ponderous timber and iron work constituting the bob aforesaid was hauled up to Virginia by heavy teams yesterday afternoon, and will be put into working position at once. The Ophir folks propose having their mine pumped dry inside of two weeks from now. This was a very good and appreciable accommodation on the part of the New York company. Meanwhile, however, their own mine will not suffer by it, as the water is easily kept reduced by the well arranged and capacious bailing tanks. By the time a pump bob is needed the Ophir company will provide one for them or they will do so themselves.—*Gold Hill News.*

The Signal Service.

The report of the Signal Service officer of the army shows that the display of cautionary day and night signals, upon the lakes and at the great ports of the United States, has been made systematically on occasions of supposed especial danger at forty-three different stations. Of the total number of cautionary signals thus displayed, seventy-six per cent. have been afterward reported as justified. In the cases reported as failures the winds did not attain at the place of display a violence held to justify it, while in isolated instances the signals have not been displayed when they ought to have been. The accounts show that no great storm has swept over any considerable number of the posts of the United States without preannouncement. In instances of disaster to vessels occurring during the year, the facts have proved that the watch kept by the service, and the prompt transmission in times of danger of a few messages, have saved property amounting to more than the cost of the lines.

The scanty force of this Signal Service will not permit it to occupy lines greater in extent than those contemplated in existing legislation. Legislation for a more complete organization of the Signal Service is urged as necessary now, both for the interests of the United States and as simple justice to the officers and men who have served so long and so faithfully upon it, with duties now as extensive, as important, and reaching directly more interests of the people of the United States than those of any other bureau of the War Department. It exists without laws providing for the permanent employment and grade of its officers or the promotion of its enlisted men. The service depends for its success upon a rapidity of action, which may save minutes of time. It cannot be too safely guarded against possible hamperings. The Chief Signal officer finds as his reviews the results of the year causes for encouragement.

Copper Mines in Utah.

A correspondent of the Salt Lake *Tribune* writes as follows of the copper mines in the Little Cottonwood canon: All around the head of Grizzly flat are numerous mines of argentiferous copper, mostly in the state of oxides and carbonate ores. Among the most prominent mines may be mentioned the Utah, which shows a vein from four to ten feet wide, carrying from ten to thirty per cent. copper, with from seven to one hundred ounces of silver to the ton. The Lincoln has an immense vein of ore, carrying from fifteen to forty per cent. of copper, with a good quantity of silver. This is one of the largest mines of copper in the district.

The Nellie, owned by McAvoy & Haight, shows a fine lode of copper and silver, carrying some forty per cent. of copper, and from sixty to one hundred ounces of silver to the ton. Above the Nellie comes the Dion mine, showing a vein said to be over forty feet wide, which will average twelve per cent. copper and twenty-two ounces of silver to the ton.

Besides these mines there are many others, among which may be noticed the Darlington, Olive, Morrill, Green Monster, Vanderbilt, Regulator, Mollie G. Corsair, and Box Elder.

The necessity of some mode of reduction at home, is one that will always be felt until it is supplied. With the list of mines I have above enumerated to draw upon, (many of them at present shipping ore), there is certainly no lack of material to work upon, and the number might be largely increased from the prospects already opened. There is no better field for enterprise than here in working of copper ores. With the new wet processes, there is an immense fortune for the inventor.

The Ridge Lead.—It appears to be definitely proven now that an ancient river channel runs along the Town Talk ridge, and extends as far down as Randolph hill, below Grass Valley. The Randolph Hill, the Hope and the Alta companies are supposed to be on the same lead. Recently, Mr. Wellington, Mr. Beatty, Mr. Maltman and others, have struck it out near McKeon's ranch. The contractors who are running the railroad tunnel at the Town Talk hill have also struck the top of the channel, which is forty or fifty feet in width, and Mr. Lord has been working on the same lead near the railroad tunnel for some time. It is thought that the Murchie gravel mines are a part of the same channel, and that the gold found in the gravel on Gold flat came from the channel, by its being cut in two, and washed from the ridge down over the flat. Of course a great deal of the talk is mere conjecture, and may not prove to be correct, but the evidences now are pretty good in substantiation of the theory. So far as known, it is thought the channel is not a wide one, and the gravel, as far as prospected, is not very rich, but the bottom has not been reached, nor any extensive work been done. Enough, however, has been developed to show that a new field awaits the enterprise of prospectors, which may, when fully opened, prove to be very valuable.—*Nevada Transcript.*

Fast Horseback Riding.—At a fair at Waco, Texas, lately, a horseman rode for a wager sixty miles in two hours and fifty-five minutes, using relays of ordinary Texas horses to the number of forty-two. His last mile was made in two minutes and seven seconds, and his time for the sixty miles was five minutes better than the best time ever recorded in this method of racing.

SCIENTIFIC PROGRESS.

Artificial Production of Organic Bodies.

The *Popular Science Monthly* publishes from the pen of Professor Ira Remsen, of Williams college, an interesting article on "The Artificial Preparation of Organic Bodies," from which we collate as follows:

Up to within a few years the belief has been almost universal that the production of organic bodies could be realized only through mysterious influence of life in living organisms—that the skill of the chemist could go no farther than the production of the so called inorganic bodies. This belief grew gradually to be a religious and philosophical dogma which elicited much discussion. But while these discussions were taking place, the chemist quietly continued experimenting with the elements, and discovery followed discovery until the fact could no longer be doubted that the dogma must fall, and fall it did. Its fall, moreover, has given place to a hypothetical statement founded upon a long array of facts, that every chemical body, no matter how complicated or what its nature may be, will in good time be artificially prepared in the chemist's laboratory.

Toward the realization of this statement, a large number of compounds, formerly supposed to be dependent upon the action of the so-called vital force, have already been produced exclusively by the chemist's skill. Prof. Remsen reviews, at considerable length, the steps of progress in this direction, to which we can only briefly refer.

In the year 1828, Wohler made the first success in the production of well developed chrystals of *urea*—a substance well known, but previously found only among the products formed in animal bodies. In 1841, Fownes succeeded in preparing cyanogen directly from its elements. A number of other discoveries followed these—all of which were somewhat simple in character.

But in 1856, Berthelot published a series of brilliant experiments in which the compounds formed were quite numerous, of a more complicated character and of a higher order. From this time on, new methods of investigation were introduced, the growth of the new science became very rapid, and finally the last of the old landmarks between inorganic and organic bodies was swept away and vital force, so far as it was considered essential to the formation of organic bodies, lost its prestige.

Scientists now look upon all substances not in mere mechanical union, as purely chemical, and as bound together by chemical laws, simply and alone; that no difference exists between like bodies, whether formed inside a living organism or in the chemist's laboratory.

Chemists have now at their command many means of building up from their simple elements the most complicated organic bodies. Without reference to their historic order, a few of the later achievements which have delighted and astonished the world may here be briefly noted:

Among the vegetable products are oxalic acid; valeric acid; malic acid, one of the most widely distributed acids of the vegetable kingdom; cinnic acid; wintergreen oil; the oil of garlic; the oil of mustard and the beautiful colors, alizirine and indigo, etc.

Among the animal products that have yielded up the secrets of their structure to the chemist are the simple fats and lactic acids. Leucine is now more readily obtained by artificial means than by extraction from the tissues in which it exists ready formed. Creatine, a constant ingredient of the juice of flesh, and sarcosine, a product of the decomposition of creatine, can now be readily obtained chemically; also, taurine, which occurs in the bile, and in some of the tissues.

These examples suffice to indicate the character of the results already achieved, and furnish justification for the hope now entertained by chemists, that in good time it will be possible to produce all chemical substances in the laboratory. When the active agent in the formation of the so-called organic bodies first became known, the conditions for its working became subjects of earnest inquiry, and an almost endless series of possibilities presented itself. Years ages may elapse before our researches in this direction can be exhaustive. We are ascending a mountain of light. Our views are becoming more and more extended as we reach higher and higher portions. Should we ever be able to reach the summit, there would be found a pleasant harmony in the broad panorama, and our eyes would rest in delight upon it.

The angular velocity of clouds is determined by M. Hursan de Villeneuve in the following way: He takes a ball of silver glass, on which he draws with ink on equator and equidistant meridians. He places the sphere so that, the axis being horizontal, the cloud may be seen, by reflection, displaced along the equator traced, and then the time which it takes to go from one meridian to the next gives the angular velocity.

Cavendish showed that nitrogen and oxygen in air formed a mixture only, but that the passage of electric sparks produced their chemical combination—nitric acid being the result.

A Physiological Problem.

A rather curious problem for physiologists is engendered by experiments recently tried by M. Ponchet upon a puppy. It is the general opinion that the brain of an infant, when the eyes are first used, or that of a person born blind and afterward restored to sight, is unable to translate correctly the impressions conveyed from the retina by the optic nerve. The individual has no idea, it is asserted, of relative distances, nor of the relative physical characteristics of bodies, but only learns the same through practice, and therefore it is to be expected that the sudden restoration of sight will result in a kind of optical confusion, which is only reduced to order after lapse of time. M. Ponchet's experiment, however, seems to negative all this, so far as the use of one eye is concerned; that is to say, if a person, blind in one eye, regains sight therein, and at the same time loses vision in the former perfect organ, the newly acquired sight is exactly as good as that lost, and the new eye requires no education whatever. The eyelids of one eye of a puppy, immediately after birth, were surgically treated so as to cause them to grow together, completely of course shutting off vision from the organ. The animal as it grew used but the single eye until it was four months old, when the good eye was similarly closed and the eyelids of the other opened. Although the left eye had never been used, and although it served as the sole means of sight, not the slightest difference could be detected in the actions of the animal. It recognized objects or avoided obstacles with perfect facility, and, in brief, the most careful examination failed to prove that the dog experienced any different sensations from those to which it had become accustomed.

The subject is interesting in view of the theory which already exists of there being corresponding points in both retinas, from which vibrations are transmitted to the brain.—*Scientific American.*

Power of Gunpowder.—M. De Saint Robert, in an article from his pen in *La Revue Scientifique*, gives the following calculation of the efficiency of a rifled cannon, the diameter of the bore of which is three inches, the shell of which weighs about 8.4 lbs., and the firing charge of which is 1¼ lbs. It may thus be estimated: Experiment has shown that velocity of the shell when it leaves the mouth of the cannon is about 1,300 feet per second. The hight from which the projectile would have to fall to acquire this velocity is 26,800 feet. Consequently the work actually done by the power is equal to 219,000 foot pounds. On the other hand, Bonson and Schischkoff have found by direct experiment that the heat evolved by the combustion of 2.2 lbs. of gunpowder is equal to 618.5 calorics. Hence the heat evolved by the above charge of 1¼ lbs. of powder is equal to 340.7 calorics. The mechanical work corresponding to this amount of heat is 1,050,000 foot pounds. Comparing this, which is the possible mechanical work, with the actual work done on the projectile as given above, the ratio is 0.208 for the effectiveness of the cannon, that is to say, about 21 per cent.

The Andes Gradually Sinking.—A list of altitudes of some of the most important points of the Andes determined at distinct intervals of time, seems to furnish evidence that the mountains are gradually sinking throughout, at least, a large portion of their extent. Quito was found by La Condamine, in 1745, to be 9,596 feet above the sea; Humboldt, in 1803, could only make 9,550 feet of it; Boussingault, in 1831, was startled to find it only 9,567 feet; Orton, in 1867, found it reduced to 9,250 feet, and Reiss and Stubel (doubtless to their honor) found, in 1870, that it had shrunk to the ridiculously small size of only 9,350 feet above the level of the sea. Quito, it seems, has sunk 243 feet in 125 years, and Pichincha 218 feet in the same period. Its crater has sunk 425 feet during the last 26 years, and Antisana 165 feet in 64 years. It is, however, a doubtful point whether this continued depression of the Andes is attributed to the sinking of the mountains or the rising of the world.

Fermentation from Inorganic Substances.—M. Mairet communicates to the French Academy of Sciences a curious experiment which, from the extraordinary result, leads to the belief that either the author has failed to take into account some circumstances not noticed, or else that a discovery of importance, worthy of further and careful investigation, has been made. He says that he mixed acetate of potash, nitrate of potash, and phosphate of soda together, all being in aqueous solution. At the end of a few days, the acetic acid appeared to be destroyed, nitrogen was disengaged, and the liquid contained only carbonate of potash and phosphate of soda. The notion may be compared to a sort of fermentation in the acetate, and more especially since it was accompanied by the development in the liquid of a glassy substance, similar to that which sometimes accompanies the fermentation of sugar.

Action of Heat on Coal.—A *resume* of the experiments of M. Reickert on this subject shows that coal pulverized and heated to between 180° and 200° increases in weight up, to a twenty-hours' exposure to this heat, when it begins to diminish. The specific gravity is also affected by this method of treatment, coals of the specific gravities of 1,328, 1,319 and 1,299 having, after heating, specific gravities of 1,496, 1,495 and 1,471 respectively.

Storms Crossing the Atlantic.—The report for 1873 of the Director of the Meteorological Observatory in Central Park—which has just made its appearance—besides containing monthly tables of the condition of the barometer and thermometer, the depth of rainfall and the velocity of the wind, considers this interesting question: Do any American storms cross the Atlantic to Europe? Director Draper compares observations and records of storms occurring on this side of the ocean with the logs of western bound steamships, answers the question in the affirmative, and says that "the places where ships may meet them [the storms] at sea and the time of their [the storms'] arrival in Europe, may be predicted within certain limits." How warning can be conveyed to the ships raises another and more difficult question.—*New York Evening Post.*

MECHANICAL PROGRESS.

Injurious Effects of Snow on Steel Rails.

Some interesting observations under this head are communicated from an Austrian line of railway, the Kaiser Ferdinand northern line. A portion of this line, about eight English miles in length, is very open, and often blocked with snow in winter. The obstacle is generally surmounted by strewing sand over the rails in front of the driving wheels. This portion of the line in question has a double line of rails, partly of Bessemer steel rails and partly of light Martin steel rails. Now, the skidding of the wheels frequently caused heating of the tires and rails, which are suddenly cooled again by the low temperature of the air on the falling snow. This, in itself, must be injurious to the molecular construction of the metal. But, beside, the increased friction causes a certain amount of abrasion of the upper surface of the rails at the spots where the stoppages have occurred. Examinations proved that these abraded portions varied in length from two to nine English inches in length, one-twelfth to one-fourth inch in depth, and extended over the whole breadth of the rail. A train in passing over the depressions so caused necessarily experiences a certain shock, and it is reasonable to suppose that the concussion thereby communicated to the rail will be most felt when the ground beneath is frozen hard, so that natural elasticity of the rails has no room to play. In three instances rails so worn snapped asunder suddenly at the abraded portion, although no flaw or defect in the metal could be detected. This led to the removal of all abraded rails from this section of the line, amounting to twenty-eight lengths of Martin steel rails, and ten lengths of Bessemer rails. No similar case of fracture is known to have occurred in the iron or puddled steel rails previously in use, although the amount of abrasion they underwent must have been at least as great. The inference is that the improved rails of Bessemer and other steels, their superior strength notwithstanding, are less capable of withstanding concussion than the older (iron) rails, and consequently whenever they are used increased vigilance is requisite to prevent accidents in the winter time.—*Zeitschrift.*

The Brayton Oil Engine.

The Brayton gas engine, a motor driven by the combustion of ordinary street gas mingled with air, and now quite well known to engineers, has been made the basis of another invention of somewhat similar nature, in which the motive power is furnished by burning a mixture of crude petroleum vapor and air. The oil engine, as far as we have been able to learn, and judging from our own brief inspection of its workings, bids fair to be a successful machine, and one of considerable utility to those who require light power, but who wish to avoid the inconvenience of steam. The engine which we saw in operation was alleged to be of five-horse power, and served to run a variety of metal-working machine tools.

The expense of its working, we were told, was only the cost of five gallons of crude petroleum per day, averaging some forty cents. A small pump lifts the petroleum directly from the barrel to the cylinder. An air pump compresses air into a reservoir at the lower part of the machine. The air current passes to the cylinder, and in suitable proportion mingles with the oil, which is introduced in the form of spray. The mixture, by a small flame which is constantly maintained, becomes ignited, expands, and so acts upon the pisten.

We clip the above from the *Scientific American*, which journal appears to attach considerable importance to the invention, and promises, at a future day, to give a more minute description of the apparatus.

Curious Electrical Phenomena.—A piece of wood cut from a tree is a good conductor; let it be heated and dried, it becomes an insulator; let it be baked to charcoal, it becomes a good conductor again; burn it to ashes, and it becomes an insulator once more. The coarse long hair from the neck of an old ohamois, if drawn between the fingers and thumb from the root to the point, becomes positively electrified, but if drawn in the reverse direction it becomes negatively electrified.

The strain on belts is always in the direction of their length; and therefore holes cut for the reception of lacings should be oval, the long diameter being in line with the belt.

Belting vs. Frictional Gearing.

In the early part of 1872, says the *Scientific American*, we published a series of carefully prepared papers on frictional gearing, giving results of experiments therewith, made to determine the percentage of adhesive force or traction of these wheels as compared with belted pulleys. From these tests it appears that the traction of the friction wheels was greater than that of the belted pulleys, and considerably more than is usually supposed to be obtained from belts upon pulleys of either wood or iron; and that, while there is a marked falling off in the adhesion of the belt as the work increases, that of the friction gear increases as the labor becomes greater.

We have lately received a letter from Messrs. Brownlee & Co., of Havelock, Marlborough, New Zealand, which details results considerably at variance with those above noted. Our correspondents say: "We had prepared plans for a saw mill, to be driven by friction instead of by belting; but before ordering machinery, we came to the conclusion we had better make a trial on the same principles as set forth in the *Scientific American*," (alluding to the records of the tests given in the series of articles above referred to,) "and obtained the following results, which rather staggered us: Instead of a 6 inch belt, we used a 3¼ inch on 17 inch pulleys. The belt without slip showed that 136 pounds raised 70 pounds; 320 pounds raised 153 pounds. Friction gearing without slip, 136 pounds raised 57 pounds; 190 pounds raised 54 pounds; and 320 pounds raised 84 pounds."

These last results, though not wholly in accordance with those given by the writer who communicated the articles, are reasonably near; but those given by the belting certainly are wholly out of proportion. Messrs. Brownlee & Co. say that they tried the friction gearing with one-half the face, namely 1¾ inches, and obtained the same result, that is, the same weight was raised.

This is an interesting question of practice, and probably some of our practical readers can throw some light on the wide discrepancy noted. We should very much like to hear, from mechanics who have tested the relative efficiency of belt pulley and friction gear, their views on the subject.

The T rail exhibits a disposition to change its form. It is now being rolled with a wider flange or base and a thicker head, without increasing the standard weight of sixty-seven pounds to a yard. The material of the upright part is reduced to make up for the increased size of the base and head. The head is made more nearly square at the sides, and the edges of the base are thinner. The object of this is to increase the resistance to wearing by the flanges of the wheels, and to prevent the rail from cutting into the sleepers. In place of the notches cut in the rail to hold the spikes that have been found so destructive to the life of the rail, holes are now drilled through the base, and through these the rail is fastened to the road bed.—*Scribner.*

Patterns for Scroll Work.—A ready way of making patterns for scroll saw work is given as follows: "Take the bracket or other piece of work which you desire to copy, and spread it over a sheet of paper, securing it from slipping. Rub gently over it a piece of saddler's black leather. All the outlines will be marked accurately, and it takes but a minute to copy any piece. The saving in money for patterns, which cost from ten to twenty cents in the stores, is therefore considerable, and it is often impossible to get a pattern of some particular thing which strikes your fancy."

The Bastie Glass.—A large building for the manufacture of malleable glass by the Bastie process has been commenced in France, at a cost of $625,000. The building is 163 yards by 160 yards in depth. It has been assured that utensils, such as fry pans, etc., can be used on a hot range, and will resist the fire just as well as iron or any other metal. Also, glass chimneys for lamps and gas burners are made, and will not break. In fact, there is no limit to the variety of articles which can be made of malleable glass.

Steel Ships.—The British admiralty having decided upon the construction of two dispatch vessels to be made entirely of steel, the order for the plates and bars for the same has been given to the Landore Siemens steel company, of Swansea, who undertake to supply a very mild steel of high quality.

Truing Oilstones.—For truing an ordinary oilstone for sharpening planes, take a sheet of glass paper No. 2, and place it on the bench. Rub the stone over it. In this way the stone can be trued in one-quarter the time required by the ordinary process.

The truest threads in holes are cut from taps having no clearance in the threads. Such taps also cut threads more uniform in size than those having clearance in the thread.

The corners of the square head of a tap should be well rounded or chamfered off, so that the wrench will readily adjust itself to the square of the top.

Brass wire should be softened before being used for rivets. To soften, heat and allow to cool or dip in water.

The Mining Share Market.

Stocks have been "off" during the past week, prices having shaded down considerably since our last report. The hopes entsrtained of a hig rise was fallacions, for after the recent spurt a falling off has manifssted itself. Some of the dealsrs now think the rise will come after the holidays, aud others pnt it off to "sprinq." Thsre have besn no spscial features in any of ths Bosrds recently worthy of record; the market having been particularly dnll. Ophir, instead of heing at $70, as many hopsd, hss struck ahont $50, whioh is an indication of how ths markst stands.

The Comstock still oomes nohly to the front. Consolidsted Virginia announces its nsual monthly dividend of $1,080,000, notwithstanding ths total dsstrnotion of the hoisting works ol' the miue and the very limited facilities for ore extraction through the Gould & Curry shaft since then. This shows a good mine, good manqement snd finamical ahility, hacked hy a very healthy trsasury. At this mins about 100 tons of ore psr day is heing hoisted through the Gonld & Curry shaft, aud crnshed as fast as taken ont, which will muoh more than pay the running sxpeuses of the mins. Hoisting from the new works has already hegun.

The new works of the Ophir have also bssn startsd up. Thsse works were completsd in the nnprecedently short tims of thirty days. This reflecls grsat credit upon Snpsxintsndeut Cnr-tis and his assistsnts. The Belcher has done well this month too, and ths stock raised a little in consequencs. This old dividsnd paysr may come hack to the ranks soon if it kesps on. The Bslcher and Crown Point companies have sntsred into an agreemsnt whereby the new air shaft is to he sunk jointly hy the two mines and it is to he made a drain as well as an air shaft. Plans and specifications have heen adopted for a large compound condensing engiue and pumping machinery, which is to he procured aud erected in the shortest possible time.

At the California mine the amalgamation mill started up last week on tailinge and pulp saved from the Consolidated Virginia mill hefore it wae hurned. The huilding over the works of the new hsttery mill are finiehed, and the erection of the hatteries and machinery is progressing at a very favorahle rate. Some delays are being experienced in obtaining the right kinds of timber, and in getting the mortars for tbe hatteries from the fonndries. These mattsrs, however, will soon he overcome and everything again in readiness to commence oruehing ore.

MINING STOCKHOLDERS' DIRECTORY.

MINING SUMMARY.

THE following is mostly condensed from Journale published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

RICH ROCK.—Amador *Ledger*, Dec. 4: We are informsd that at Pine's mine, at West Point bridge, thsre are some 160 tons of rock on the dump, whioh will avsrage $40 to the ton. The work of crushing is heiug pushed forward. Some six or sight men are employed on the claim.

GRIZZLY HILL GRAVEL MINE.—James Hsll & Co., ths owners of thie claim, which is situatsd at Volcano, have just completed the laying of 3,000 ft of pipe, and are now engaged in oleauing out the ditoh, preparatory to the commencemsnt of miniug operations. The mine will he in full hlast in a few days.

ALPINE.

EXCHEQUER.—Alpine *Chronicle*, Nov. 27:—A large number of the men of this miue have heen at work on the company's road this week.

ADVANCE.—Most of thie week has heen spent in huilding an engine house.

BUTTE.

MINING. — Oroville *Mercury*, Dec. 3: It is only occasionally that we see a miner in town now-a-days, and then only for a minute at a time, as he runs from store to etore. The raine that have fallen, very moderately so far, have sosked the gronnd now so that it is full of weter. The ditches are all full and the contiuuous raine keep them so. On every mining claim the men, enveloped in rnbher hats, coats, pante and hoots, can he seen fnnrrying here and there, turning the different stresms so as to make the best possible nse of them. More than nsual preparations have heen made in all the claims for carrying on the hnsiness thie winter, and we shall he greatly surprised if a greater golden harvest is not gathered than duriug any previons year. Every prospect points that way now.

ELEOTRIO MINE.—We hear thst a body of excellent ore has hsen struck in the Electric mine. As the rains have hesn sufficisut to furnish all the water needed to crush the rock, we shall expeot to hsar a good acconnt of it soon.

AT WORK.—The Bidwell hsr clsim, owued by A. J. Severance, is hsing put iu a condition for working. In s few days the chiefs will get into positiou to storm the auriferous hanks. C. M. Ury superintends the work, and as he is an experisuced miner the prospect is flattering for a good harvsst.

INYO.

MILL FOR LEE DISTRICT.—Inyo *Independent*, Dec. 4: This district, ahout which hut little is generslly known, lies some fifteen miles north of Darwin, toward Csrro Gordo. It is said a mine there of great promise has heen so far developed as to justify the erection of a mill, and that Mr. Lynch, one of the owusrs, has the machinery now on the wsy to put one np.

IMPORTANT IF TRUE.—It is reported, and we are disposed to helisve the report true, that a settlemsut of ths Ssn Fslipe Union mining suit has heen effected, and that iu consequence prospsrons timss will again smile on Cs

the Kearsarge company, arrived here this week. He comes with the view of inaugurating active work on the mine at once, or immediately after the arrival from San Francisco of another member of the company, expected daily. The plan is to keep a small force at work taking out ore during the winter, and to start the mill and put on a full crew as soon as practicable in the spring. Since Mr. Gray's last visit here he has devoted time and money to systematic tests of the Kearsarge ores, to determine what process holds out the best inducements. We are not able to state the final conclusion on the point further than to say that it is found that the ordinary process, such as has been adopted in the Kearsarge mill heretofore, will give no more than 35 per cent. from the rich ores taken from the deeper workings, say below 200 ft.

Coso District.—Coso *Mining News*, Dec. 4: The developments in our mines during the past week have been of most satisfactory character and our superintendents all wear smiling countenances, for every stroke of the pick reveals new treasures and gives additional cause for congratulation. Our review is principally confined to those mines that are being prospected extensively, the results from which are being watched with deep interest by all. The principal mines are open for inspection to all desiring accurate knowledge of their condition and are daily visited by residents and strangers who come away with enthusiastic praises over their magnificent appearances. The Defiance furnace is at last completed, and after a few preliminary tests will be kept constantly running.

KERN.

The Somner Mine.—Kern County *Courier*, Dec. 4: Senator Jones is expected at Kernville next week, on a flying visit to his mine before his departure for Washington. Although not making as much noise as other places, the Sumner mine is probably the best piece of property the Senator has. Under the efficient management of Burke, although it is very low grade ore on the average, it is one of the best paying mines in the State—$75,000 to $100,000 per month, we are informed, being its net profit to the owners. All the conditions of this mine seem to be of the most fortunate. The lead is very wide, the rock of uniform richness, all the rock extracted paying. The mill is run by water, of which there is an abundant and never failing supply, and the new eighty stamp mill is furnished with all the latest and most approved appliances for economizing time and labor and saving the precious metal. The management is now engaged in sinking to a still greater depth, and at the point reached last week the workmen had struck a body of rock that gives seventy-five dollars in gold to the ton. This is very much higher than the usual grade of ores, and as they still descend they have every reason to expect to strike a veritable bonanza.

NAPA.

Magnificent Specimens.—St. Helena *Star*, Dec. 2: We are in receipt of some beautiful specimens of cinnabar and black oxide of mercury from the Phœnix mine, Pope valley. They are handed us by a gentleman just over from that mine, and he says things look well, and are in good shape. The new furnace, with its double fire-place, does splendid work, with half the amount of fuel formerly used by the old one. We would suggest to the superintendent that if he has many such specimens left he should send some of the finest to the Centennial exhibition. We should give Napa county as high a place as possible in the forthcoming exhibition, as the other portions of the State are striving to be represented in all ways and shapes as regards both agricultural and mining resources.

NEVADA.

Our Mines.—*Foothill Tidings*, Dec. 4: Our quartz mines continue to send out bullion at about the same rate as before the rains set in. Idaho, Empire, Omaha, New York Hill and others of our producing mines keep right on as if no rainy season was here.

The fire-proof building to cover the new hoisting works at the Idaho mine, was on the verge of completion when the heavy rains set in. Not much show to work at it since, but a few days of fair weather will see it through.

PLACER.

The Krueger.—Placer *Argus*, Dec. 4: The Kidder claim at Iowa hill has been running for some time with encouraging prospects.

The Bay State and North Star claims at Gold Run are in full blast, washing out the gravel.

There is a pile of hydraulic pipe at the station. It belongs on the Michigan Bluff divide.

Griffith's granite works at Penryn are turning out some splendid monuments.

More hydraulic claims will be worked in Placer county this season than ever before.

The jury in the Iowa Hill canal case returned a verdict for the company.

The Auburn gravel mine is running again.

The St. Patrick mine is looking better than ever.

Two little giants have been received at the depot; one for T. Harper, at Todd's valley, and the other for Ryan & Middleton, Michigan Bluff.

Iowa Hill is looking up. Its future prospects are bright with promise, and before long it will be the best mining town in the county. The Iowa Hill canal did it.

Dutch Flat Mines.—Placer *Herald*, Dec. 4: The Yankee claim is, we believe, the largest in the district. It employs 25 men on the day shift and about half that number on the night shift. This company is now running a tunnel from Bear river to tap the bottom of their immense gravel deposit. The tunnel is now in 1100 ft, about one-third of its proposed length. They have been washing for some time, but owing to a break in one of their pipes, a detention of a day or so was caused. Another walk of about one mile across a section of country, the surface of which had been washed off, and we arrived at the North Star claim. This claim commenced washing a few days ago, but after a short run, cleaned up, and were putting in new riffles in their sluices through their tunnel. The usual run in all the mines before cleaning up is from 25 to 30 days. We then visited other mines in the immediate vicinity, on which work was apparently being pushed ahead rapidly. The Jehosaphat, Central and Pacific have all commenced washing since the rain, and are running day and night shifts. The Badger shaft, Boston, Franklin, Dutch Flat and Buckeye tunnels are all being driven with vigor. Some few claims in this district have not commenced washing yet, owing to not being in readiness for such an early rain. Altogether the mining interests of this section are being permanently developed, and the prospects for its future prosperity are indeed flattering.

PLUMAS.

Crescent.—Plumas *National*, Dec. 4: The company now owning and working the Crescent mine are getting fairly at it, and under the management of the superintendent, Mr. Pardy, everything goes along smoothly, and the investment promises to be a good one. When work started up, some time ago, the mine and mill had to be thoroughly reconstructed and set to rights. About $7,000 has been the outlay, and the mine has already yielded over $4,000, and is improving steadily. The rock crushed, so far, averages $7.75 per ton, and it would be easy to pick rock that would pay big figures A shaft is now being sunk from the 2d to the 3d level of the mine. We congratulate the managers on the good results obtained, and hope the old Crescent will continue to "ante."

SAN BENITO.

The Quicksilver Mines.—Hollister *Enterprise*, Dec. 4: The late heavy rains have retarded work to some extent in the quicksilver mines of the Coast range, yet several hands have been at work all along in the Consolidated Wonder claims. Two tunnels are being driven; one is in 100 ft, and the other 50 ft. Mr. Shackelford, who returned from the mines Wednesday, thinks they will strike a heavy body of metal in both tunnels, in the next 100 ft. A new ledge of the richest ore yet (much of it assaying 25 per cent.) has been opened in the last few days, in the vicinity of the Consolidated Wonder mill site. It is said to look very promising; in fact, developments go to prove that these mines will turn out even better than was first anticipated. A large and very rich body of ore has also been recently struck in one of the Stayton mines, near the furnace. Bob is running a tunnel on the new discovery, night and day, and expects to open up, within a few days, an ocean of cinnabar. There is now no question about the wealth of these mines.

SAN DIEGO.

Julian District.—San Diego *Union*, Dec. 2: The Helvetia mining company have bought the Willow Glen company's ten stamp mill. The negotiation for this purchase has been pending for several days, and the sale was completed yesterday. The Helvetia company have taken possession and have started the teams to hauling ore to their new mill, which will be kept running continuously. We may expect to hear from them quite often in the future.

Clean-Up.—San Diego *World*, Nov. 27: From Mr. Hamilton we learn that the Chaparal mine of Julian cleaned up thirty tons of rock a few days since that netted a little over $2,000. The Ella is at work and taking out some good rock. He also reports the country between here and Julian as beginning to put on its holiday attire of green.

STANISLAUS.

Quicksilver.—Stanislaus *News*, Dec. 3: Covert & Co., on the Waterford claim, have repaired their retort and are again smelting out quicksilver. The Orestimba company is also getting out a pretty fair grade of ore. Other companies are likewise at work. Grayson, the headquarters of the quicksilver miners of the county, still talks bonanza language.

SONOMA.

Local Mining Items.—*Russian River Flag*, Nov. 27: Hedge Reynolds, now residing with his family at Pine Flat, was in town the fore part of the week. From him we obtain the following news items: Being appointed special constable by Justice Williams, he has just sold all the attachable property of the Anna Belcher mine. The Blue Jacket has shut down, but will resume in about three months. The American is running with a force of 20 to 30 men. The Wall Street is working a force of 70 or 80 men. The Oakland force is about 40 men. Their carpenters having come down to the Flat it is supposed that the new furnace is completed, and that they will soon be extracting mercury from the immense body of ore they have accumulated on the dump. The Denver company have proposed to the Hope that if they will consolidate and issue with them entirely new stock they will return to them one-third of all expenses they have been to in working the mine thus far. It is supposed that the Chicago will also be incorporated in the proposed new company.

TRINITY.

Damage by the Storm.—Trinity *Journal*, Dec. 4: The warm and heavy rain of Sunday, Monday and Tuesday necessarily raised all the streams in this section, the freshet being greater than since the flood of 1861-62. The big flume in Weaver creek stood the raise remarkably well, and has now been thoroughly tested. About twenty-five boxes at the head were entirely covered and filled with tailings, brush, logs, slabs, and other debris from the dams in the creek above, but the lower end of the flume and the race below worked admirably well. The covering of the upper end of the flume, we are told, has not damaged it to any extent, and under the judicious management of Superintendent Davidson, it will be in running order the whole length, in three or four days.

The Weaverville ditch and hydraulic mining company suffers somewhat by a slide on the line of ditch above the tunnel on West Weaver. The break is now being repaired, fifteen boxes of flume being put in across the gap. The principal loss to the company will be the loss of water during the time necessary to make the repairs, but the superintendent promises that the work shall not be kept back a moment longer than is absolutely required to put the ditch in running order again.

Owing to some accident, the nature of which we did not learn, Mr. Woodbury had the blocks torn from about forty boxes of his Garden Gulch flume. Ten days will be required to repair the damage and put everything in running order once more.

TUOLUMNE.

Cuispas.—*Union Democrat*, Dec. 4: A number of parties residing in Sonora have in the course of their wanderings around town found small chispas and gold bearing quartz varying in value from $2.50 to $20, the late rains having washed the miniature nuggets from their hiding places.

Mill Running.—The mill on the New Albany mine commenced running last week. The indications in the mine itself are good.

Nevada.

WASHOE DISTRICT.

Crown Point.—Gold Hill *News*, Dec. 2: Daily yield, 425 tons of ore. The ore stopes are looking well and continue to afford a supply of ore sufficient to keep the mills steadily running up to their full working capacity. A winze is being sunk below the 1500-ft level, which is now down 55 ft, the bottom in ore of a fair quality. A drift south on the 1600-ft level is being run to reach a point under this winze where an upraise will be started to meet it for ventilation purposes.

Lady Washington.—The bottom of the shaft is in somewhat better sinking ground. No increase of water, and what does come in is handled by the pump with perfect ease. The monster engine, duplicate of the one at the C. & C. shaft, Virginia, operates with the regularity of clockwork, smoothly and almost without noise. No finer piece of machinery is in existence.

Julia.—The bob-pit and pump station at the 1600-ft level is finished, and sinking the shaft resumed. The main southwest drift, on the 1400-ft level, is steadily advancing, the face in quartz and porphyry, with a considerable seepage of water coming in.

Yellow Jacket.—The south drift from the north winze on the 1940-ft level is in a distance of 111 ft, the face of both drifts being dry, good running ground, very favorable for making rapid progress. This leaves about 200 ft for the two drifts yet to run to connect with each other. No material change to report of the cross-cuts on the 1740-ft level.

Sullivan.—Tunnel is 230 feet to-day, and only about 36 feet further to go in order to connect with the shaft. The last 180 feet has been entirely in the very promising vein matter heretofore mentioned, and the shaft, having developed 32 feet of the same, shows it to be about 200 feet in width between the walls, both of which are well defined. This is no doubt a true fissure, and when a proper depth is attained good pay ore and plenty of it will be found. Some streaks and bunches of ore have been met with the past week, assaying as high as $40 to the ton. Grading at the surface for the hoisting works goes ahead energetically.

Lady Bryan.—The shaft is down 550 feet, at which point the sinking has been stopped for a few days, pending the putting in of a pump and box at the 500-ft station. As soon as the pump is finished, sinking the shaft will be resumed. Driving the cross-cut from the main south drift on the 170-ft level is making good headway. It is now in 25 feet. The winze below the 250-ft level is being driven downward at the rate of three feet per day.

New York Consolidated.—The cross-cut at the 800-ft level is progressing finely, and the fine vein of ore, mentioned a day or two since in this paper, as having been found at that point, is opening out very encouragingly, showing promise of a valuable development. Water gives no trouble, there not being much, and what there is the machinery handles without difficulty.

Sierra Nevada.—The main west drift on the 1000-ft level is rapidly advancing, the face in more favorably looking ledge material.

Leo.—Prospecting goes on vigorously, as usual. Face of main drift, from bottom of winze, still in very promising ledge material. Cross-cut from main drift shows more quartz and better indications now than at any time heretofore since it was commenced.

Chollar-Potosi.—Daily yield, 60 tons of ore, the assay value of which is $28 per ton. No change in the appearance of the ore breasts.

Amazon and Glasgow.—Both the north and the south drifts on the 350-ft level show an improvement, and particularly the north drift, the ledge widening and improving in appearance daily.

Buckeye.—The damage to the pump-rod is repaired, and the sinking is going forward as usual. It is now down 60 ft below the 350-ft station.

Florida. — Some very rich streaks and bunches of ore have been passed through during the week, and the prospects of running into a very desirable bonanza are very flattering.

Justice.—The ore at the 600-ft level shows still further improvements in both quality and quantity, and at the 800-ft level the main ore body is evidently reached by the south drift, assays of from $150 to $200 being obtained. The present prospects of the mine are very flattering

Original Gold Hill. — Extraction of ore from the south ore body continues at the rate of about 25 tons per day, which is accumulating in the dump, and hauling it to the mill will commence shortly, a contract being let for that purpose. A new blower, to supply the north drift, starts into operation to-day, and good ore developments are looked for in that direction very shortly.

Nevada.—A drift north is being run from the cross-cut, in the center of the main ledge. This drift is in fine looking vein matter with streaks and bunches of low grade ore.

Leviathan.—Face of main north drift at the 450-ft level in ore of rather poorer quality than heretofore, yet the vein is strong and promising, and the ore already developed at this level is of considerable value, even if no more is discovered without striking deeper.

Globe Consolidated.—The northeast drift on the 350-ft level is steadily advancing, following the west wall of the ledge, the face in quartz of a fine character, carrying spots and bunches of excellent ore.

Bullion.—Sinking the main incline is making excellent progress. The face of the main north drift on the 1700-ft level is still in quartz and ore of a very encouraging character. The new combination drift on the 2000-ft level is also going ahead finely.

Europa.—The main west drift on the 320-ft level is in a distance of 240 feet, the face in very favorable working ledge material.

Woonville Consolidated —The control of this mine has passed into the hands of the owners of the Justice mine. All work has been suspended for the present, the workmen discharged and the mine virtually shut down for the present.

Hale & Norcross.—Over 100 ft of the main shaft have been retimbered and enlarged. Every effort is being used to complete the repairs at as early a moment as possible, as no work can be done in the mine until that is finished.

Imperial-Empire —Daily yield, 40 tons of ore. The ore breasts are looking well, and show an improvement going southward on the 1900-ft level.

Baltimore and American Flat.—Sinking the main incline is making better progress than for some time past, the rock in the bottom blasting out well, there being no water whatever to interfere.

Dayton.—The new pump at the 500-ft station is nearly in, ready to resume sinking.

Gould & Curry,—Everything is in good working condition, and the water is being extracted from the 1700-ft level, preparatory to resuming work in that portion of the mine.

Silver Hill.—The chutes for dumping ore and waste rock at the head of the main incline are nearly finished. Timbering the main incline is making good progress.

Best and Belcher.—Nothing doing below the 1500-ft level, owing to delays of the Gould & Curry pumping machinery in keeping down the flow of water.

North Carson.—Prospecting and ore development at both the upper and lower levels progressing at a lively rate.

The Richmond.—The Eureka *Sentinel* is informed that the Richmond mine has never presented so favorable an appearance as at present. At the 600-ft level fine bodies of ore have been struck, all of which are making downward, and everything indicates that they are on the croppings of a bonanza, which extends indefinitely in the direction of the center of gravitation. As that depth in the Richmond is at least one hundred feet lower than the deepest workings of any other mine on Ruby hill, the recent discoveries are encouraging evidence of the permanency of the deposits in that vicinity.

The machinery of the Meadow Valley mine, instead of being shipped on December 1st from this city, will not be sent to the mine until spring. The mine will be worked as usual, as it is paying its own expenses.

The Belcher and Crown Point mining companies have agreed to join forces in the further sinking of the big air shaft. It will be used both as an air and pumping shaft.

The St. Patrick mine, (Placer county,) shipped on the 5th inst., $13,216 as the product of nineteen days run. The next clean-up will be on January 2d.

Nicholas Coates, a miner employed at the Williams mine, on Prospect mountain, was killed on Wednesday morning by a cave in that mine.

The Petaluma *Argus* says there is some talk of forming a Stock Board in that city to supply a much needed want.

Improvements in Central Nevada.

From a letter of a correspondent of the *Bulletin* on "the Mining Interests of Central Nevada," we make the following extracts:

In jonrneying through the varions mineral districts of Western and Central Nevada, one at all acqueinted with their previous history gets the impression that great advsnces have here been made of late in the business of mining for the precious metals. Nor bave these advances been confined to any single department of this industry. They are general, and go to every province and aspect of it. The very *morale* nf the business has been elevated. A better oode of ethics begins to obtain in these mining communities. The distinction between the fellows who forcibly seize the treasure of the express company and those engaged in vending hogns properties or in promoting frandulent mining schemes is not now so broad as it once was, and the growth of this sentiment calls for gratulation no less than the material progress that has heen made. It should be remarked thet these improvements so universal and noteble have not resulted from the introduction of any new process or invention tending to greatly relieve the husiness from the burdens that most oppress it, uor the occurrence of sny other single event working to that end, bnt simply express the aggregate miner gains achieved during the period mentioned. It is true, many important mineral discoveries have meantime heen made and the mines are generally looking well, while of inventions, some of them really valuable, there has been no lack, yet the advances alluded to have been mainly dne to causes loss controlling and more generally diffused.

Fifteen years have now elapsed since the discovery of silver-bearing deposits on this side the Sierra Nevada drew hither a considerable population from California. The majority of this popnlstion, which was largely made up of men accustomed to deprivation and toil, once nver the monntains have since remained here engaged in searching after, locating snd working the metalliferous lodges that here so abound. Ignorant of the very alphabet of the bnsiness they had everything to learn, snd they had to learn it in one of the roughest schools in which any set of tyros ever received their trsining. But they hsve learned it well—so well that can do their work better, under the circumstances, than could any other cless of men hnwever learned or practically skilled in their vocation as elsewhere pursued. It must be admitted thet these off-hand miners made meny mistskes at first. But not more perhaps than would have been made by any other set of men, the most of them being unavoidable. Latterly these mistakes have not, in the field of practical mining, been serious or many—scarcely more thsn are incident to most other active pursuits.

New Mining Appliances.

Prsoticing his calling under so msny difficulties, the miner here has become observant, inventive and self-reliant. Marvelous are the mske-shifts wherewith he contrives to get on in the absence of those ready made utensils and helps always at hand in older communities. With the imperfect implements he improvises from the soanty material within reach a tolera ble substitute for these unless, to be sure, he mansges to dispense with them altogether. His resources are exhaustless; no man is so rich in expedients or so dextrous in their application as your mountain schooled miner. He extricates himself from a tight place with a facility astounding to the novice. The devices suggested by his ingenuity or bred of his necessities are strange, manifold and almost always simple and efficient. The fruitfulness and versatility of his genius are shown in all his works—in the shop, the mine, the mill and the furnace—everywhere may be detected some original labor or money esving contrivsnce, with endless economies effected in the mechanism, manipulations a nd metallurgy of the gold and silver gathering art. Wood and stone are made to perform the duties of iron, and when steam is beyond bis resch recourse is had to man or mule power. Where he cannot get English fire brick to line his furnaces, he prowls about and somewhere in the neighborhood finds a stone or clay that answers as well, or perhaps better; snd so, while supplying a present, provides agsinst a costly and constsntly recurring want. If mineral coal is not to be hsd he uses charcoal, and when wood fails him altogether, sage brush is made to answer for fuel. He is a subject for wonderment, this Nevada miner, with the disciples of Freiberg and Swansea, who are not more amazed at hie audacity than soandalized through hie shameful departure from the rules of science. But there is no controverting the fact that he opene the mines, gets out the ore and very often extracts the metels as cheaply and well as those men who have enjoyed the benefits of professional instruction and the opportunities of the schoole. It must not be inferred from what hae been said that the miners here neglect to read and study the various worke treating upon subjects connected with their calling. The most of them are well supplied with these and are tolerable conversant with their contents; yet, ae a oless, they seem lese disposed to be governed by the formulas laid down in the hooks, than by a knowledge acquired in practice.

Superior Work—More Bullion and More Profits.

As a general thing the work now being done is much more systematic and thorough than formerly, while the mills and other structures pnt up are so superior to those erected only a few years ago that the latter beside them seem mean and poor. Nor does this snperiority consist in mere adornment and show (of which there was sometimes too much in the esrly dsys), but in the greater excellence of the machinery and the outfitting generally. Everything is now provided with an eye to utility snd service rather than outwsrd display. Already these all prevading improvements are beginning to tell on the gross product of the Nevada mines, though it will yet be some little time before their full effect will be felt on the resultant net profits, inasmuch as heavy expenditnres have sometimes been incurred in the construction of new machinery, the elaboration of improved processes and the promotion of various much needed reforms. Vast sums have been disbursed in the exploration of the mines and in other preliminary labors yielding no immediate return, but from which ample benefits will in due time inure. Latterly but few investments have been made here resulting in loss or that can be considered oommeroisily perilous. Some, at one time regarded as hopeless, promise now to prove remunerative and may even bring large gain to the investors. Viewed as a whole, the mining outlook for Nevada is certainly much better than ever before. The bullion prodnct of the State, which last year amounted to thirty-five and a half millions, will this year exceed forty, with a generally increased percentage of net earnings. * * * * * * *

Railroad Building.

The final completion of the narow-gauge railroad from Palissde to Eureka will grestly advantage both the mining interest and the town itself. The heneficial effects of oheapened and qnickened transportation are already being felt, not only in the vicinage of that place, but even as far south as here; and the extension of this road to Tyho cannot long be delayed, ths necessity therefor being now nesrly as stringent as that which existed for ite construction to Eureka at the time it was commenced. The distance between its present southern terminus and this csmp is only ninety miles. The intervening, and, indeed, the whole country clean on to the Colorado river, cousisting of a smooth, open plain, offering much fewer obstacles to railroad construction than would be encountered along any of the great interior valleys of California. Having once surmounted a low divide in the immediate neighborhood of Eureka, there would be no more elevation to overcome, nor would any embanking, deep cutting or bridging of consequence be required along the entire route, covering a distance of nearly 300 miles. The mountains on either side of this great plain are full of mineral wealth, the mining districts of Spring valley, Secret canon, Morey, Hot creek, Tyho and Reveille having already heen organized in the several ranges that skirt it on the west, with Grant, Troy, Tem-Piute and Groom in those lying to the east. But with all their wealth population is sparse and improvemont is backward here, but little having been done except in Tybe, Reville and one or two other districts, fortunate enough to have obtained aid from abroed.

Should the English company here carry out the comprehensive plans now entertsined by them, their businesa alone would almost justify the bringing on of the road to this point. Having lately purchased a eet of mines lying near and really more valuable than those first owned by them, they purpose now the erection of additional furnaces, and such an extension of their entire operations as must insure the production of immense quantities of crnde bullion, and call for the importation of heavy supplies. Their patrouage alone would go far toward giving a fair support to a road built and run as cheaply as this might he. Bnt theirs would not constitute a tithe of the transportation required to be done were the road laid down this far.

The region covering several parallel rangee of mountains, lying on either side of the great central plain mentioned, and the whole country south to Arizona, would become tributary to this road, and there are few districts of like extent richer in mineral resources than this. Once built to this point there would, in fact, soon arise a necessity for continuing the road further south. As it progresses in that direction numerous brsnches would be built for the sccommodation of the mines that everywhere exist throughout these lateral ranges, and thus the entire country, now so isolated and difficult of access, would in the course of a few years he supplied with a system of cheap but serviceable railroads, of which this pioneer would become the grend trunk, connecting the whole with San Francisco, through the Central Pacific on the north, and through such other roads as may hereafter be built along more southerly routes.

This portion of the State has a great and prosperous future before it, and may well challenge the attention of capitalists and those already engaged or about to embark in railroad building. Land can here be had for nothing; surveys and the preparation of the road-bed need cost but little; the materials required from abroad can be brought in cheaply over the track already laid down. In a climate so dry and equable the superetructure will last a long time and can be kept in repair at small cost, while heavy grades, sharp curves and deep cuts would be a thing almost unknown The field is a broad and inviting one, and it will be strange if the opportunities it presents in thie line of investment are not availed of hefore long.

Cement in Cemeteries.

Now thst Guibord is finally buried, it is suddenly found out that no one takes any further interest in his bones. Those who were most determined that he should be safely buried assert that in all probability his grave will be robbed at an early day, but they evidently care very little whether it is robbed or not. On the other hand, the most enthusiastic of the Roman Catholics show no signs of intention to trouble themselves any further about the matter. The grave is to be thoroughly cursed; and inasmuch as Guibord's heretical boues are firmly imbedded in cement, they cannot permeate the rest of the cemetery with the pernicious doctrines that infected them during life. Besides, it would be a very difficult task to open a grave packed full of cement, and the French Canadian has no fondness for undertaking unnecessary work.

It would be odd if the desire to thwart the purpose of a religious mob should have resulted in solving the problem how to bury the dead with ssfety to the living. Guibord's coffin was surrnnded with cement merely as a precention against any attempt at disturbing it; it has already occurred to many minds that if coffins were to be uniformly imbedded in cement there would be no opportunity for the escape of pernicious gsses, and no possibility of the contsmination of springs of water in the neighborhood of graveyards. The evils connected with the ordinary methods of burial are constantly on the inorease, and senitary science is challenged to find some method nf opposing them. The expedient of burning the dead has evils of its own, in addition to the fact that popular prejudice is against it, and thst in many localities it would be simply impracticahle. There can, however, be no objection, on the score of sentiment, to filling the grave with cement, which will harden and enclose the coffin so olosely that the processes of decay will he to a great extent arrested, while at the same time all possibility of injury to the health of the community will be avoided.

The subject certainly deserves the attention of the sanitary authorities of our oities and large towns. If by so cheap and inexpensive an expedient as the uso of cement graveysrd csn be made no longer a source of danger to the public, the example set at the hnrial of Guibord should be adopted. There may be objections to it which are not ohvious to ordinary people. Still it certsinly seems as if the use of cement in cemeterics would fully meet the necessity of changing the present system of burial—a necessity which, year by year, is becoming more ohvious and imperative.—*New York Times.*

The Raymond & Ely Mine.

A correspondent of the *Chronicle* writes as follows concerning the Raymond & Ely mine: "That the famous Raymond & Ely mine of Nevada possesses great merit is evidenced by the data hereafter given and obtained from the books of the company. That its management is not being conducted in a commendable manner, hut somewhat after the Woodville style, is confirmed by the same data. This mine, since the 9th of June, 1875, has taken out and shipped to its officers in this city the sum of $452,482.50, as follows: In June, $98,447.53; July, $86,262.59; Augnst, $62,555.64; Septemher, $69,267.43; October, $74,086.12; November, $7,713.36; November 13th, $8,115.23; November 16th, $8,183.14; November 21st, $8,000; November 24th, $11,852; November 29th and 30th, $19,970. General Robert F. Morrow has now, and for a long time prior hereto, had the supposed control and management of this property. I do not for a moment question his integrity of purpose; still a lurking desire to lesrn the necessity of an assessment upon the stock of that company impels me to ask him for this information through the press rather than through the courts. I am a stockholder and willing to pay my assessment when required for the development of the mine, believing it to be of great velue; bnt I do not intend to replenish the private purse of any individual by way of assessment when the working of the property in which I have sn interest does not demand it. General Morrow, it is said, hes the control and mansgement of the Raymond & Ely mine. To work this mine when in full working order does not exceed the sum of $40,000 per month. An expenditure of $40,000 per month will employ 250 men at $4 per day, and give $10,000 per month, or more than $300 per day, for other expenses. Giving to the officers of thie company $40,000 per month for the working of the mine, there should remain in the treasury from the receipts of this mine the snm of $212,482. This mine may be in debt; if so, I desire to know the fact. It is reported that the Bank of California advanced to it the sum of $65,000. Concede it; still there remains the sum of $147,482, and no necessity for the present $3 assessment, particularly while the shipments therefrom continue, to wit: from $70,000 to $100,000 per month.

Hydrogen a Metal.—Scientists are gathering more and more proofs every day that hydrogen, or hydrogenium as it ie proposed to call it, ie a metal. Graham, who discovered its power of combination with iron, palladium and platinum, first considered it to be a metal, and now MM. Troost and Hautefeuille find that it combines with potassinm, sodium, nickel, manganese, lithium and thallium.

The Roberts' Island Reclamation.

The early and heavy rains of the present season bave materially interfered with the reclamation work now going on at Roberts' Island. This is hy far the most impnrtant, substantial and extensive work of the kind evor attempted in the State. The work has been laid out and carried on thus far under the general direotion of Mr. J. P. Whitney, well known throughout the Pacific coast as one of onr most energetio and enterprising men. Mr. L. C. McAfee acts ss his assistant and immediate snperintendent.

The entire work involves the constrnction of seventy-five miles of levee, divided into two sections, embracing what are known as the npper and lower sections of the island. The work on the upper section, embraoing about thirty miles of levee, was nearly completed when the unusnally high stage of water resched on Friday, the 19th inst., put a temporary stop to the same. The labor accomplished np to that time was most remarkable, considering the time which had been employed and the heavy and superior character of the work. We have seen and examined nearly all the reclamation works along the Sacramento and Sau Joaquin, hut hsve never seen anything equal to that which has been done under the direction of Mr. Whitney. If the rains had held off a few days longer, or if they had only come with the nsual amonnt of fall, the reclamation would hsve been complete and the water effectually shut out from the upper portion of the island; so thet almost or quite its entire area might have been put under cnltivation the coming summer. When we visited the locality on the Mouday after the water began to run over the hanks which were still unprotected, hopes were still entertained that the water might fall suffioiently to allow of the finishing of the work in sesson to save all the higher portions of the island from overflow. To this end all was being done that conld be, and work upon the contemplated improvements in the way of dwellings and barns was still progressing. As we have heard nothing from that quarter since, we are still in hopos the gap mey be closed and this important work of reclsmation be largely utilized the coming season; especially as we understand parties were ready to take leases to the extent of some 8,000 acres for a percentage of the crops, and enter upon the work of clearing np and plowing the land as soon as the levee was completed. These are considered among the most valuable tule lands in the State, and sre mnch more easily cultivated after the water is shnt out than lands further down the river.

While at the island we had the pleasure of seeing one of the "monster dredgers" at work building levee. These are the largest and most powerful of the kind in the world; only four of their size, we helieve, have been built, the two at Stockton and two others, one of which was sent to Japan. They work with a scoop which will lift from three and a half to four cubio yards of dirt at a lift, taking it from any depth from five tn thirty feet, and depositing it at any distance from directly alongside of the dredger to sixty feet beyond its center. One of these machines was put in position for work just before the rain commenced, and had thrown up a few hundred feet of levee before the wster rose, digging its own chsnnel as it progressed. While we were on board it was taken a short distance and put in position to close an opening which had been cut away by the high water in the natural bank of the river, and through which a perfect torrent was rushing toward the interior portion of the island. This break, which would have required the united efforts of many score of Chinamen for an entire day (even if they could have closed it at all) was effectually closed by this moneter dredger in less than fifteen minutes—thus demonstrating its vsst utility for such work in cases of emergency. It is proposed to largely utilize these machines in the work of levee building in the lower portion of the island, where operations will soon be commenced.

Japanese Perspective.—Thoughtless people, scrutinizing a bit of Japanese ware, sre diverted with what they are pleased to call "the comical lack of perspective" in the ornsment. The Jspanese artist does not undertake to produce aerial effects or linear perspective on plates, bowls, and vases. We must look to European art for such absurdities as landscapes and architectural drawings on spherical surfaces. In a Japanese workshop, the decorator *feels* jnst where a bright mass of color or a flowing line is wanted. He knows exactly where a single spot of gold or crimson will be most effective. He seems to have an intuitive eppreciation of the relation which color and line have to the general mass before him. Therefore he makes no mistakee. The bunch of brilliant azaleas, the flight of storks, or the floating butterfliee, are each placed where they belong on the object; with nnerring accuracy, eaoh ornament finds its true position in decorative art. The spece left undecorated is only an intellectual balance to the weight of color or mass on the other side. Precisely what geometrical rules determiue the value of these lines, or govern the disposition of masses, we mey not be ahle to say. But we may he sure that such agreeable, harmonious, and complete designs ae those furnished by Japanese artists, are the result of eerious etudy of certain fixed principles.—*Scribner.*

Useful Information.

Zinc as a Preventive of Boiler Incrustation.

Among the various means used of late for preventing scale in boilers is zinc introduced into the water space in ingots from one to two inches in diameter and about fourteen inches in length. We have made frequent use of it, and in many instances it has worked well, though we think its effects are different in different waters. An ingot of zinc of the size indicated above will disappear in from three to four months. We have made trial in nearly all the New England States and in some of the Western States, and we believe that in most cases it has shown good results. From what we have seen we are inclined to the belief that the iron of the boiler and the zinc form a voltaic couple, and that the water is sufficiently acid to excite galvanic action. The zinc is consumed, leaving an oxide well known to those who are familiar with the sulphate of copper battery, while the iron acts the part of an electrical conductor. The scale is rendered soft, porous and friable, and is easily removed from the boiler. We would not be understood as saying that this is true in all cases. We are of the opinion that the quality of water has much to do with the success of this method. Mr. J. F. Donoghue, of Springfield, Massachusetts, has devised and patented an anti-incrustator made by casting an ingot of zinc around a coil of copper wire. The ingot is flat on one side, and the coil is, consequently, only about two-thirds imbedded, leaving one-third to be acted upon by the water. Whether the introduction of a third metal, viz, copper, is an advantage, we are unable to say. But so far as we know, Mr. Donoghue's invention has worked well in most instances. We shall watch this method of treating scale, and report from time to time what our experience is.—*The Locomotive.*

Cork—The New Substitute for Leather.

The Paris correspondent of the London *Times* writes to that journal: A stall has lately been added to the Maritime Exhibition by the Cork leather company, for the purpose of showing a fabric which is very like leather, but with qualities not possessed by any animal's hide. It is well known that cork is the most brittle of barks, and yet, at the same time, the lightest of materials. The cork leather, which now makes its appearance for the first time, is simply sheets of cork covered on both sides with thin linen, but so prepared that when bent double it neither breaks nor cracks. What the solution is which produces this effect I cannot pretend to guess. If used as leather, it is certainly one-fourth the weight of hide, and looks as well, at half the cost. If in the guise of macintosh, it is as supple, and yet not sticky like ordinary water proof. Boots and shoes are exhibited of this material, but the most efficient use to which it can be put seems to be for military accoutrements and tent cloths. The French War Office has ordered a soldier's complete outfit to be made of the cork leather, and I understand that the Duke of Cambridge has directed similar samples to be sent to the Horse Guards. With regard to tents, the material is, without doubt, impervious to water, for this is practically shown at the Exhibition, while it is said on good authority to be superior to ordinary canvas in resisting heat. If it be used in the army the tedious burden of kit, belt and cartouche box will be very materially decreased. The inventor is a M. De Berski.

Boiling Felloes in Oil.

A correspondent of the *Hub*, a monthly publication devoted to the business, writes as follows: Having had some experience in the business, I will briefly state my views. Take a hard, close-grained piece of second growth hickory; the pores are small and filled with air, and, however dry, with a little water also. Put this in hot oil. The heat converts the water into steam, and expands the air so that is forced out of the timber, but I think very little oil goes in until the stick is taken out; then, as the remaining air cools and condenses in the wood, the air on the outside presses in what oil remains on the stick. The agitation or boiling that takes place while the wood is in the oil, is produced by the gas escaping, and not, as some imagine, by the oil penetrating the wood. I know that very little oil goes in, as I have boiled wheel after wheel in the same dish, and could see but little difference in the quantity of oil remaining. I think I could put on about as much with a paint brush. To put the thing to a practical test, I once took a set of wheels, boiled the felloes of two wheels in oil, and the remaining two left unboiled. I then painted them, and put them on a business wagon. When the tires needed setting, I tried to find the two boiled wheels, but failed to discern a particle of difference. The oil also loosens the spokes in felloes. I think just as good wheels can be made *without boiling* as with. We sometimes make use of the above process, however, to straighten felloes at the joints when they are bent too much.

Iron Bound.—The boundary line in the far Northwest is being marked by cast-iron pillars, eight feet high, set in the ground four feet, at distances of a mile from each other. The English and American governments set the posts alternately.

Sand Paper.—One of the old industries, the nature and extent of which are comparatively little known, is the manufacture of sand paper, the amount of which article annually produced in the United States is estimated at not less than 200,000 reams, including the various grades and qualities. Formerly it was made of ordinary brown paper, glue and sand. At present, for the most part, this paper is made of old rope, the best quality of glue is used, and, instead of sand, pulverized quartz or flint. By this means a superior fabric is produced, of a constantly uniform grade, and at so low a price that the use of it has become greatly extended, large quantities being exported to Europe, South America, the Pacific islands and elsewhere. For emery paper and emery cloth a large demand has been created by the finished iron works in steam engine shops, the sewing machine factories and other similar industries which require them for polishing purposes.

Anti-Friction Metal.—J. E. Gullatt, of Atlanta, Ga., has invented a car brass of anti-friction metal, which is said to be a superior article. One of these brasses has been in use on the Georgia road since July last, and run 13,000 miles with only one oiling. The pores of the metal absorb the oil and the friction draws out enough to lubricate it.

Utilizing the Heat of Burning Lime.—An enterprising and ingenious Irishman has patented a process by which the heat wasted in burning lime may be economized in the production of fruit and flowers under glass. At the top of the kiln is placed a boiler with hot water pipes connecting with the inside of a green-house.

The First Carriage.—Tains says that the first carriage caused much astonishment in England. Some said it was "a great sea shell brought from China;" others "that it was a temple in which cannibals worshipped the devil."

Dissolving Cotton and Silk.—The ammoniacal solution of oxide of copper will dissolve ordinary cotton fabrics and paper made of cotton. Silk is dissolved by the ammoniacal solution of oxide of nickel.

To Remove the Smell of Paint.—Hay sprinkled with a little chloride of lime and left for an hour in a closed room will remove the smell of new paint.

Good Health.

The Dangers of Anger.

An article by Dr. Richardson on "Induced Diseases from the Influence of the Passions," in the *Popular Science Monthly* for November, is interesting and instructive. He classes anger as the passion which stands first as being detrimental to life. He says:

He is a man very rich indeed in physical power who can afford to be angry. The richest cannot afford it many times without insuring the penalty—a penalty that is always severe. What is still worse of this passion is that the very disease it engenders feels it, so that, if the impulse go many times unchecked, it becomes the master of the man.

The effect of anger upon the brain is to produce first a paralysis, and afterward, during reaction, a congestion of the vessels of that organ; for, if life continues, reactive congestion follows paralysis as certain as day follows night. Thus, in men who give way to violent rage, there comes on during the acute period what to them is merely a faintness, which, after a time of apparent recovery, is followed by a slight confusion, a giddiness, a weight in the head, a sense of oppression and a return to equilibrium. They are happy, who, continuing their course, suffer no more severely.

Many die in one or another of the two stages I have named. They die in the moment of white rage, when the cerebral vessels and heart are paralyzed. Then we say they die of faintness after excitement. Or they die more slowly when the rage has passed and the congestion of reaction has led to engorgement of the vessels of the brain. Then the engorgement has caused stoppage of the circulation there, or a vessel has given way, or serious fluid has exuded, producing pressure, and we report that the death was from apoplexy, following upon some temporary excitement.

Swallowing a Cent.—Dr. Gibbs, one of the editors of *Hall's Journal of Health*, who is himself an educated physician and surgeon, while on a railroad train, the other day, was consulted by one of the employees on the cars in relation to his little boy, who had that morning swallowed a cent. "What have you done for him?" asked the doctor. "We gave him a dose of castor oil," was the reply. "Good practice, so far; as soon as you reach home give him the whites of three raw eggs daily, let his diet be bread and milk, and *nothing sour.*" The directions were followed faithfully, the whites of the eggs repeated every day, and the dose of castor oil at night and on the fourth day the cent was discharged. It was one of the new copper coins, and considerably corroded by the action of the gastric juices. Since fatal results often follow the swallowing of copper coin, the judicious treatment advised in this instance should be remembered by all who have the care of children. The essential points to be borne in mind are simply these: albumen, or the whites of eggs, a bland diet free from acids, and castor oil.

Give the Children Candy.

Dr. L. P. Meredith, of Cincinnati, a skillful and successful dentist, has lately published an excellent little pamphlet on "Our Teeth and Their Preservation." Boys and girls who love candy—and which one does not—will rise up and call the doctor blessed on learning that he declares sugar to be "not only not injurious to the teeth, but that it is really beneficial to the health of the child." In support of this statement he cites a number of eminent witnesses. Henry, Duke of Beaufort, for forty years ate nearly a pound of sugar candy daily, and yet died at the age of eighty, with a full set of perfect teeth in his head. Cleland, in his "Institutes of Health," mentions a Mr. Mallory, who was extremely fond of sugar and addicted to its use, and who reached the ripe age of one hundred years, having good teeth until he was fourscore, and then actually cut a new set!

In the "Code of Health and Longevity," by Sir John Sinclair, it is affirmed by Dr. Slare, that his father lived to be a centenarian, and was in good health and strength until the day of his death, while his teeth were sound and strong up to the age of eighty. This healthful condition of body and teeth was ascribed by Dr. Slare to the liberal consumption of sugar, which his grandfather ate not only on his bread and butter, but in his ale and beer, and in all the sauces used with his meat. In addition to this testimony, the entire race of negroes dwelling in sugar countries may be brought forward. They eat sugar without stint, the little ones almost living upon it during the sugar season, and yet their teeth are remarkably white and sound. Teeth have stood this test of being immersed for a year in a bath of syrup without being in the least affected. "So," says the doctor, "don't deny sugar and candy to the youngsters, and recollect that while they are ramming their sugar coated fists down their throats and yelling for more, and are plastering the legs of your piano and sticking the pages of your photograph albums together, they are on the high road to the conservation of health, and let them alone. But don't let them injure their teeth by biting very hard candy; and clean their teeth for them, for, after acetous fermentation has taken place, sugar is just as injurious as other articles of food, but no more so."

Dangers of Port Wine.—Port wine is more used than any other kind of wine by the sick; and as it is also a wine more adulterated than any other, people should be extremely cautious as to what they are using. A new adulteration of this wine has recently been introduced, which is in some cases dangerous, especially when partaken of by feeble or delicate persons. It is an artificial coloring, consisting of a mixture of azalin and magenta red. The aniline colors, objectionable in themselves, are the more dangerous because they not unfrequently contain arsenic. The adulteration is detected by shaking the suspected wine (and all cheap wines are to be suspected) with an equal volume of amylic alcohol (fusel oil). If the wine is genuine port, the amylic alcohol remains colorless; but if adulterated, it dissolves out the coloring matter, and itself appears of a purple red color.

A Man Pulls His Own Tooth and Nearly Bleeds to Death.—Recently, Mr. Harbold, of Amity township, Berks county, Penn., found one of his teeth troubling him very much, and not having either the time or the inclination to send for a dentist or physician, concluded to remove the molar himself. He armed himself with such instruments as were at hand, and finally managed to get the tooth out, but with it came a large piece of bone. This was bad enough, but he soon found that during the operation he had severed an artery, and was in a fair way of bleeding to death. Dr. R. B. Rhodes was sent for, and after some trouble finally succeeded in stopping the great flow of blood, and again setting Mr. Harbold to rights.

How to Float.—Men are drowned by raising their arms above water, the unbuoyed weight of which depresses the head. Other animals have neither notion nor ability to act in a similar manner, and therefore swim naturally. When a man falls into deep water he will rise to the surface and will continue there if he does not elevate his hands. If he moves his hands under water, in any way he pleases, his head will rise so as give him free liberty to breathe; and if he will use his legs, as in the act of walking (or rather walking up stairs), his shoulders will rise above the water, so that he may use the less exertion with his hands, or apply them to other purposes. These plain directions are recommended to the recollection of those who have not learned to swim in their youth, as they may be found highly advantageous in many cases.—*The Sanitarian.*

A Singular Accident.—A singular misfortune has overtaken a young man at Halifax, N. S., which may result in the loss of his life. It seems that while he was picking his teeth with a straw a piece of it lodged between two teeth in such a manner that he could not get it out. It annoyed him for several days but finally the pain ceased, and he found that the straw had worked under his tongue, where it soon began to cause pain, and at last resulted in the tongue becoming swollen and inflamed, while symptoms similar to those of diptheria appeared in his throat. He at once sought medical advice, but his case is now considered very critical.

Domestic Economy.

Nutritive Value of Cocoa.

The nutritive constituents of cocoa correspond very closely with those of beef, and largely exceed those of milk and wheaten flour; hence the importance of this substance as an article of food. In this respect it differs widely from tea and coffee, which are, perhaps, rather condiments and stimulants than foods, or flesh-formers. The following table, drawn up by Mr. John Hollm, of the Edinburgh chemical society, shows the position of cocoa as compared with three other well known articles of food:

Articles.	Cocoa	Milk.	Meat. (Beef)	Wheaten Flour.
Fat	50.0	3.5	2.87	1.2
Azotized substances	20.0	4.0	20.75	14.6
Starch	7.0	.....	.....	59.7
Gum	6.3	.....	.....	.....
Sugar	.....	4.3	.....	7.2
Water	5.0	87.5	67.80	13.2
Salts	4.0	.7	5.60	1.6
Woody fibre	4.0	.....	.....	.....
Cellulose	.....	.....	.....	1.7
Coloring matter	2.0	.....	.....	.....
Ash	.....	.....	1.60	0.8
Extractive matters	.....	.....	1.30	.....
Theobromine	2.0	.....	.....	.....
Parts	100.0	100.0	100.00	100.0

Thus, although one-half the weight of cocoa consists of cocoa-butter, it still presents 20 per cent. of albuminoid material, as against 4 per cent. in milk, 20.75 in beef, and 14.6 in wheat. In addition it contains starch, which is present neither in milk nor beef, but in smaller proportion than in wheat. The value of cocoa as a food is thus apparent, and fully justifies the high eulogiums which have been passed upon it.—*Pop. Science Monthly.*

Onions.—It is admitted that the majority of people like onions as food, and, only for the perfume, many would eat them who now do not. The unpleasant breath which eating this vegetable produces is perhaps the greatest objection to its use, but still it is a very wholesome and desirable article of food for many, and hence should be brought on the table in the most attractive form. White onions, and those grown in the South, are less odorous and pungent. Take off the outside skin, cut off both ends close, and let them stand in cold water an hour, then drop them into a saucepan with two quarts of boiling water. Cover, and boil fifteen minutes. Have a kettle of boiling water on the fire ready for use, pour off the water from the onions, and add as much more—be sure the water is boiling—and boil half an hour longer. Scald a cupful of rich milk and a little graham flour to thicken it. Salt and otherwise season to taste. Boil up a few minutes and serve the onions whole; or they may be cut in halves before cooking. That they are antiscorbutic as well as antiseptic is also admitted, and this is the way they should be prepared for such use: A few moments before eating they should be sliced quite thin and sprinkled with sugar, and you have a palatable relish which will not rise on the stomach or produce heart-burn.

Fruit Juices.—The juice of the apple and pear, says Mr. Knight, may be used to great advantage in preparing a beverage. He has frequently, he says, reduced it by boiling to the consistence of a weak jelly, in which state it has remained several years without the slightest apparent change, though intentionally exposed to variation of temperature. A large quantity of the inspissated juice would take up but little space, and the addition of a few spoonfuls to a quart of water would at any time form a delicious, wholesome, refreshing drink, free from all intoxicating properties. Its cheapness would be greatly in its favor. On sea voyages it would be a great luxury. We suggest experiments with it in the field of domestic economy.

Boiled Rice.—Wash and drain off one pint of good new rice; put into a covered saucepan with one quart of boiling water. Boil briskly for five or ten minutes, or until the water is mostly absorbed; then set on one side of the stove, and let it steam steadily fifteen or twenty minutes. Keep closely covered all the time, and do not stir it at all after it begins to boil. The Southern people, who know both how to cook and to eat rice, never allow the lid to be removed while the steaming is going on; perhaps just lifting one side of the cover to peep in, and see that it does not burn. When done just right, every grain will be swelled to its utmost, and bursted open. To be eaten as a vegetable, or with cream or maple syrup.

A Delicious Cracker.—Take equal parts "middlings" and graham flour. Wet with new or sweet milk, and knead rather stiff. Work it a good deal on the board; then roll out to one-quarter of an inch in thickness, and cut out in diamonds or squares; prick them, and bake in a quick oven. Bake best right on the grates.

Codfish.—The best way to cook codfish is to strip it of its skin and cut in pieces about the size of one hand; place it in water and allow it to simmer on the stove until it becomes tender. It should never be allowed to boil, as boiling hardens and darkens the fish and deprives it of its flavor.

MINING AND SCIENTIFIC PRESS.

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, GEO. H. STRONG
W. B. EWER, JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week.	1 month.	3 months.	1 year.
Per line..... .26	.80	$2.00	$5.00
One-half inch.....$1.00	3.00	7.50	24.00
One inch..... 1.50	4.00	12.00	40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the PRESS promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

San Francisco:
Saturday Morning, Dec. 11, 1875.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Triple Cylinder Engine; Alden's Ore Pulverizer; Notices of Recent Patents; A. J. Doolittle, 369. The Geological Survey; Death of J. Ross Browne; The New Almaden Continuous Furnace; Academy of Sciences, 376. The State Legislature; Sierra County Diggings, 377. The Concentrating Works at Falun in Sweden; California Tobacco; Patents and Inventions, 380.

ILLUSTRATIONS.—Triple Cylinder Compound Balance Piston Steam Engine; Alden's Ore Pulverizer; 369. The State Capitol Building at Sacramento, 377.

SCIENTIFIC PROGRESS.—Artificial Production of Organic Bodies; A Physiological Problem; Power of Gunpowder; The Andes Gradually Sinking; Fermentation from Inorganic Substances; Action of Heat on Coal; Storms Crossing the Atlantic, 371.

MECHANICAL PROGRESS.—Injurious Effects of Snow on Steel Rails; The Brayton Oil Engine; Curious Electrical Phenomena; Belting vs. Frictional Gearing; Patterns for Scroll Work; The Bastic Glass; Steel Ships; Trning Oilstones, 371.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 372.

MINING SUMMARY from various counties in California and Nevada, 372-3.

USEFUL INFORMATION.—Zinc as a Preventive of Boiler Incrustation; Cork—The New Substitute for Leather; Boiling Felloes in Oil; Iron Bound; Sand Paper; Anti-Friction Metal; Utilizing the Heat of Burning Lime; The First Carriage; Dissolving Cotton and Silk; To Remove the Smell of Paint, 375.

GOOD HEALTH.—The Dangers of Anger; Swallowing a Cent; Give the Children Candy; Dangers of Port Wine; A Man Pulls His Own Tooth and Nearly Bleeds to Death; How to Float; A Singular Accident, 375.

DOMESTIC ECONOMY.—Nutritive Value of Cocoa; Onions; Fruit Juices; Boiled Rice; A Delicious Cracker; Codfish, 375.

MISCELLANEOUS.—The Mineral Resources of Mexico; The Golden Enterprise; Groom District; Sheriff's Sale; The O'Hara Furnace; Pump Accommodation; The Signal Service; Copper Mines in Utah; The Ridge Lead; Fast Horseback Riding, 370. Improvements in Central Nevada; Cement in Cemeteries; The Raymond & Ely Mine; Hydrogen a Metal; The Roberts' Island Reclamation; Japanese Perspective, 374.

BAD LUCK.—We nnderstand that the Oak Ranch mining company, near Enreka, Sierra county, after expending $14,000 on their diggings, waehed recently fonr hnndred cart loads of gravel, realiziug the handeome (?) snm of $3.75 in coarse gold, which has been carefully eealed up in a bottle, and the boys say it will be eent to the Centennial as a most vivid illnstration of miners' bad lnck. In most other parts of the county the miners are doing well, and thie is an exceptional case.

THE NIAGARA.—A meeting of the investigating etockholders of the Niagara mine was held laet Saturday night. A report was presented from the investigating committee, who said that the mine had been cloeed for ninety days, and that if the stockholders desired a change in the management, they must unite in giving their proxies to one person to have a meeting of the stockholdera called. It appears that only 26,000 shares have yet been subscribed in favor of a change in the management. The list ia to be kept open for two weeks longer.

THE Regents of the State University by a formal vote have accepted the donation of Mr. Liok of $750,000 for a telescope, and a committee haa been appointed to wait on Mr. Lick and return thanks for the Board.

THE heavy storma have washed ont the tailings in all the creeks and ravines so that the miners have plenty of fall, and enables owners to rush things as fast as they choose.

The Geological Survey.

Among the matters which shonld come prominently before the Legielatnre during the present session is the consideration of reeuming our partly finished geological survey. The matter is of no little importance and cannot be discnssed too soon. At this time, when the air ie rife with plans and echemes to be enbmitted for the action of the Legislatnre, some steps shonld be taken to bring before them the snbject of the resnmption of the survey. The progress of the survey np to the time of its discontinuance called forth mnch commendation from the scientific world, and added largely to the reputation of California as a field for scientific research. Bnt the people became dissatisfied both with the chief and the method of the snrvey. Practical results we arrived at soon enongh, and it wae thonght that the head of the survey dieregarded the wishes of the people in not publishing one or more volumee of economic geology, embracing the principal mineral regions of the State, accompenied by maps and illustrations, and giving snch nseful generalizetions, tonching our great leading indnstry of mining—particnlarly that portion of it connected with onr immense gravel deposits end ancient rivere—as would be of immediate practical benefit to the people.

The survey was stopped by the Legislatnre refusing to make any appropriation, and the material was torned over to the Univereity. It is well known that a large amonnt of material hae been collected from which valnable pnblioetions could be prepared, and the chief objection to the snrvey having been removed, by ita head being displaced, there is now no reason why the material could not be utilized and the survey go on again. It is certainly a great shame that ao much material and labor ehould be waeted, and that a partly completed survey of as rich a State aa California should be entirely stopped. The great benefit to accrue to science and to the State from the completion of this survey is recognized and acknowledged by all. Many of the very men who voted against the appropriation hoped to see the anrvey resumed at some futnre time. The method and the chief can easily be chauged.

Thia ia no scheme to be met with jealousy or aversion by politicians of either party. The material advantages to California would aoon compeneate for all ontlay. The etrategraphical arrangement of the rocks on thie coast is altogether unneual and peonliar. The great development of the cretaceoua formation, carrying as it doee our Pacific coast coal measures and all the large quicksilver deposits, is one of the nniqne features of this coaet. The proper definement of this formation together, with the great pliocene gravel deposits in which so much of the hidden wealth of California is stored, wonld of itself repay many times over the neoessary ontlay.

Tho Academy of Sciences of this city is taking the initiative to bring this subject prominently forward. Mr. J. R. Scupham introduced the matter at the laet meeting, and a committee has been appointed to consider ways and meana. Should the appropriation be voted this winter it would still take some time for the survey to be organized and we cannot afford to wait two years moro for this to be commenced.

The New Almaden Continuous Furnace.

We append a table showing the work of a new continuons quicksilver furnace rnnning since the 4th of Mareh last at the New Almaden mine in Santa Clara connty.

	Pounds of ore roasted.	Flasks Quicksilver produced. Free	From Soot.	Total	Per-cent age.	Cords Wood hnrned.	Charco'l & Coke hurned, pounds.
Mar	501,800	449	21	470	7.17	19½	5,866
April	676,000	503	23	526	6.98	20¼	8,640
May.	595,200	738	29	767	9.85	22	8,928
June	676,000	713	31	744	9.88	20⅞	8,640
July	793,600	810	52	862	8.31	24½	11,904
Aug	608,000	658	41	699	8.78	22½	9,120
Sept	676,000	744	23	767	10.18	22½	8,640
Oct	595,200	862	29	891	11.45	25	8,928
Nov	576,000	1,066	46	1,112	14.76	24½	8,640

The general manager, Mr. Randol, who furnishes ns the above figures, etates that this furnace is the "champion" eo far as he knows.

LIEUT. J. H. WEEDEN, of the United States Engineers, ie making surveys for tnrning the San Diego river, having obtained the right of way through private land. Shonld the weather continne favorable he will commence work at once.

ANDREW CASAMAYOU, senior editor of the *Reese River Reveille*, died at Austin, Nevada, on the 7th inst.

THE Manhattan silver mining company shipped bullion valued at $32,000 from Austin on the 7th inst.

ABOUT two hundred men are employed upon the Santa Clara and Alviso narrow gauge railroad.

A LARGE bed of asphaltum has been discovered in Santa Barbara county.

SINCE '49 the month past was the wettest November.

Death of J. Ross Browne.

J. Ross Browne, who has been closely identified with the mining and general interests of California, died enddenly at his residence in Oakland on Wednesday last. Mr. Browne's name is widely known, both from the prominent positione he has held, and from his literary work. Hie travels have been very extensive, nnd as he wae an observing man, his written accounts were inetructing and amusing.

Mr. Browne was a native of Ireland, but was bronght when a child to Kentucky. When nineteen years of age he went to Waehington, and being a good stenographer, obtained a sitnation as reporter in the Senate. His desire to travel was so great, however, that in 1842 he started with a friend for a tonr of Europe, intending to trust to their wits for support, as the joint capital amounted to the modeet eum of $40. Shortly after landing in New York they fonud their money and their chancee of reeching England redneed to a minimum, and being adverse to asking assistance from their friends, fell into the hande of a shipping agont, who hnmbugged them into signing articles for a whaling cruise. They left the ship at Zanzibar and remained there eix months. Mr. Browne retnrned then to America, and became private secretary to R. J. Walker, Secretary of the Treasnry, retaining the position until 1849, when he came to this State by a sailing veesel arouud the Horn, to report the debates and proceedinge of the convention called to frame a Stets Constitntion, then eitting at Monterey. He retnrned to Washington, and after a short sojouru in that city went to Europe, in 1851, as correspondent for several newspapers. After an extended tonr throngh Southero Europe and Palestine, Mr. Browne again turned hie steps toward America, and received at once an appointment as Inspector of Lighthouses on the Pacific coast. In 1861 he vieited Europe for the second time, principally for the benefit of his children, for he had been married meanwhile. Leaving his family at Frankfort-on-the-Main, the seeker after novelty journeyed to thonorth, having first taken a peep at Algeria, and travelled extensively through Ruseia, Poland, Norway and Denmark, Sweden and Iceland. On his return to this country the Government employed him to examine and report upon the mineral resources of the region west of the Rocky mountains, and in 1868 he wae appointed by President Johnson, Minieter to China. This poaition he held until 1870, when he reeigned and retnrned to California, and has aince resided qoietly at his home in Oakland.

Mr. Browne is, perhaps, best known among the mining community hy hie work on the "Reeonrces of the Pacific States and Territories," tho first of a series of reports on the mining industry, published nnder government anspicea. Aa an author hewas amusing and instructive. His earliest published work was, "Etchings of a Whaling Cruise, with Notes of a Sojourn on the Island of Zanzibar." Among his other works are "An American Family in Germany;" "Adventuros in the Apache Country;" "Land of Thor," "Crusoe's Island;" "Yueef;" "Travels in the East." For many years he contribnted articles to *Harper's Magazine*, which were eo bright and charming in their style that they were greatly inatrumental in the snccesa of that periodical. His Washoe experiences, which appeared in that magaziue, will be remembered hy many. He hns, for many yeara, been identified with the intereste of California, and labored hard to foster and uphold them. He bore an unblemished reputation, and had a large oircle of warm frienda. He leaves a wife, aix children and several grandchildren to monrn his loea.

A FRIGHTFUL FALL. — On the 7th inst. a miner named J. .Town, employed in the Oregon mine, at Eureka, wheeled a car from the 390-foot level into the shaft, and fell with it to the sump, a distance of 400 feet. Men engaged at the 59-foot level, hearing the noise of the fall, ran to the station of that level, when Town hailed them and aeked them to lower a rope, telling them that he waa clinging to the guidee and that he believed he was strong enough to come np without assistance. The request was complied with, bnt after being hoisted fifty feet Town cried ont to the men above to lower him quickly as hie hold was weakening and that he felt faint. Two miners then went dowu to his assietance, and he was bronght to the snrface; his mouth waa fonnd to be filled with blood, but beyond thie and a sensation of pain in the region of the back there were no indications of hie being injured. The phyaicians state that the man has not sustained fractnre of any bones, and that nnlese he hae received internal injuries he will recover. He made the frightful deacent of npward of 300 feet down the shaft while clinging to a loaded car. Since the above was written the telegraph informs us of Town's death.

THE President'a mesange, Governor Pacheco'a farewell, ex-Mayor Bryant's salutatory, ex-Mayor Heuston'a valedictory, and Governor Irwin's necessary ioaugural, are so many state papere of importance whioh came upon ns at once, that we are unable to do juetice to them all.

A COLLIERY explosion at Barnaley, England, on Wednesday, was the oause of the loss of 140 lives.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Mondey evening last. A very large nnmber of donatione to the cabinet were received, emong them an extensive collection of California woode, end a number of native fishes not hefore in the collection of the Academy. Dr. Harkness presented a map donated by General Stone through General Purdy, showing the work done by American engineers in Africa for the Egyptian Government, in the course of a enrvey. W. N. Lockington then read a paper descriptive of fishes, presented to the Academy at the laet meeting. Mr. Lockington aleo read a paper on landscape gardening, giving some views as to the proper ornamental plants aud shrubs to plant in onr gardens.

A peper on "New Facts Releting to California Ornithology" was submitted for publication.

Mr. Dameron stated that he had been making some investigations in relation to the propagation of oysters, and thonght that he had diecovered a method which he thought wonld he of value to preeerve the epat and cauee the Eastern oystere to propagnte here. He wonld deecribe his discovery at some future meeting.

Mr. J. R. Scupham made a propositiou for the academy to aid in the resumption of the Geological Survey. Since it was the object of the academy to forward the intereet of science, it would be very appropriate for it to take the initiative in the matter. In no one thing could it do more for science than to have this great work resumed. A committee, consisting of J. R. Scupham, Dr. Jas. Blake and Wm. Ashburner, was appointed to examine into the matter and report at the next meeting.

The Late B. P. Avery.

Robert E. C. Stearns made some feeling remarks on the death of the Hon. Benjamin P. Avery, of which the following is a brief enmmary: Siuce our last meeting the telegraph hss brought us sad newa—information of the death of our follow member, the Hon. Benjamin Parke Avery, U. S. Minister to China, who died in the early part of November, at the city of Peking. The many excellences of the deceased, the co-operative apirit whioh he ever manifested in all matters pertaining to the welfare of his fellow men—qnietly becauee he was singularly modest and undemonstrative, yet nevertheless peresistently pnrsning the eveu tenor of what he conaidered his duty—and that duty the advancement of civilization in a new State, the promotion of knowledge, whether literature, science or art, and the general refinement and elovation of the commonwealth in which he had made his home; euch qualitiee and such aervices make it eminently proper that we ehould inscribe on the permanent records of the academy au appreciative recognition of his life and labors, as well as an appropriate expression of our esteem and of our aorrow for his loea. With the example of his unassuming but honorable career before us—too brief but yet well filled with nseful work—it would he in discord with its harmony to expand theee remarks into formal enlogy * * * Thoee who knew him beat, and who enjoyed the precious freedom of intimacy, will tell yon thet his life waa conapicuoua for its purity, his character for its many virtues, hia intellect for its refined and delicate culture, his heart for its tender and generoua sympathy. The poseeesion of these qualitiea endear a man to hia fellow men; they constitute a charming whole, whoss priceleas wob is woven from the graces of our poor humanity; they form an enchanted mantle, whose shining folde hide the poverty of hnmeu limitations. So lived aud walked our friend among us, crowned with the affection aad esteem of all who knew him; I canuot say that he was perfect, and yet if fault he had, I knew it not uor ever heard it named. Hore let us rest—gratified that so true a life has beeu e part of ours. We place our tribute on his grave, and say, good friend—farewell.

The followiug reaolntions were adopted:

Resolved, That the California Academy of Sciences has learned with profound regret of the death of Hon. Benjamin Parke Avery, a member of this academy, and late U. S. Minister at the court of Peking; that we hereby recognize and express our high appreciation of his many private virtues and public services.

Resolved, That these resolutions he spread on the records of the academy and published in the proceedings.

THE Salines quicksilver mining company has aold to San Francisco partiea for $4,000 the privilege of mining for antimony in two of their several claims in the Stayton district, near Hollister.

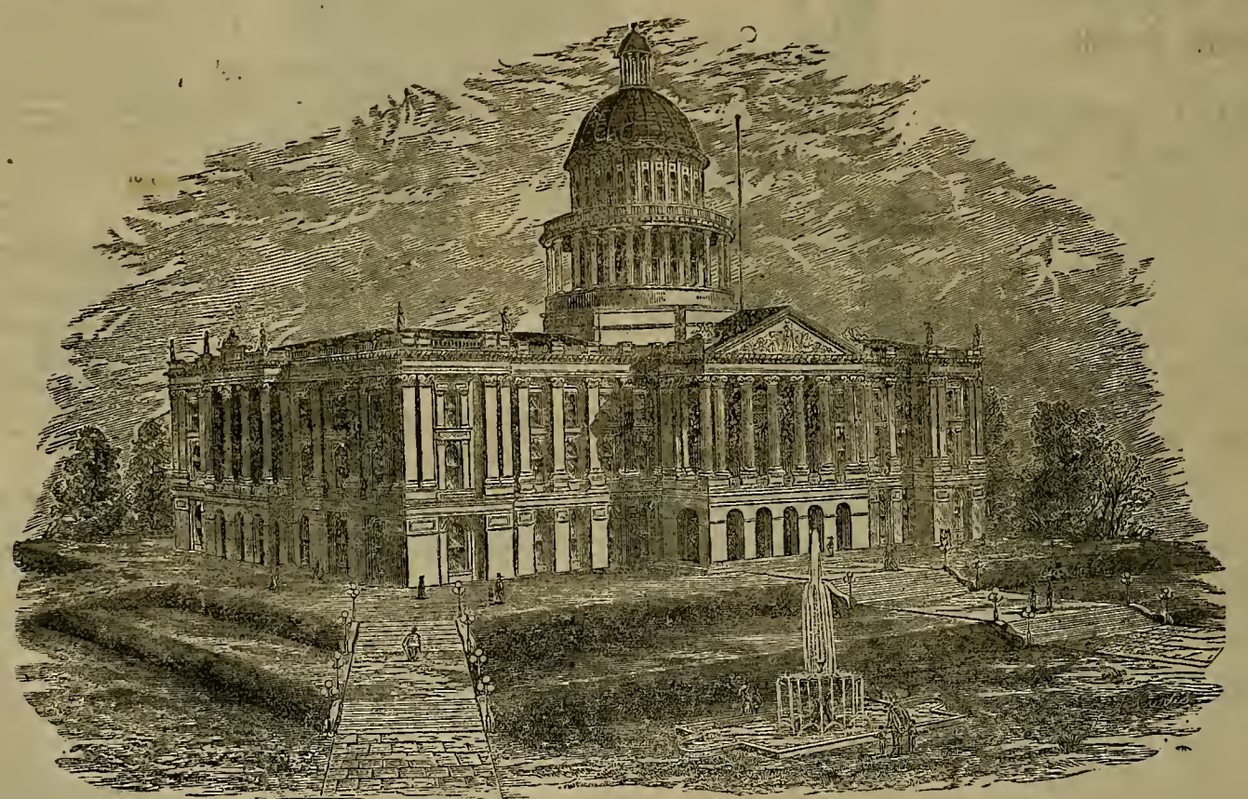
THE manufacture of atone paving blocks in the vicinity of Petaluma ia becoming an important industry. Ahont 700,000 blocks have been made the past year—valned at over $60,000.

THE control of the Kentuck mine, on the Comstock, has paesed into the hands of Senator J. P. Jonea and his aasociates. Samnel L. Jones haa been elected snperintendeut.

THE Board of Aldermen of Virginia City, have finally determined that the crosa streets in the burnt district ehall remain of the same width as previous to the fire.

The State Legislature.

The Legislature of the State of California convened at Sacramento on Monday last, and we consider this an appropriate time to present to our readers a representation of the magnificent State capitol building provided for our law-makers while in session. The building itself is a large and imposing structure of stone, brick and iron, 320 feet in length. Approaching it from Tenth street, it may be regarded as a great central building, from which rises the lofty dome, and having on each side a large wing. The first story of the center is granite, with five arched entrances. The Corinthian columns and pilasters shown are massive and elegant. Several large figures ornament the front above the columns, representing war, science, agriculture and mining. Above this the body of the main dome is surrounded by an open balcony, which is supported by twenty-four columns. Above the balcony the body of the dome is supported by an equal number of ornamental pilasters. From there rises the great metallic dome. From the top of this dome in turn rise twelve Corinthian columns which support the final or small dome, and this is surmounted by a ball. At each prominent point on the building is a colossal statue, giving a fine finish to the structure. From the top of the dome a most magnificent view is seen, and it is well worth the trouble of climbing the 208 steps from the hall floor to get a bird's eye view of the surrounding country.



STATE CAPITOL BUILDING, SACRAMENTO.

The interior of the capitol is in keeping with its external proportions and appearance. In the north wing is the Representative chamber; in the south that of the Senate; between the two is the State library. The library is circular in form, surmounted by a dome supported by twelve beautiful columns. It is divided into nine alcoves radiating from the center, elegantly fitted up. The remainder of the building is occupied by the various State officers. The workmanship in the interior is very fine and costly. Beautiful woods are used in its construction, and everything is of the best quality. The grounds occupy four blocks and form three terraces slightly elevated above each other, and connected by broad and easy flights of steps. They are at present in fine condition, the lawn being closely and smoothly trimmed, and the shrubs and evergreens in good order. The capitol is, in fact, something for the legislators and the people to be well proud of, and is well adapted for its purposes.

As a matter of general interest we take from the Sacramento *Record* a list of the members of the Senate and Assembly that constitute the Twenty-first Legislature, as made out from returns received at the office of the Secretary of State, including hold-over the Senators. The hold-overs are designated by an asterisk (*); the names of Republicans appear in Roman, those of the Democrats in *italic*, and those of Independents in SMALL CAPITALS, while Democrats who were elected independent of any party are indicated by the initials "I. D."

Senate.

First District—Counties of San Diego and San Bernardino—J. W. Satterwhite. (I. D.)

Second District—Los Angeles—C. W. BUSH.

Third District—Ventura, Santa Barbara and San Luis Obispo—*W. J. Graves.*

RECAPITULATION.—Senate—Democrats, 24; Independents, 10; Republicans, 6. Assembly—Democrats, 62; Republicans, 9; Independents, 8; one tie between a Democrat and Independent. Totals—Democrats, 86; Independents, 18; Republicans, 15, and 1 in doubt

On Tuesday the election of officers of the respective houses took place, with the following result:

Officers of the Senate.

B. F. Tuttle, president *pro tem.*; for secretary, J. J. Shackleford; assistant secretaries, F. J. Clark and E. Crawford; sergeant-at-arms, J. W. Hawkins; assistant sergeant-at-arms, J. B. Snyder; enrolling clerk, W. F. Howell; engrossing clerk, P. H. Ryan; journal clerk, General Crosby; minute clerk, Newton Benedict; copying clerks, E. Gallagher and J. Conoway; porters, H. Klock, James Watson and B. McMurray; pages, H. Jacobs, H. M. Edwards and W. B. Doland; postmaster, J. C. Berniston; postoffice page, John F. Parsons; paper folder, John M. Kilgariff; night watchman, James Saltry; rear porter, Hawk Jones.

Officers of the Assembly.

Speaker, G. J. Carpenter; speaker *pro tem.*, J. A. Murphy; chief clerk, Robert Ferral; assistant clerks, William Ord and Chas. O'Neil; sergeant-at-arms, Dana C. Perkins; assistant sergeant-at-arms, T. O'Connor; minute clerk, J. W. McCarthy; journal clerk, J. M. Martin; copying clerks, T. C. Morris and J. G. Rogers.

We shall, during the session of the Legislature, give considerable attention to such measures as are of general or special interest to the readers of the Press; and such laws as affect them nearly will be given in full. At the same time, without presuming to offer advice or attempting to dictate, we shall bring before the attention of our legislators the views of the industrial classes whom we represent, on all matters which affect their interests. Many questions of great importance will of course arise during the present session, which will be widely discussed. As representatives of a large and progressive class of the community, we shall take occasion to comment on the measures proposed in a free manner, without any party distinction whatever.

Sierra County Diggings.

There is an abundance of water every where throughout the northern part of the State, and lively times are expected among the miners. A correspondent writes us from Sierra county that a large number of claims at Gibsonville, Howland Flat and Port Wine are expected to pay well this year. At Eureka, the boys on the claims are all washing and taking out pay. At Mt. Pleasant ranch, the Iowa company's diggings are nearly clear of water, working steadily with good prospects. The shaft is 301 feet deep.

At Gibsonville, the Pen Haven gravel company's main tunnel is in 700 feet, and they will soon be ready to take out pay. The Union, Boot Jack and Chalcedony companies are putting in great improvements on their claims.

At Howland Flat, the Fashion Co., Cold canon, is paying very well. Five men took out 17 ounces last week, and the ground seems steadily to increase in richness. The Empire Co. are taking out large amounts of gold. Forest City is crowded with miners from Virginia and other parts of the country, looking for work. The Bald Mountain Co. are washing now, and taking out lots of gold. The North America Co., at Hepsidam, are washing, and reported as doing well.

The Rising Sun Co., Mt. Vernon, adjoining the Green Mountain, and supposed to be equally as good, between Downieville and Forest City, cleaned up during the past fifteen days 24¾ ounces of average coarse gold, with only three men at work.

THE Baltimore and Ohio railway company announce a drawback of three cents per hundred pounds on all grains brought to Baltimore from Western points which passes through their elevators for exportation to foreign ports.

AN application will be made to Congress for an appropriation of $200,000 for a breakwater at Santa Monica.

SAVE YOUR HORSE'S FEET!

NO MORE RASPING AND HAMMERING TO CLINCH HORSE-SHOE NAILS. TENDER FOOTED HORSES SHOD WITH EASE. EVERY TEAMSTER HIS OWN BLACKSMITH.

The new patent implement used is an attachment to an ordinary pair of pincers. A scoop-shaped graver, or chisel, and a flattened, roughened plate, (formed in one piece) are hinged and fastened on to the handle of the pincers. When the forceps are closed the graver projects from one side of the handle, and is retained in that position by allowing the end of the plate to enter a slot between another plate on the other handle, and the handle, thus holding the graver steadily, while the forceps are grasped by both hands, and the grooves cut in the hoof below the point where the nails come through. When the grooves are cut the handles are opened, and the roughened plate turned outward, thus carrying the graver into a slot in the socket, out of the way.

To clinch the nails after the grooves are cut, the handles are opened, and the roughened plate is put beneath the hoof. The edge of a steel plate on the handle of the forceps is then placed above the nail point, and by closing the handles the nail will be bent down into the groove already cut, where it lies nearly flush with the hoof. The plate can be adjusted for large or small hoofs. The groove cut by the graver is about one-eighth of an inch long and one-eighth of an inch wide. No hammering or rasping is necessary. The foot is not bruised or scarred. Any one can learn to use it in a few minutes. Tender-footed horses can be shod with no pain to them. Further information given, if desired, by CARLES R. DONNER, Inventor, or C. F. SUHL, Cor. Commercial & Drumm Sts., S. F. eowbp

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.

It is unequalled for cleansing Woolen Fabrics, Cutlery, Carpets or Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing.

It renders water soft, and imparts a delightful sense of coolness after washing.

DIRECTIONS.—For Laundry, use two to four tablespoonfuls to a washtub of water. For bathing, use one tablespoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterwards. For stimulating the growth of plants, use a few drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.

Also, SULPHATE OF AMMONIA for chemical purpose, fertilizing, and the preparation of artificial manures. AMMONIACAL PREPARATION, for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing, and PURE LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes.

SEWING MACHINES.

REDUCED PRICE, $35.

HOME and HOME SHUTTLE SEWING MACHINES.

Reduced to Live and Let Live Prices.

These Machines are superior to any and all; nice sewers, straight needle, two threads, shuttle, lock-stitch, the simplest and cheapest, and the lightest running first-class Machines in the market. To see is to convince yourselves.

The Hall Treadle for Sewing Machines,

The most important improvement ever made. It saves labor and preserves health. No more diseases and deaths, side or back aches from using Sewing Machines. No teaching required. A child can run it. Always starts the right way. Never goes backwards and breaks things. Can be stopped instantly. With it on your Machine, you can do double the work you can without it. Fifty stitches can be made with one pressure of one foot. It can be applied to any Sewing Machine. Approved by Massachusetts State Board of Health (see Official Report 1872), Massachusetts Medical Society and Massachusetts Charitable Mechanics' Association. The HALL TREADLE is a part of all HOME MACHINES sold by us.

The Hall Treadle Grinding Machine

Must be seen to be appreciated. For a Farmer or Mechanic to see it, is to buy one. It is an indispensable article in every Farm-house, Shop or Hotel.

The Hall Treadle Jig Saw and Boring Machine

Is an accomplishment in every Workshop. The HALL TREADLE is applicable to all machinery requiring foot-power—Sewing Machines, Grindstones, Jig Saws, Turning Lathes, Jewelers' and Dentists' Lathes, etc. Send for Circulars.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND-POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING and TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

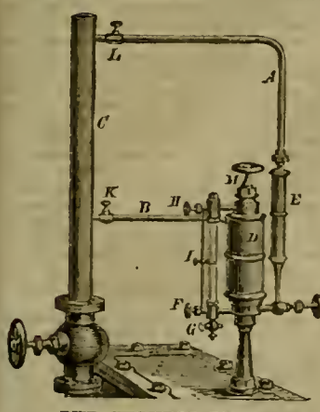
Machinery.

N. Seibert's Eureka Lubricators.



THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stopps; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted it give satisfaction. Patented February 14, 1871. Man ufactured by California Brass Works, 125 First street, S F. 21v23

STEEL SHOES AND DIES

FOR QUARTZ MILLS,

Made by our improved process. After many years of patient research and experiment we have succeeded in producing STEEL SHOES AND DIES for QUARTZ MILLS, which are unequalled for *Strength*, *Durability* and *Economy*.

Die. Shoe.

Will wear three times longer than any iron Shoes.

BUILDERS AND CONTRACTORS

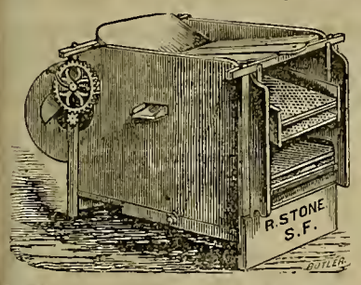
Of Quartz Mills, Pans, Separators, Concentrators, Jigs, Hydraulic Rock Breakers, Furnaces, Engines, Boilers and Shafting, and General Mining Machinery in all its details, and Furnishers of Mining Supplies.

All orders promptly filled.

MOREY & SPERRY,
88 Liberty street, N. Y.

Examination solicited.

THE PATENT
Novelty Mill and Grain Separator



Is one of the greatest improvements of the age for cleaning and separating grain, while it combines all the essential qualities of a first-class Fanning Mill. It also far excels anything that has been invented for the separation of grain. It has been thoroughly tested on all the different kinds of mixed grain. It takes out Mustard, Grass Seeds, Barley and Oats, and makes two distinct qualities of Wheat if desired. For further information, apply to

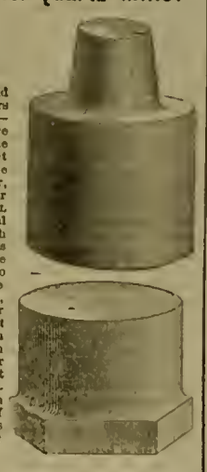
Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.



[PATENTED MAY 26TH, 1874.]

Prices Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

54 BUSHELS OF CORN AN HOUR.
HARRISON'S
LIGHT VERTICAL BURR MILLS
BARBER & BACON, MILLERS AND LUMBER DEALERS, SOUTH VERNON, VT., write July 15th:
"We have been running two of your LIGHT VERTICAL CORN MILLS for the past 6 months with remarkable results, and have ground over 80,000 bushels of corn into No. 1 meal in that time, running the grist-mill nights only, as we run our saw-mill in the day time. We have often ground in the 36-inch Mill (which weighs about 500 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 24,300 lbs., or 434 bushels. To do this we have to run at a speed of 1,300 turns per minute, and use about 20-horse power. You may refer parties to us for further information, and when we have tested your HEAVY VERTICAL MILL, we shall take great pleasure in giving the results."

The Concentrating Works at Falun, Sweden.—Continued.

[Written for the PRESS by CHAS. C. RUECKER.]

Results of Operations in the Year 1870 to 1871.

The following is a summing up of the most interesting dats, conteined in the report of results obtained in the above works in the year 1870 to 1871, the lstest of which I have any relieble acconnt at present.

The works were in operetion 268 days (of twenty-four hours each). The day and night work lested generally from Monday morning to Snadey morniag at fonr o'clock. The rubbish washing works, with its anxiliary appliences, were only in operetion by day, during five and one-half months of the warmer seesons.

There were concentrated, during thie time, 9,713 toae of ore, contaiaig 2.889 per cent., eqnal to 561,219 ponnds of copper.

There were delivered to the emelting works, of piece ore and smell ore, as follows:

	Tons.	Per cent. copper.	Lbs. copper.
Piece ore, first quality	52.74@	18.40=	19,414
Piece ore, second quality	1173.00@	8.48	199,047
Jig ore	578.51@	6.75=	78,081
Small ore from jiggers	72.62@	5.99=	8,709
From percuasion tables	581.52@	7.93=	92,303
From buddles	291.83@	8.93=	52,132
Total	2750.22@	8.17=	449,686

Besides this there were furnished for the lixivieting experiments 335.3 tons fine eand, with 1.75 per cent. of copper, equal to 11,735 pounds, so thet the totel yield of concentretion was therefore 82.22 per cent., and the loss in the work 17.78 per cent.

The average copper value of the concentrated oree, compared with the copper value of the original material, is as 2.84 to 1, and the diminntion of the mass 71.69 per cent.; that is, thirty-five tone are concentrated down to ten tons. A greater enrichment doee not at present take place, because a proportionately large quantity of iron pyritee, conteiaing 1.5 to 2 per cent. of copper, is smelted with the concentrated ores, whereby a better result is ohtained by the use of a poor furnace charge.

The special expenses of concentration, that is, wages, including eapervision, etc., for 100 pounds of copper in eight per cent. of concentrated products, vary, aocording to the percentage of copper in the raw material, between fifty-six cents to $1 25; on the averagé they amonnted to eighty-eight and three-quarter cents, which makes the cost of concentratiag oae ton of ore, as it comes from the mine, thirty-six cents.

From the contiaaance of operations it is confideatly expected that the cost ot concentration, as well as the loss incnrred thereby, will yet he materially decreesed, although the resnits obtained already exceed those previously calculated ou.

In the experimental works the expenses for wagee, includiug supervision, etc., amounted to 5.13 per ceat. (100 pounds) copper contained in the picked ores and concentration products, as sent to the smelting worke—the work being paid for at that time by the day—subsequently it was reduced to 2.28 per cent., hy having the work done in contract, and was then gradually brought down to 1.14 per cent.

Before beginning the erection of the large concentrating works above described, the latter ngure was assumed in the estimatee on the responsihility of the enterprise. The operatives' wagee vary hetween thirteen and fifty cents for a twelve-honr shift.

The loss hy coucentration amounted to 32 3 per cent. in the first trial in the experimental works; in the second trial it was 19 5 per cent., and it varies hetween 25 and 28 per cent. when the worke are in regnlar operation. In the new works the loss is only 17.78 per cent., as stated above. On the other general operating expeases no estimate gen at present he given, the works not haviag heen fally completed at the time, and no reliable accounts of results since then heing at hand.

In the department for the concentration of the ordinary ores twenty-four stamps are still wanting for completion, and besides these an eqnal number of machines and apparatusee, as ahove described, to be set up on the right-haud side of the wing, *B*.

Since the completion of thie divieion will reqnire only ahont one-eighth of the sum which has heen expended for the fitting up of that part of the works at present in operation, and since double the quantity of ore can then be ooncentrated at the eame time, requiring an increase of the number of operatives of only five by day and five hy night, it follows, that on completion of the whole works, the economical results to he ohtained will he much more favorahle than now.

As can he eeen in the plan, the department intended for the concentration of the trikmalm (poor ores), tho wing *C* of the huildiug, is identical in arrangement with the wiug *B*. The stamp hatteries in this division will also contain 56 stamps. When thus fully completed, the works will be ahle to oonceutrate per day 50 to 75 tons of ordiuary malm, with two to threo per cent. copper, and 50 tons poor ores or trikmalm, containing ahout one and one-half per cent. copper. The whole estahlishment will therefore have a working capacity of 100 to 125 toas per day.

The first division of these works will employ 52 workmen by day and 12 by night, and the last mentioned divisiou, 10 by day and an equal numher in the aight, the whole establishment therefore, 84 workmen.

The preceding desoription having heen induced by the desire to show in comparison the manner of work and results as developed by practice here and elsewhere, I wish to revert once more to the cese of the Californie establishment, the experiences in which incited to the comparison.

Although the mine in question is not snfficiently developed to warrent the expeaditnre of a lerge sum of money in the erection of works that could st all be compered with those described, still the fundamental principles in the operations there, end the mechenicel means for oerrying them to practical effect, conld undonhtedly be applied in a limited way to suit the circumstences, and therewith results obteined which would give to the enterprise a firm footing and a more hopeful appearence than it has attained by two yeare of futile efforts to make it pey by the use of rude eppliances, and a yield of ecarcely one-third of the velne which experience elsewhere has proven possible of extraction from an ore of a similer cheraoter.

The main vein of this claim is crossed by several well defined and powerful veins, traceahle for a long distence, and others run perallel to it. A number of these veins contein notehle qnantities of gold beering pyritee. The main vein showed itself quite rich in the croppiags, the rock yieldiag one-third to one-helf of its gold valne to amalgamation of the sulphnrets with which the gold wes origiaally combined. Beyond the limits of surface decomposition, however, very little gold oonld he extracted by amalgamation, although some of the rock was exceedingly rich; reconrse wes therefore teken to concentration and chlorination, as before steted.

The developments on the vein are made by a tunnel ahout 305 feet long, a shaft from the surface to the tunnel about 92 feet deep, and another shaft from the tunnel about 98 feet deeper, at the bottom of which are two short drifts. The vein, contracted in the highest levels near the surface to six to twelve inches, widens rapidly in goiag deeper to eleven to thirteen feet in the tunnel level, then again diminishes. The average width may be set down at ahout fonr feet.

The greater part of the workings were in quartz. The average resnlts of eight to nine months' work show the value to have been quite evenly distributed throughout the parte worked, the average yield of that time approximatiag to that obtained from the concentrating teste spoken of; the values obteined in the latter may therefore be assumed with good reason to tax the value of the vein—by what we know.

As will be remembered, the aversge gold valne of the rock was found by assay to he $30 to $36 per ton. The yield of sulphurets from the rock was ahout one and two-tenths per cent., which contained ahout twenty-three per cent. of gold value. This wonld indicate that the rock contained about five per cent. sulphurets.

This being more than double the average contents of miaeral to be extracted, as found in the ores of Falun, aad the ore being otherwise similar from a concentrating point of view, it is more than probahle that its extraction by the samo method eud means would give a yield at least eqnal to that there obtained—that is, eighty-two per cent.

Grantiug, however, that it would not pay here to carry operations to the same exteat and nicety, we will assume a yield of only two-thirds, or say 50 per cent., and even then the business is worthy of attention. The yield wonld theu he $15 to $18 per ton of ore.

With weges at Falun at fifty cents, as the highest for twelve hours' work, the cost of concentration ie found to be thirty-six cents per ton of ore. Aesuming the average wages here at six timee the above amount, the cost of the concentration, equally multiplied, would be $2.16 per ton; aad the total expense, including mining, etc., not more, probably, than $5 per ton.

The yield being $15 per ton, this would leave a margin of $10 per ton of ore worked, and since 100 tons of ore would yield say five tons concentrated products, containing about fifty per cent. pure sulphurets, these five tons wonld have a net value of $1,000 or $200 per ton.

It would seom that thie onght to suffice to cancel the cost of chlorination; or in the absence of the appliances thereto, defray the expenses of traneportation and eale, and still leave a very acceptable profit. In the latter course ahout $580 would be realized on the 100 tons of ore ahove all expenses.

For the purposes of concentration, the mill on the claim has a crnshing capacity of at least twenty tons per day, end by a judicions method and the aid of other concentrating arrangements the capacity of the works could be raised to thirty tons per day. The cost of these arrangements shonld not exceed $5,000, if designed and built by an experienced person.

This would give a return of ahout $3,000 per month on an investment, in the present standing of the oompany, of about twice that amount, when figured guerdedly on the basis of what others have heen able to do.

The question would naturally be, how long this work could be continued. What prospects in this regard are furnished by a vein, which is well defined on the snrface for about a mile, and whose average yield as far as developed has heen as ahove stated, is left to the speculation of the reader.

Yet such a mine is almost deepaired of by its owners, after an expenditnre of abont $40,000, because the efforts to work it with profit by means of rude and insufficient appliances have failed, and because of a leck of knowledge of and confidence in the meens and methods which elsewhere have proven themselves an unquestioaable success.

The mine above specielly referred to is the Golden Gate, near the town of Sonora, Tuolumne county, Cal., but there are many others in this Stete to which similar remarks wonld apply. With the necessary cepitsl to erect suitable works, many a mine conld be made to yield a reesonable profit, where now the investments of former days are going to waste and irreparable loss.

California Tobacco.

It is only withia the past few years that the cultivetion and manufacture of tobacco has assumed any prominence or heen at all successful in California; but the indnstry hes assnmed such proportions as to wsrrent the belief that in the fature it must be considered a prominent feature in Californie agricultnre and home manufactures. Many of the difficulties experienced have been overcome hy those engaged in the business, and they ere now reaping the reward of persistence and energy and intelligent lahor. It must be confessed, however, thet notwithsteading the excellence of the product, it is much hetter appreciated abroad than at home, sharing in thie respect the disadvantage incident to all new articles of home manufecture. The wines of California, good and pure as they are now conceded to be, had first to he introdnced and appreciated in the Eastern States and elsewhere hefore they came into favor here; and even at this lete day we coasume inferior foreign wines at a high price, while the pure California wines find their best market elsewhere. So, also, with the netive tobacoo. Its excellence is recognized in other States and ooantries, and the consequence is that large exportations are now made, while the home consumption is comparatively small as yet. Our smokers will nee cigars of an inferior character, provided the brand ie foreign aad the price high, in prefereace to cigars made of California grown tobacco, which are sold cheaper, hnt have the stigma of being "home-made."

This prejudice against home-made articles is not peculiar to Californiane, but is, perhaps, more apparent here then elsewhere. It is by no means confined to the case of tobacco, as examples in almost any direction might be cited. Of course in many instances theee prejudices have been gradually overcome by the home-made article driving the foreign competitor out of the market entirely, in which event our people are apt to brag a little of the excellence of the home prodnot. Usually, however, the reputation of the California made article muet he established abroad before it is groperly recognized at home.

Perhaps it may be well to explain a reason for this apparent want of faith in California products by Californians. It is not all prejudice by any means, bnt in many caeee ie a feeling fostered by importers, who desire to keep in the background aay possible opposition. Although this is natural in business competition, it is to he deplored that euch is the case; for the indnstries which would greatly aid California in material progress have, in many instances, been compelled to lie dormant becanse a few people were making money out of au imported article of similar character.

A very striking instaace of this kind is shown in the article of tobacco. The importers of this staple did not wish to see an industry grow up in our midst which would lead to a decrease in their business, and did not desire that a home grown tobacco should be used here at all. Without aay concerted action they individnally held a firm gronnd against the common enemy, and did what they could to discourage its introdnction here. A powerful opposition of this character could wage a euccessful warfare, hy the many means open to it, but in this case the product has forced itself to recognition in spite of all efforts to the contrary. This policy was very shortsighted, as the tobacco might have been procured and the money kept in the country. It has heen the history, however, of very many things here. In the early days everything was imported, and a strong guild of importers grew np, who opposed anything that wonld injure their business. They naturally exercised great power and influence, and do so yet.

As yet thero is hnt one company raising and mannfacturing tobacco on a scale of any magnitude. The American tobacco company and the Pacific tobacco company were organized in 1871 and 1872, and in 1873 they merged into the Consolidated tobacco company, now an organization of considerable importance. Up to that time very little tobecco had been grown here. Some attempts had heen made to make cigars from home raised tobacco, hnt the results were not satisfactory. Smoking tobacco had heen made, however, successfully. In the first year the company grew ahout 30,000 pounds of tobacco, mostly of Havana seed. In 1873 they made np this tobacco into cigars, as a test of the tobacco, and proved at the same time that the claims of the inventor of the process of curing were valid. This ie known as the "Culp procees." They then pnt in 300 acres of tobacco, 100 acres of Havaue seed for cigars, and the rest for filling, emoking, etc. That year they made perhaps 1,000,000 cigars.

In 1874 they had about 500 acree planted, about 150 in Havana seed and the rest in other kinds. This increased the manufacture to 3,000,000 cigers. In 1875 they begen work in eernest, being confident thet time was all they wanted to introduce their products. They had already found favor enough to put up new buildings and enlarge the old one, and et one time dnring the yeer had 785 men at work in the ciger factory at Gilroy alone. All this time the factory for smoking and ohewing tobacco was running elso, 20 men being steadily employed. In this case, however, machinery does awey with hand labor to a great extent.

The compeny prodnced this year abont $600,000 worth of cigers and tobecco. About one-half of this fonnd sale in this market and the rest in Australia and the Eastern States.

The main difficnlty has been, as stated, in first introducing the goods. While meny aoknowledged the excellence of the product it was not for the interest of the trede to enconrage the indnstry. Notwithstending this the company now have a demend for all they can produce. The orders from the East alone are snoh ae to increase the product next year. The excellence and cheapnese of the goods are now both recognized.

The compeny raising end making this tobacco hee a capital stock of $1,000,000, abont 60 per cent. of which hae been peid np. The grounde and factory are et Gilroy, Senta Clara county. The cigar factory ie a large building 275x60, and the other building 130x50. A force of from 750 to 800 men ie worked from April to October, when the force is redneed. The capacity is now abont two million cigars and one million pounds of tobacoo per moath.

We speak of this generally as a home indnstry and will not go into details of manufaotnre or cultivation which would exceed the limits of a newspeper article. If people will nee tobacca they might as well use a home article if it is as good and as cheap, as to use an imported artiole and send the money awey elsewhere. The cigare are well epoken of hy those competent to judge. The company make no pretensions to making a magnificent brand of oigers, which are really made in only one or two distriots ahout Havana, but they claim to mennfacture a good class of cigars and sell them at a rate below the price of cigars not as good, which are called imported. They make some fifty brands of cigare, most of them imitations of well known brands, but they have ten or twelve of their own brands. This tobacco is claimed to conteiu less niootine and to be less injurioue to the smokor than that grown in Havana. The prices are very much below those which are asked for an inferior article of foreign cigars.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., Dec. 13th, 1875.

FOR WEEK ENDING NOVEMBER 30, 1875.*

At a Stated Term of the Circuit Court

of the United States of America of the Ninth Judicial Circuit in and for the District of California, held at the court room in the city and county of San Francisco, on Thursday, the 30th day of September, in the year of our Lord one thousand eight hundred and seventy-five. Present—The Honorable Lorenzo Sawyer, Judge.

Nicholas Selbert, complainant, vs. Wm. T. Garratt, defendant—In equity.

DECREE.

This cause came in to be heard at the February Term, A. D. 1875, of this Court and was argued by counsel and thereupon upon consideration thereof, it was ordered, adjudged and decreed, as follows, viz: That defendant, William T. Garratt, was not the first or original inventor, or discoverer of the improvement or discovery claimed by him, in and by those certain reissued letters patent of the United States, number five thousand three hundred and twenty-eight (No. 5328), for an alleged new and useful improvement in lubricators, issued to said defendant, William T. Garratt, on the 18th day of March, A. D. 1873, and is not entitled to a petent therefor, and that said reissued letters patent, number five thousand three hundred and twenty-eight (No. 5328) are declared void and the same are hereby vacated and set aside by reason of their interference with those certain letters patent of the United States, number one hundred and eleven thousand eight hundred and eighty-one (No. 111,881) for a new and useful improvement in lubricators, issued to complainant, Nicholas Selbert, on the fourteenth (14th) day of February, A. D. 1871.

It was also further ordered, adjudged and decreed that complainant do have and recover of and from defendant his costs and expenses to be taxed herein.

(Signed) LORENZO SAWYER,
Circuit Judge.

The above decree has reference to "Selbert's Eureka Lubricator" for oiling the valves and cylinders of steam engines.

It has a glass gange and condensing pipe, or reservoir, with a regulating feed valve, and works as follows: As the water of condensation is admitted, under the oil, just so fast the oil passes ont at the top through a pipe into the steam pipe to oil the valves and cylinder.

Parties who infringe or purchase the infringed lubricators, will be held strictly responsible.

N. SEIBERT, Patentee,
125 First Street, S. F.

OF INTEREST TO

MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially *machinery for mechanical ore concentration*, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR APPLICATION—requiring no thinner or dryer, and will not epoil by standing any length of time.

It is Cheaper, more durable, more Elastic, and produces a more Beautiful Finish than the best of any other Paint.

It will not Fade, Chalk, Crack, or Peel off, and will last twice as long as any other Paint.

In ordering White, state whether for Outside or Inside use, as we manufacture an Inside White (Flat) for inside use, which will not turn yellow, and produces a finish superior to any other White known.

Put up in ¼, ½, 1, 2 and 5 gallon packages, and in Barrels. Sold by the Gallon.

For further information send for Sample Card and Price List, or apply to the office.

Important in regard to Pumps.

Aurora, Nevada, November 10, 1875.

H. P. Gregory & Co., San Francisco.

Gentlemen: I am exceedingly well pleased with the "SPECIAL PATTERN BLAKE MINING PUMP" and its workings; especially so with the "MORTON EJECTOR CONDENSER." Have both in position on 400 foot level. The condenser is doing all that is recommended, and is saving from one and one-half (1 1-2) to one and three-quarters (1 3-4) cords of wood per day, I consider it a very useful improvement.

Yours Respectfully,

Warren Rose, Supt. Juniata Cons. S. M. Co.

We are prepared to put in the "BLAKE IMPROVED STEAM PUMP" in connection with the "MORTON EJECTOR CONDENSER" and fully guarantee a saving of from thirty to forty per cent. over any other direct acting Steam Pump in use.

H. P. GREGORY & CO.,

SAN FRANCISCO, SATURDAY, DECEMBER 18, 1875.

VOLUME XXXI Number 25.

Formation of Geyser Mounds.

In describing the extinct geysers in Montana, Professor Hayden speaks of a trip to the Clark Fork mines, on the road to which he passed the Soda Butte, a prominent extinct geyser. Soda Butte is a large mound, the materials of which are mostly calcareous, and show clearly that these limestones run under the valley, and that the waters of the geysers rose to the surface through them, dissolving more or less lime in the passage upward. The accompanying cut represents an ideal section of Soda Butte, showing the pipe or orifice and the manner of the deposition of the layers, or growth of the mound. As a curious geological formation the engraving is interesting. The other engraving represents a view of extinct oblong geysers. These are from 50 to 150 yards in length, from 6 to 10 feet high, and from 10 to 15 feet broad at the base. There is in all cases a fissure from one end of the summit to the other, usually from 6 to 10 inches wide, from which steam sometimes issues in considerable quantities. The inner portion of the shell, as far down as can be seen, is lined with a hard, white enamel like porcelain; in some places beautiful crystals of sulphur have been precipitated by the steam. These have been built up by a kind of oblong fissure spring, in the same way that the cones have been constructed. The water was continually spouting up, depositing sediment around the edge of the fissure, until the force was exhausted and then the calcareous basin was rounded up, something like a thatched roof, by overlapping layers. The view given shows one of these extinct oblong geysers, some of which were broken down, so as to leave a mere shell or cavity, which is now the abode of wild animals. When Professor Hayden and his party entered one of them it was filled with bones and sticks, which had been carried in by wild beasts. Some of these mounds have been worn away, so that sections are exposed, showing the great number and thickness of the overlapping layers of sediment.

At the Kossuth mine, on the Comstock, a novel method for furnishing air has been adopted at the 350-ft station. An air machine has been attached to the pump rod, saving the necessity of extra machinery and power for driving it, and which furnishes a bountiful supply of air for the 350-ft level. Several important improvements to the machinery have just been completed. A new 54-inch boiler has just been put in, new reels and brakes added, new wire cables. 3⅛ inches wide and 1¼ inches thick, put on, and a new steam pump erected for supplying the boilers with water, the old steam engine being kept ready for use in case of fire.

The Belcher mine's gross yield for the month of November amounted to $440,000, netting a clear profit over and above all expenses of $210,000—a pretty good showing for the Belcher mine, and proving conclusively that the mine really occupies a higher and more favorable rank on the list of Comstock mines, than the figures at which the stock is selling seems to warrant, as compared with others.

The Best & Belcher company proposes erecting heavy machinery shortly to work deeper and open the mine to a much lower level, at the same time extracting the good ore at the present level to pay expenses.

The Globe Consolidated mine, on the Comstock, is to have pumping works of the best and most powerful description. The plans are now being drawn.

On the Utah mine a large force of workmen are at present employed on the new hoisting works, which are being pressed to completion with all the energy possible.

The Original Gold Hill company have leased the Woodville mill, and the Hope mill is now running on ore from the mine.

T. J. McClellan has been appointed Superintendent of the Justice mine, in place of John Dunn, resigned.

The White Pine Bonanza.

It was only a week or so since that we gave an account of the closing down of several mines at White Pine, Nevada, and stated that the prospects of the district were very gloomy. On the heels of this announcement, however, comes the pleasanter one that White Pine has struck her bonanza, and that at a sufficient depth to assure a permanency to the different deposits. The impression has always prevailed, after the great and exciting rush to the district, that the mines were composed of surface deposits that did not "go down." Others, however, believed that the big ore channel run through Treasure hill, and was not only on the top. The late discovery in a measure settles the question, and the English company deserve great credit for their persistency in solving it.

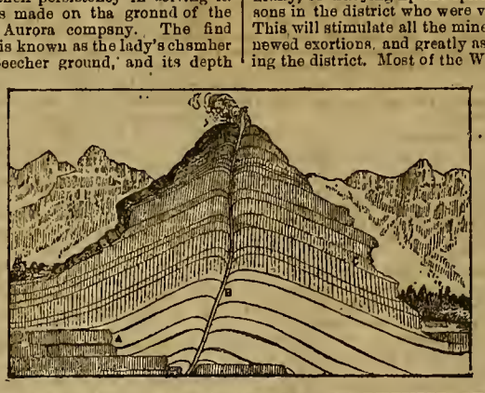
The strike was made on the ground of the Eberhardt and Aurora company. The find lies under what is known as the lady's chamber of the Ward Beecher ground, and its depth connect with that. The Eberhardt and Aurora company are sinking a working shaft, which is now down to a depth of 600 feet, and the indications are very flattering for striking a body of ore almost any day. When this occurs, then the problem of the "ore not going down," will be solved, and every company owning mines on the hill will be ready and willing to go down. It is stated that several San Francisco companies are only waiting for the English company to do the prospecting, when they hope to reap the benefits of it.

In addition to this strike the Elko mine in the same district has just struck it richer than ever. The body of ore they are now working

EXTINCT OBLONG GEYSERS.

is worth from $200 to $300 per ton, and there is a large amount of it in sight. It is thought further developments will expose a very large deposit.

The new discoveries have had the effect, naturally, of buoying up the spirits of many persons in the district who were very despondent. This will stimulate all the mine owners to renewed exertions, and greatly assist in developing the district. Most of the White Pines now



CARBONIFEROUS LIMESTONE SECTION OF EXTINCT GEYSER.

from the surface is 560 feet. We have no information as to the extent or richness of the body, but the supposition is that an immense bonanza of high grade ore has been uncovered. At latest accounts the bonanza was still widening out and improving greatly. It is believed to be by far the largest body of ore ever discovered in White Pine county, and what is better still, it is of exceeding high grade. Taken right through it is believed that the whole deposit will average about $300 per ton. Considering the great depth of this find and its general trend into the mountains, there can hardly be a question that it is the most important development that has been made in Eastern Nevada for a long time.

The new discovery is in virgin ground and will require some time to determine its extent. The White Pine *News* states that there is one thing known positively about it, however, that directly under the new body of ore, at a depth of 105 feet, there was ore in the old workings, and it is probable that this new discovery will look upon the permanency of the district as an assured fact. Those who have had faith, and have seen their predictions verified, ought now to reap their reward. The Eberhardt and Aurora company intend doing a great amount of work this winter, both in drifting and sinking. The old workings of this company are very extensive, some of which have not been touched for years, and by further developments the chances are now very favorable for discovering other chambers of ore that now lie hidden. We are glad to see, after all their bad luck, that the company will probably be rewarded. We sincerely hope that all that is anticipated will be realized, as these discoveries go far toward restoring confidence in much abused White Pine.

Preparations are being made on the Lady Bryan mine to put in pumping machinery of the largest and best character, which, when completed, will place the Lady Bryan on a footing with the first-class mines of the Comstock.

Legislative.

The current proceedings of both Congress and the State Legislature have been pretty fully reported in the daily press, and much that is done is of little general interest. Our State Legislature has done little as yet except stopping any chance for change in text books in the public schools. Now that the inaugural ball is over, however, we may expect the members to knuckle down to work. We note the following matters of general interest: McGarvey's bill relative to the collection of taxes provides that taxes shall become delinquent on the first Monday in July, instead of January, and that, unless paid prior thereto, ten per cent. will be added, instead of five. Any person may pay half his tax prior to the first Monday in January; in all cases where this is not done, ten per cent. on one-half of the whole amount shall be collected for the use of the county. The delinquent list must be furnished on or before the first Monday in August.

A bill has been introduced by Senator Haymond to provide for the permanent improvement of the State capitol grounds.

Assemblyman McCarthy is getting up an apprentice law.

The "No Fence" law will probably crop out this session.

The sale of mineral lands was the subject of much discussion two years ago, and now it is to come up again. Senate bill No. 40 is to amend the act approved March, 1874, and provides that any person in actual possession of any mineral land belonging to the State, or owning a mining claim thereon at the time of the United States survey or the passage of this act, shall be considered a preferred purchaser thereof to the extent of his or her mining claim, provided that within ten months from the passage of this act a copy of the plat is already filed, or if not within six months of the filing of the plat in the United States land office, he makes demand and tenders the purchase money. There are other provisions where a mining claim covers only a portion of a section.

Some half dozen bills will be introduced relative to the completion of the City hall in this city.

An act for the suppression of quackery has been introduced.

Senator Rosch has introduced a bill providing that wife-beaters be punished by the lash.

Mr. Clark's bill for the protection of lumber manufacturers has a special interest for the counties of Del Norte, Mendocino and Humboldt. It provides that the driving into or placing within any tree, or log, shingle, bolt or other wood intended by the owner to be manufactured into lumber, any material likely to injure saws, shall be considered a felony, and shall be punished as such; and that the destruction of booms shall also be considered a felony.

The committee on mines is composed of Birney, Blue, Griswold, Dunlap and Critchen.

The committee on agriculture, mining and mechanics' arts college is composed of Carson, Dixon, Sullivan, Quigley, Reddick, Raisch and Jones.

McCoppin has introduced a bill providing for an amendment to the constitution, restricting the power of all counties, cities and incorporated towns in the State to create any debt or liability, for any purpose whatsoever, exceeding five per cent. of the property therein from which revenue is actually derivable; and all existing debts and liabilities of said counties, cities and towns shall be included in the said five per cent. limitation.

A State inspector of boilers is spoken of.

The San Francisco water supply is taken care of in Senator Roach's bill.

From the Victoria *Colonist* of November 28th: Within a very short time past it has come out that a very large quantity of bogus metal was introduced into the gold dust during Cassiar, by some knave from south of the line. The mixing was done at Cassiar. The bogus stuff is known as spelter. It is not calculated to deceive an experienced person, except in the hurry and hustle of a mining camp, where an examination is not always possible.

McCloud River Salmon Fishery.

Work Done by U. S. Fish Commission Under Superintendence of Deputy Commissioner L. Stone.

Part First—Historical.

Far off as any such result may seem now, it is nevertheless true, that were the salmon rivers of this coast left to take care of themselves they would in a few years be despoiled of their inhabitants and therewith lose their chief value. Such has been the result in the Eastern States, where salmon once swarmed in the streams, and it is only after long years of almost utter barrenness that they are now being fitted for the reception of and restocked with the fish that once made them their homes.

This work of preparation is one of great trouble and expense. Fish-ways have to be built over dams and falls; manufacturers have to be compelled to keep the injurious drainage from their factories from polluting the streams, and many a suit has to be instituted and carried on to bring about all the results necessary to fit the water for the reception of the fish. When their home is ready the fish have to be put into and protected for a number of years, to be allowed to breed and restock the waters.

The stocking of rivers by catching and transporting the fish alive is a slow and tedious process and one unproductive of quick results, and in its place—quicker, safer and cheaper—has grown up the new art of fish hatching. The art, as it is now practiced, has in truth grown from seeds sown hardly more than ten years ago, when the attention of legislators was most forcibly called to the condition of the fish rivers of the East.

Although the process of the artificial impregnation of fish eggs was discovered in 1763 by Jacobi, a German, yet it had undergone no change of any great note till about twelve years ago, when the thoughts of many intelligent Americans were turned to it. Then it was taken up in good earnest, and like that of many other Old World inventions, its history in America is but a record of rapid and continued improvement, and here in California it has made, within the last four years, some of its most rapid advances, and has adapted itself to the scale of grandeur characteristic of all things in the land.

The Rise of Fish Culture.

About 1866 almost all the Eastern States passed laws providing for the protection and propagation of fish within their limits, and appointed commissioners to take charge of the work. Very good work has been done by these commissioners, and the Western and far Western States have taken up the work, and many are now reaping the fruit of their wisdom. In our own State much good has been done by the State Commissioners and the Acclimatization society; white-fish have been put into Clear lake, shad into the Sacramento, and salmon into Lake Merced, the Truckee, the McCloud, etc., and the work of protection carried on as thoroughly as possible.

In 1871 a United States Fish Commission was organized, with Prof. Spencer F. Baird as chief commissioner, and a fishery was established, in conjunction with several State Commissions, on the Penobscot river in Maine, under the superintendence of Mr. C. G. Atkins, where salmon were caught and their eggs taken and prepared for shipment. This was, till the establishment of the McCloud river fishery, the largest salmon fishery in the world, and great good has been done by it.

There are there, however, several disadvantages that are not experienced on the McCloud. As the fishing grounds on the Penobscot are all owned by private parties, the Government has no right to use them for procuring salmon eggs; all fish, therefore, have to be bought from owners of the grounds at $3 apiece. Then, as there are laws prohibiting the capture of salmon for some time before the spawning season, all the fish have to be caught five months before they are ripe, transported to a pond a mile from the river and there kept till ready to spawn. The consequence of all this handling and interference with nature is that the eggs are soft shelled—the shell of a salmon egg is a tough membrane—and consequently very difficult to handle. Notwithstanding these disadvantages, the Maine fishery has done an immense amount of good work, and millions of young fish from it have been put into the Connecticut and other Eastern rivers.

Numbers of private persons have also gone into fish culture with great success, and to many of them the eggs from California are sent to be hatched out for the different States, by whom the cost of the packing, transportation and hatching is paid.

Successful as were the results obtained at the Maine fishery, yet the number of eggs was found so inadequate to the demand that it became necessary to provide some other source of supply, and California being well known as having rivers well filled with salmon, was selected as the new field of operations.

The McCloud Fishery, 1872.

In the summer of 1872, Mr. Livingston Stone, Deputy Fish Commissioner, came to California, in compliance with orders from Professor Baird, to inspect the salmon rivers of the State, to find a site for a salmon fishery, and to commence work immediately if possible. Strange as it may seem, he could find no one in San Francisco who could answer his inquiries as to the time and place of the spawning of the California salmon. It was generally known that they were most abundant in the Sacramento, and that they ascended it in the fall; but no one to whom he applied had ever seen them on their spawning beds. After many days of fruitless inquiry, Mr. Stone learned from Mr. Montague, Chief Engineer of the Central Pacific railroad, that he had seen salmon in great numbers in the McCloud river, and he pointed out on a map a spot that he thought would do for the site of a fishery. Thither Mr. Stone and his assistant, Mr. J. G. Woodbury, proceeded, arriving September 1st, 1872.

They found the salmon abundant, but on examination it became apparent that almost all had spawned, and that the number of eggs would necessarily be but small that year. They established themselves at a stage station, about three-quarters of a mile from the river, by a small brook, and in three days, by hard labor, built a house and troughs, and were ready to set to work to collect eggs. Here came trouble for them. They experienced great difficulty in obtaining fish. They tried many nets, but all failed, except the seine, and theirs was not suited to the rapid current and did not work well, and most of their fish were got by watching the Indians, and as soon as any one speared one to rush and take it from him and take the eggs. But the fall run was nearly over, and twelve ripe females, yielding 50,000 eggs, were all that could be obtained.

The now old style of troughs, with charcoal and gravel bottom, were then in use, and into such the eggs were put, out in the sun, with the thermometer sometimes at 110, with only a board to cover them, for there was no time to build a roof. There many died, but the remainder prospered till the water, stirred by animals, began to deposit on them a coating of hard mud that could not be washed off. No remedy could be found for this, and it went on till not an egg was visible and all were in imminent danger of suffocation. All hope was given up at one time, but Mr. Woodbury decided to run the risk of killing them immediately in washing off the dirt. Taking the eggs in a bucket, he put in a handful of sand and held them under a stream of water, that stirred them gently till all were scoured clean. Of the eggs thus treated, only a small percentage died from the operation, and most of these were unimpregnated. Of the original 50,000, 20,000 died from heat and other causes, and 30,000 were shipped East, hatched and put into East, ern water, and last year the grilse were taken being three times as large as Eastern grilse of the same age.

These eggs were packed in wooden boxes, instead of tin or glass jars; this was then necessary from the length of the journey, and more so since from the immense number of eggs and the rapidity with which it is necessary to pack them. The results, too, are more favorable with wooden than with tin boxes.

Season of 1873.

After a season's experience, Mr. Stone decided, as there was no clear spring water available, to move his whole establishment down to the river, near the seining ground, and, contrary to all precedent, to use the water from the river in the troughs. This was done, a dwelling house erected, troughs put up under a tent sixty feet by thirty feet, and an undershot wheel, twelve feet diameter and eleven feet shaft, was made and set up to raise water, a fish barrier put in the river to stop the salmon, and by August 19th all was in readiness to begin the work.

The McCloud.

The McCloud river, on which the fishery is situated, is a tributary of the Pit or Upper Sacramento. It rises in two forks in the foothills of Shasta butte, and nearly half its volume comes from a spring that rises in the bed of the stream, coming underground from the melting snows of Shasta. This is very cold, and gives the river a low temperature that it never loses, running an icy flood to its mouth. The temperature of the water in mid-summer is never above 63°, though the air is sometimes 130°, and at night it generally falls to 40°; in the winter it is still lower, but it never freezes, on account of its rapidity. The descent of the river is very swift—about forty feet to the mile—and every few hundred yards there is a rapid, where the water boils and surges over the rocks with tremendous force. At the fishery the stream is from thirty to fifty yards wide, with an average depth of seven feet. About sixty miles from its mouth the river passes over a perpendicular fall about seventy feet high, said to be one of the most beautiful in the State. The edge of the fall is perfectly even, and the water passes over it in one unbroken mass, twenty or thirty yards wide.

The valley of the McCloud is shut in by high hills, or, more properly, mountains—as some of them rise 4,000 feet high—that rise but a short distance from it, leaving but little low land that is of any value; this is covered with oak, pine, ash and underwood, and was once thickly inhabited by a tribe of superior Indians, but they are nearly extinct, and none are to be found more than twelve miles from the mouth. The banks of the river are fringed with a water-plant, bearing large green leaves. This lives naturally in higher altitudes, but has become naturalized to the McCloud valley from the coldness of the stream.

The river is one of the chief spawning grounds of the Sacramento salmon, and so long as its waters are kept clear and unobstructed there can be little fear of the extinction of this fish. To this end all miners must be kept from it, and the wisest use that the Government can make of the whole valley is to appropriate it for an Indian reservation.

Inventions and Improvements.

In 1872, Mr. Woodbury, the foreman, had experienced great inconvenience from the cracking of the charred bottom and sides of the old troughs, and experimented with various substances in the endeavor to find something that could be used in place of the charring to prevent the growth of fungus, that would have no harmful effect on the eggs. All others seeming useless and thinking of the insolubility of asphaltum, he experimented with it with favorable results, and the second year part of the troughs were coated with it. No harm resulted from it, and ever since it has been used exclusively with the greatest success. It gives a hard, glossy coating to the wood and can be very easily cleaned of any dirt deposited on it and renders the trough perfectly water-tight.

In 1873 some of the then new trays of wire gauze were used to hold the eggs and the accompanying double dams to secure complete circulation of water. These were found to be an improvement on the gravel, but had to be handled with care, as the eggs rolled off from them with perfect ease. From this circumstance Mr. Woodbury decided to put sides to these trays, and contrary to the directions of fish culturists, to put in several layers of eggs. This was done in 1874 with part of the trays, all charcoal and gravel being done away with, and 25,000 eggs were placed in a tray two feet by one foot and six inches deep; the double dams being also used.

This invention was a great success; the eggs were more healthy and could be handled with great ease and rapidity; by moving them gently up and down all dirt could be freed from them; and it is principally by the use of them that this fishery has been able to send away such large numbers of eggs.

Season of 1875.

The seasons of 1873 and 1874 were very successful in their results, and the latter in particular noteworthy for the large number of eggs taken, but the season of 1875 has far surpassed any preceding in all respects. Not only has the number of eggs been larger, but they have been much healthier, and although the water brought down more sediment—for there was no freshet last winter to clear the river bottom of last year's deposit—the eggs at packing were noticeably clean, having no fungus attached to them, and as bright as when first taken.

Whether it was the natural result of experience or some favorable condition of the work is not evident; but this year it was found that two men, with Indian assistants, could spawn twice as many fish as in any previous year, and that the eggs taken thus rapidly were in no wise inferior, but rather superior to those of former years. The greatest number taken in one day was 896,500, and more fish could have been spawned but could not be obtained. The largest number taken from one female was 9,000.

The Result.

The whole number taken in 1875 was 7,822,900; of these about four per cent., 314,900, died and were picked out; 5,658,000 were shipped East, and 1,850,000 left for California. Of those left for California 240,000 were sent to the Truckee river and hatched, and as many to Kern river, but the latter were killed by the alkali water. 1,370,000 were hatched on and put into the McCloud. 50,000 eggs were sent to New Zealand by the Acclimatization society, and as every effort has failed to get them from England, if this succeeds—as it can be made to with sufficient care—there will be quite a demand for eggs from the countries beyond the equator. Those sent East went to various States as follows: Utah, 160,000; Colorado, 240,000; Iowa, 300,000; Minnesota, 400,000; Illinois, 80,000; Wisconsin, 40,000; New York, 80,000; Pennsylvania, 480,000; Michigan, 800,000; New Jersey, 320,000; Maryland, 560,000; Virginia, 320,000; Connecticut, 480,000; Rhode Island, 200 000; Massachusetts, 80,000; the Canadian Government, 80,000; N. W. Clarke, for U. S. Fish Commission, 988,000. Those first sent arrived in good condition, the others have not been heard from. The following is a comparative table of the four years' work. Twice as many males were taken as females.

	1872.	1873.	1874.	1875.	Total.
Females.	12	5,00	1,350	1,792	3,654
Eggs Hatched.	50,000	2,000,000	5,675,000	7,822,900	15,547,900
Eggs Shipped.	30,000	1,500,000	4,100,000	5,658,000	11,488,000
Eggs Hat'd at Fishery.	.....	.....	850,000	1,370,000	2,220,000

Future Work.

It is now evident that the fishery, as now arranged, has nearly reached its maximum of productiveness, and that that can only be increased by the establisment of new seining grounds, above and below the present one, and the building of a permanent hatching house. Both of these are of easy performance and will, in all probability, be carried out next year. The hatching tent, as now situated, is in the bed of the river in winter time; but about a hundred yards up stream, close to the hill, a permanent hatching house can be built, that will be out of the reach of the floods, and opposite is a rapid where a wheel can be placed to raise water to it.

As there is plenty of timber of all kinds on the hills around, and numbers of Indians ready to work for moderate wages, one white man can, during this winter, get out all timbers necessary for the frame, and next summer all the hands can be employed in putting up this building, instead of the tent that has to be taken down every year. Perhaps it may seem strange to speak of taking hands from raising a tent to a building; but, be it known that to put up and *take down* every year the tent, boxes and flumes, costs between one and two thousand dollars. Thus the building expenses for not more than two years would easily pay for any hatching house that is needed on the McCloud. All the sawn lumber needed will be shakes for roofing and sugar pine boards for boxes, flumes, etc., and if this is ordered and sawed a month before it is wanted, so as to have time to season, the expense of hauling will be but small.

After the troughs have been once erected there would be no need of tearing them down, which cracks and injures them; but they could remain for years with no repairs but a coat of asphaltum annually. If this house were erected the cost of the eggs would be very small and the usefulness of the fishery greatly increased.

As one of the men is to remain at the fishery all winter, there is all probability that this work will be done next year.

Future Hatching on the McCloud

As the fish hatched from the eggs taken here will, in due time, grow up and spawn in Eastern rivers, and their eggs can then be taken and hatched there, the demand on California will, before long, be over.

As the State Commissioners have every year numbers of eggs hatched on the McCloud, as soon as this establishment is suspended, there will be need for them to have a fishery of their own on the McCloud; and Mr. Woodbury, the superintendent of their works, has found a place that seems to possess all the advantages that can possibly be imagined for hatching salmon, and collecting the eggs of the "Dolly Varden" trout.

The Dolly Varden or Wye-dar-d'ee-kit

Is a trout indigenous to the McCloud and Little Sacramento. There are reports of its having been found in some other streams, but they are not well authenticated. It is peculiar in shape, having a large head and mouth, and increases in size regularly from the tail to the head. It is bright yellow in color and has along its back rows of large dark spots, and on its sides spangles of red, silver and gold; presenting altogether a very beautiful appearance. Its tail and fins are of the most beautiful construction, giving it great power and rapidity in the water. They are frequently caught of eight and ten pounds weight, and there are rumors of larger ones, but only rumors. It is comparatively rare, being usually found near the head waters, and only in cool water. It is, altogether, perhaps the finest trout in the world, and if it were once known there would be an increasing demand for it. It is the intention of the commissioners to obtain eggs, if possible, and introduce them into other streams.

The Place for a Fishery.

But the work of obtaining these eggs from the river will be attended with great difficulty, as they probably spawn in the winter; when the river is high; but there is a place about eight miles above the fishery, where a brook comes down from the mountains. On this brook, near where it empties into the river, lives an old Californian, Mr. J. B. Campbell, who has there a garden and orchard watered by the water from the brook. This is a fine, cold stream at all seasons, and the only one on the river available for hatching purposes, as above it all is an uninhabited wilderness for sixty miles.

In this stream, every winter, spawn the Dolly Varden and other trout, and their young are frequently seen in the irrigating ditch in summer. Here then is the place, and the only place on the McCloud, to establish a permanent State hatching house and fishery for front and salmon; and the conformation of the brook bed is such that a large fish pond for breeding trout could be built there at a trifling expense.

Mr. Campbell favors the establishment of a fishery there; and as he has been, during this whole season, assisting at the fishery, understands the business thoroughly and could thus render valuable assistance. The only trouble in having a fishery there would be the necessity of widening the present trail into a road, as it is eight miles from the stage road; but as this runs along the valley bottom, it can be done at no great expense. It will be done sometime, and the sooner the better.

The keel of an immense double turreted monitor is being laid at Roach's ship yard, Chester. The vessel, when completed, will be a monster, and will no doubt be a valuable addition to the United States navy.

All the forms of law have been complied with in the removal of the principal office of the Cherokee gravel mining company, from the town of San Juan, Nevada county, to San Francisco.

The Northern Belle mine shipped $7,315 on the 3rd inst.

MECHANICAL PROGRESS.

Utilizing Old Railroad Iron.

Tha Russians seem to be making rapid progress iu almost every department of manufacture. The labor reports for that country report the following in the matter of utilizing worn out rails:

Conversion of Old Rails Into Steel.

The Russlao railway company have been experimenting in their works at St. Petersburg, on the conversion of old rails into steel by the ferro-manganese process. Rails taken out of use from the Russian railways were subjected to treatment in a Siemens-Martin furnace, in the following order: (1) rails manufactured in the company's works from old rails made from puddled iron got from Finland pig; (2) ditto, with steel heads; (3) old rails made at Ponti-loff, similar to the foregoing; (4) old rails of English make, marked Dowlais and Weardale; (5) Bessemer rails of English make (Cammel, Brown, Bailey and Dixon). In the first bath a Swedish pig, almost white, and very impure, was used. The different samples contained the following proportions of phosphor: Old rails, 2.62 to 4.52 thousandths; old steel rails, 0.82 to 1.65; Swedish pig, 2.95. The ferro-manganese employed contained from 42 to 44 per cent. of manganese. Nine runnings were made with different mixtures; the respective quantities of the substances varied from 17 to 25 per cent. for the pig iron; 80 to 72 per cent. for the old rails; 3 per cent. of ferro-manganese. The contents in phosphorus varied, in the products obtained, from 2.30 to 3.35 thousandths for rails manufactured from old iron rails, and from 0.48 to 1.50 thousandths for rails made from old steel rails. The rails of phosphoric steel thus obtained have resisted successfully the tests of both crushing and tensile strains as prescribed by the directors of the Russian railway company.

A Six Cylinder Engine.

A six cylinder stationary engine has been brought out, and under a fair trial has shown good results. The engine consists of a bed plate supporting a circular iron casing, in which are placed six small cylinders in a ring, with their axes parallel to the main shaft that passes between them all. Each cylinder is single acting, and has a hollow piston, having a smoothly rounded end, in place of a piston rod. At the rear of the casing is a disk, balanced in the center, and supported by a joint that allows it to turn freely in any way. To this is fastened a short arm that is geared to the main shaft. The operation of this engine is quite simple. On admitting steam one of the cylinders pushes its piston back against the disk, and makes a partial revolution on its pivot, dragging the shaft round with it. Before this piston advances far the port of the next cylinder opens and begins its work. The next cylinder comes into play by the time the first has nearly completed its stroke, and this one then exhausts and its piston is driven back by the motion of the disk. In this manner each piston makes its stroke in turn, and its piston is returned by the disk for the next stroke. As each overlaps the other the motion is continuous, and in making one revolution of the shaft and disk each cylinder makes two strokes. Three are at work and three are going out at the same time. Each piston presses the disk in turn as it rolls under them, and each in turn is pushed back. The exhaust steam makes some resistance, so that the disk and returning pistons are kept in contact, and there is no shock or jar. A four horse power engine of this pattern measures outside only 17x17 inches, and gives a combined piston area of 33 square inches. All the parts are easily examined and the engine is said to run at a high rate of speed and with a good economy of steam.—*Scribner.*

A New Pin is exhibited, which promises to become quite popular for many purposes, on account of the impossibility of its working out of the fabric in which it is placed. It is made of a piece of ordinary wire sharpened at both ends. One extremity is then turned down and wound spirally for a couple of turns about the shank. When the pin is inserted, a slight twist given to the bent end causes the sharp point on the spiral to catch and enter in the cloth. The inventor has not only devised the pin, but some very ingenious machinery for its manufacture. One apparatus cuts off the wire, sharpens the ends, and throws the piece into a hopper, whence it passes into another machine which produces the spiral. The rate of production of the pins is about 200 per minute. Mr. R. W. Huston, of Brooklyn, New York, is the inventor.

Mineral Wool.—This new substance, made from furnace slag, was placed on exhibition at the late fair of the American Institute, N. Y. The material weighs about thirty pounds per cubic foot, and is sold at two cents per pound. It costs about five cents per square foot of surface, one inch in thickness. It closely resembles genuine wool, but is of much shorter fiber, and is somewhat gritty. From a report of tests made by a committee of the Franklin Institute, we learn that, when used as felting, the mineral wool retains heat somewhat more than one-tenth longer than common felting. The material is entirely indifferent to dampness and fire, and does not decay.

The Oil Engine.

In regard to this engine, already noticed in these columns, the New York *Evening Post* of recent date, remarks as follows: An engine has lately been devised, and is now in successful operation, in which oil and common air supply the place of steam, and which can be started by applying a match as easy as a gas burner is lighted. The system is an improvement on that of the Brayton gas engine, the principle being substantially the same in both machines, while there is some necessary differences of construction. The cost of running the oil engine is much less than the expense of the other, which was invented about two years ago.

The oil engine, which is also the invention of Mr. Brayton, resembles a steam engine in many respects, but is, of course, without a boiler. A can is attached, containing the oil, which is introduced by a pump into the cylinder of the engine. The oil enters a burner in the cylinder in the form of a spray. An air pump forces air into a reservoir at the bottom of the engine, from which, through an induction pipe, it passes into the cylinder. There it comes into contact with the oil in the burner and is instantly carbonized. The combustion, which is occasioned by simply lighting a match, results in an expansion of the air at the rate of six to one, and thereby the power is produced. A little jet of air constantly passes around the induction valve opening into the burner, and keeps the flame alive when the valve is closed.

The required pressure is obtained within a minute after starting, and is regulated as in an ordinary engine. The oil engine is therefore always ready for use, without causing any expense to the owner when not in actual operation. It has no highly heated surfaces, requires no manual work in its setting, and is free from sparks, smoke and cinders.

The power of the engine ranges from half a horse power to thirty horse power, but it is hoped to build some still more powerful.

Rolling Rail Blooms.—Another new thing in the iron trade of that country is reported by an English correspondent of the *American Manufacturer*, as follows: "Let me announce as a new thing in the iron trade of Russia, that in the part of the kingdom of which I speak blooms to make tops or tops and bottoms of rails in Russia, (according to whether the rails are double or single headed) are being largely rolled. The Russian engineers, no longer extravagant, certainly as to rail making, are importing half manufactured iron of this class and will thereby economize their own old rails, which will form the centre of the piles out of which the new rails will be rolled. Note the economy of this. Instead of sending their old rails to England as scrap, they keep them there and use them up with these blooms, which they buy from us rolled to the sizes and cut to the lengths adaptable to the section of rails to be rolled in Russia. So long as old rails can be made to last out, this plan will keep down the import of rails into Russia very materially, inasmuch as an order for perhaps 600 tons of bloome will be made to suffice for what otherwise would have been an order for 2,000 tons of completed rails.

Long Rails.—During the recent celebration of Darlington of the fiftieth anniversary of the opening of the first passenger railway, the Britannia iron works company, at their works at the neighboring town of Middlesborough, rolled for the inspection of visitors some rails of unprecedented length, and it is proposed to place one of them, 130 feet long, near the first locomotive engine, opposite the Darlington station, as a memorial of the jubilee. During the same week this company rolled in one mill, 1,350 tons of rails 40 lbs. per yard, a quantity which it is believed has never been even approached in any other mill in the same space of time. The rails were for the New Zealand Government railways.

The Consumption of Iron—or more properly the utilization of iron in its raw and unworked state, for iron is never consumed—in the United States, up to 1867, was not far from one hundred pounds per capita. In England it was 189 per head, and in France 69¼ pounds. In the whole world the rate was only about twenty pounds per head. Since these estimates were made, the rate is thought to have increased to 223 pounds per capita in the United States, and 220 in Great Britain.

The Largest Steam Hammer.—There seems to be scarcely any limit to the power and weight of steam hammers. As soon as the largest is built, another, still larger, is immediately undertaken. The latest whose immediate construction is announced, has been projected by Krupp, which will be capable of beating up a mass of steel weighing 100 tons, and will cost one million of dollars.

The Brotherhood of Locomotive Engineers seems to be steadily increasing in numbers and influence, and bids fair to exert a most important and healthy influence over the large body of mechanics for whose benefit it has been instituted. The order now numbers 180 divisions. Its last annual meeting was held at Irving hall, N. Y., Oct. 20th.

The most ancient manufactories extant are said to be the glass works of Venice and Murano, which have had an uninterrupted existence of twelve centuries.

SCIENTIFIC PROGRESS.

Progress of the Sciences.

Our habitat is a world of wonders. The universe is a vast laboratory in which our brief lives afford us scarcely time enough to investigate our surroundings, to examine and admire the handiwork of the Creator, and to reverence him for his power, wisdom and beneficence. Here, by the way, we have a theology that cannot be counterfeited by the errors of repeated translations, or by the superstitions of Grecian mythology.

The natural or physical sciences have been cultivated by slow degrees. Each has been developed from seeming mysteries—each has had its stage of incipiency, and withstood the anathemas of the ignorant and bigoted. The wild Arabs gave us the rudiments of algebra, and six centuries ago these Ishmaelites and the Chinese devised the mariner's compass and the astrolobe. The Yzedies—devil worshipers—once held their curaivals on the ground afterward consecrated by Babyloo in her pride, and finally in her ruins.

Franklin caught the electric spark that now goes on our swiftest errands; traverses the various ocean; links two continents together, and makes of antipodes door neighbors. The incidental heating of a flask containing some fluid has brought enterprise, convenience and wealth to cover all the lands and waters of our earth.

Geology, though a young science, presents an attractive field for thought. It has hightened our conceptions and expanded our knowledge much in every way. Beyond doubt our earth is many thousands of years older than the Mosaic account, as formerly received, had led us to suppose. Whether our globe was formed from nothing by omnipotent power, or resulted from the condensation of gases, or was originally a molten liquid thrown from the burning sun, its ten strata mark many thousands of years. Fossils of animals have been exhumed from the solid rock, five miles deep, under the very spot where it is supposed Eden bloomed. Even our coal beds are the fossils of trees that grew before Moses' Adam had an existence. What then of the Siluriaa, Cambrian and Laurentian eras?

The microscope, as well as the telescope, has opened new worlds to our astonished gaze. How boundless the wisdom, the works, and the empire of the Deity! Let man, who stands midway between God and matter, for a moment look, with a telescope in one hand and a microscope in the other. Here, he beholds a vast system of infinitely ponderous worlds. There, he sees a world of animalculæ—creatures so small that a drop of water would make an ocean for millions of them—so diminutive that a battalion of them could drill on the point of a cambric needle! And yet these animalculæ are as various in their forms and characters as are the huge beasts that roam our forests and plains—each has a complex system of organs, and the adaptations and functions for digestion, nutrition and reproduction.

Now, we have confined life to the smallest possible compass; still it is a mystery that baffles all science. What is life? What the origin of living matter? Fallopias, of England, called it "vital force;" Beale called it "germinal matter;" Prof. Nelson, of Chicago, calls it "bioplasm;" and Huxley calls it "protoplasm;" and maintains, if I understand him, that life inheres in protoplasm, which is spontaneously generated by accidental combinations of oxygen, hydrogen, carbon and nitrogen, but in equivalents yet incognito. I believe that life can not originate spontaneously, and that its origin will ever remain a mystery to all but the Creator.

Now, looking again upward, and we muse. Strange! our mighty earth is not more than a grain of sand, compared with the systems of worlds we behold! By the use of the spectroscope the sun is found to be surrounded by a gaseous envelope, more than 4,000 miles thick. This is called its chromosphere, and consists mainly of glowing hydrogen; but in its deeper strata are found the vapors of sodium and magnesium. The moon has been really photographed, and in different lunations; her surface has been thus accurately mapped out, showing her mountains, valleys and rocks, but not her rivers, for she has no water.

Chemistry reveals volumes of startling wonders, and is a boon to the world of art and science. In photography and photogeny light has been chemicalized; but it is in the department of medicine that it has worked the greatest wonders and the greatest good. Medicine, though progressing slowly, has made a grand march, and achieved for mankind countless blessings.—*Ex.*

Animal and Vegetable Life.—The lowest forms or stages of animal and vegetable life—those consisting of single cells—so closely resemble each other that it is extremely difficult to distinguish the plant from the animal; their form, motions and contents are similar, yet one by development and growth becomes an unmistakable animal, the other a plant. Herein, it seems to us, lies the greatest obstacle for those to surmount who claim that there is no such thing as vital power. What but a distinguishing force—life—in each could determine and direct the wonderful results arising from these minute cells? There must also be two distinct phases of this force life—vegetable and animal.

A New Reagent for Gold.

Sergius Kern says: Studying the action of sulphocyanates on some double salts of gold, I have found a remarkably delicate test for gold; experiments prove that even less than one-fifteen thousandth of a grain of gold may be easily detected by using my reagent.

The gold is first separated from foreign metals, and next converted by means of sodium chloride into sodio-gold chloride; the solution is then concentrated by evaporation. In order to detect gold, an aqueous solution of potassium sulphocyanide is used, containing for one part of the salts about fifteen to twenty parts of water. About ninety-two grains of this solution are poured into a test tube, and some drops of the concentrated solution, obtained by treating the sample as described above, are added. If gold is present, a red orange turbidity is immediately obtained, which soon falls in the form of a precipitate; on gently heating the contents of the test tube, the precipitate dissolves and the solution turns colorless.

The reagent is so delicate that one drop of a solution of sodio-gold chloride (fifteen grains of the salt dissolved in 600 grains water) gives a very clear reaction.

This reaction showed the existence of very interesting double sulphocyanides of gold.—*Chemical News.*

Latent Heat of the Vapor of Petroleum. The average latent heat of vapor of petroleum has not been very satisfactorily determined, but it is known to be very low. Dr. Ure states it at 184, that of steam being 1,000, of alcohol vapor 457, and of ether vapor 313—that is, an amount of heat that will vaporize but 1 lb. of water, and about 2.2 lbs. of alcohol will vaporize 5.4 lbs. of petroleum (assuming on important change of specific heat during the change of state). By measure, the amount of heat or fuel that will vaporize one gallon of water should vaporize no less than 6¾ gallons of petroleum. This is an important practical point in this connection. The density of its vapor is very high, averaging, if the whole mass be converted into vapor, six and a-half times the density of air at the same temperature. At 500 deg. Fah. it will pass into vaporous form, except a trifling percentage.

Relation between Spectral Lines and Atomic Weights.—A correspondent of the *Scientific American*, writing from this city, cites a series of facts which appear to disclose an intimate connection between the Fraunhofer lines of the solar spectrum and the atomic weights of the substances whose glowing vapors they represent, which, if confirmed, he thinks, and justly so, will prove of the highest importance and interest.

The facts which he cites go to show a close relationship between the spectral lines of hydrogen gas and their atomic weights. The importance of the conclusions to be derived from the existence of such relations is apparent. The evidence of atomic molecules, when brought within the reach of scientific investigation, and their dependence on the general law of gravitation, would disclose the inner constitution of matter, the nature of chemical affinity and valency, and the nature of electricity and magnetism; and it would be instrumental in the solution of many problems.

A New Theory of the Nebulæ.—M. Plante has recently communicated to the French Academy of Sciences the results of some experiments which may lead, it is believed, to a new theory for the circumstances to which are due the spiral forms of many of the nebulæ. The experiments consist in the exact reproduction of these forms by the combined action of electricity and magnetism. Two copper electrodes of a battery of fifteen elements, being plunged in water acidulated to 1-10 with sulphuric acid, the end of the positive electrode is brought to one pole of the magnet. The cloud of metallic matter carried from the electrode by the current at once assumes in the liquid a gyratory spiral movement, of which the general disposition strongly recalls that of the nebulæ. The investigator is proceeding with further experiments in the light of this idea.

Tinning various Metals in the Humid way.—The following method is given by Wegler: A solution of perchloride of tin is first prepared by passing washed chlorine gas into a concentrated aqueous solution of tin salt, and expelling the excess of chlorine by gently warming it, then diluting it with eight to ten times its volume of water, and filtering it, if necessary. The article, well pickled in dilute sulphuric acid, and polished with sand and a steel scratch-brush, and rinsed with water, is loosely wound with a zinc wire, and immersed for ten or fifteen minutes, at the ordinary temperature, in the dilute solution of perchloride of tin. When tinned in this way, it is raised, brushed with a scratch-brush, dried, and finally polished with whitening. This applies to tinning cast iron, wrought iron, steel, copper, brass, lead, and zinc.

Greatest Power of a Horse.—A horse can exert his greatest strength in drawing in a straight line, being equal to twenty-seven men in this direction. This is seen in the way they draw loads on the road. In a circle a horse exerts his greatest strength with a diameter of forty feet. Reduce the diameter of the circle one-half, and you reduce the power of the horse two-fifths.

The Mining Share Market.

The stock market continues dull, tho sales thst are made showing very low prices. There has been no animation whatever dnring the past week in any direction, Ophir, the thermometer of the market, being almost stationary. Possibly the brokers who failed to get np a "fall rise" are waiting on their oars to get np the "spring rise." At all events little or nothing is doing in the market. We have in onr "Shareholders' Directory" ahout a dozen new assessments this week, and hnt one dividend, that of the Northern Belle mine. From whst is said in our editorial columns the resder may lesrn what is being done by the different investigating committees, which are stirring up their respective managements.

On the Comstock the local papers certify that everything is going on swimmingly. All the mills that were rnnning on Consolidated Virginia ore before the fire will he started np again shortly, viz: the Bacon, Trench, Woodworth, Brnnswick, Morgan, Occidental and Msriposa. The new California mill will also he pnt to work ss soon as the battery department shall have been completed, which will be ahont the first of next month. There is bnt one engine in the Consolidated hoisting works ready to run at present. The old assay office possessed a capacity snfficient for the assaying and melting of bullion to the amonnt of $1,000,000 per month; the new one will have a capacity of $4,000,000 per month.

On the Ophir every portion of the work on the machinery is being pressed to completion as rapidly ss it is possihle for it to be done. The hoiler house has been erected over the incline engine, and they are putting the hydraulic apparatus of their new ore dump in order. The pumping engine is in place and the fonndation timbers are ready for the reception of the heavy mschinery of the pump. The Winfield mill is steadily rnnning on the ore reserve, turning out hullion sufficient to pay all running expenses; and the appearances are that the mine will soon resnme its former prosperous condition.

The new mill of the California is fast approsching completion. The building is finished; the frame work for the hatteries and mortar beds in place; the smoke stacks np; the engine and other machinery heing rapidly placed in position.

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in the Mining and Scientific Press and other S. F. Journals.]

MINING SUMMARY.

THE following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

MONTREAL PLACER CLAIM.—Amador *Ledger*, Dec. 11: This claim is located beyond Jackson Gate, and adjoins the claim now being worked by the caual company. The owners are Messrs. Troeh and Belliard. For nearly two years the work has been confined to driving a tunnel into the hill, for the pnrpose of reaching the main lead of pay dirt. The tnnnel is now in a distance of 950 ft—about 100 ft from the point aimed at. It is expected to reach the desired spot in three weeks, when the enterprising owners oslculate npon realizing a snbstantial reward for the time and ontlay of the psst two years. Several minor leads have been out in running the tunnel, which were fonnd to pay fair wsges, bnt not snfficient object to delay the tunnel for the sake of working them. A perpendicular shaft connecting with the surface at a distance of 400 ft, supplies the tnnnel with a cnrrent of fresh air. Altogether this is oerisinly worthy to he ranged among the higgest boring nndertakings of the county. The claim hss been worked for over 20 years, and considerahle gold has been taken from it. Its richness has been demonstrated beyond a douht. It will yet require a life-time to work it ont.

HYNRAULIC CLAIM.—Dnring the past week we have taken the opportnnity of visiting the hydranlic claim purchased by the Amador canal company last year, which is familiarly known as the Martell's claim. It is situated some fonr miles from Jackson, and operations sre condncted ou a scale of msgnitude that completely throws in the shade all other efforts at hydraulic mining at present carried on in Amador county. There are facilities for throwing two streams of water; one is called the Little Giant, the other, thrown from a nozzle measuring 4½ inches in diameter, is appropriately termed the Big Giant. At the time of onr visit the latter was playing upon the claim, supplied by a flow of between 200 snd 300 inches of water in the hranch ditch. Work had been resumed hnt five days, bnt in this short space of time a large slice of the hill had been washed down the creek, leaving its precions contents in the slnices. The claim is reputed a rich one, and as the proprietors are enahled to work it at a very little expense, being the owners of the ditch, they will nndonhtedly reap sn abnndant harvest at the close of the season.

AMADOR MINE.—We are informed that the sinking operations recently carried on in the Amador Consolidated mine, of Sntter, have led to the discovery of a rich ledge, at a depth of npwards of 2,000 feet. The vein is narrow, bnt the rock is said to he of a richer character than any taken ont of the mine for a long time. Sinking has been snspended, and miners are now drifting on the lead.

LINCOLN MINE.—It is gratifying to learn that everything connected with this mine is looking well. Heretofore the rock for crushing hss been tsken principally from the upper levels. Now, however, the richest rock is being taken from the 600-ft level. The mill gets through its 90 tons of ore daily. The last clean np, made early in the month, wss considerably above the average.

BUTTE.

PURE GOLD.—Oroville *Mercury*, Dec. 10: At the express office (Tuesday last), we saw a $10,000 har of gold from the Spring Valley company's claims, that was valned at over $20 per ounce. A new piece of gronnd had been worked and a few hoxes were cleaned np to see what the clsim was paying. The excellent qnality of the gold, and the ahnndance of it, if the small piece of gronnd worked is a sample of the balance, gives promise of a rich harvest. It was sent below to the mint.

ELECTRIC MINING COMPANY.—It has been some time since we have mentioned anything abont the above company's doings, as their mill has been standing idle for a number of

months, on accoant of the scarcity of water last summer. Nevertheless, as we lately learned, they have not been quiet altogether; they have improved their mines, taking ont large qnentitica of good ores, and to prevent a repetition or stoppage of their mill in the future, they have erected a snbstential dam in the South fork, abont a quarter of a mile above their mill. They possess now as good a water-power as they oan desire, not alone for the present capacity of their mill, bnt enough for hundreds of tons, and at the lowest stage of the river—enough water to redace from twenty to thirty tons per dey. It is now only a question of time for them to increase their milling facilitiee according to the power they possess at present. They are now busy in building e flume aad nn overshot wheel, the castings for the latter baving arrived at the railroad warehonse. They intend to heve all ready in as short a time as possible, to make a long and steady run in the work of redncing their ores.

CALAVERAS.

West Point District.—Calaveras *Chronicle*, Dec. 11: Charscter of the ore in the Cheene is improving. The country rock is now working easier. The Constancia looks very promising, judging by the qnartz on the dump. Tho Mina Rica has now gained very extensive backs, aggregating 115 ft in depth, measured with the inclination of the lode. Preparations aro being made to start levels near the bottom of the shaft, which is about 250 ft in depth. A large quantity of first-olass ore has accamulated on the dump from sinking the shaft alone. Tho mill will resnme crushing as soon aa the roads are in condition to haul ore.

Glencoe District.—Over 50 toua of quartz from the Herryhousen mine were crushed at Garland's mill, yielding a fraction over $30 per ton. The first-class oro is still lying on the dump, as the custom mills are not of sufficient capacity to snit customers. Captain Woodworth's new hoisting works, on the Grasshopper, are nearly complete. The engine rates at 16-horse powor, bnt it is estimated that it will work the mine at least 300 ft deop. The hoisting works have been constructed in an economical manner. The old workings are only 93 ft in depth, showing two separate ore chutes, which have yielded rock worth $140 to $190 per ton, respectively. Some 500 linear ft from this, another fine ore chnte haa been worked which is very extensivo but not quite as rich as the former two. Mr. Woodworth bought the mine at a comparatively very low figure. A new tunnel is being run on the Monte Christo. The Rickman mine has well filled dumps of fine ore, witb extensive reserves. Good authority states that the Glencee Consolidated will be worked on a very large scale. The San Bruno, Good Hope and Monte Christo were examined last week by an experienced agent of a heavy Washoe miniug firm. The present owners of thoee minea are not able now to carry on the costly developments which are necessary hereafter. The San Bruno has a substantial and well earned reputation as a first class mine, but its works are in a sad condition for future nse. The Hadlock mine commenced a new shaft last Thursday with a view of making extensive developments. The pay ore is from 3 to 6 ft in width, averaging in the vicinity of $30 per ton. Partnership complications have retarded developments heretofore.

CONTRA COSTA.

New Coal Strike in the Pittsburg.—Contra Costa *Gazette*, Dec. 11: By a tnnnel of some 700 ft, which they have been nearly a year in running from the lower level gangway of the Clark vein, the Pittsburg company struck the Black Diamond vein on their ground last week, finding it nearly 4 ft in thickness and the coal of remarkably fine quality. They have a lift of about 400 ft above the tunnel level, as is reported, and feel well recompensed for the outlay made in reaching the vein.

The Empire Coal Mine. — The new coal mine, called the Emnire, belonging to Messrs. Hawxhnrst & Ronse, is thought to he one of the very best yet opened in the county. The location is some two milee east of Somereville, in one of the little valleys opening on the plains. The mine is opened by a slope on the vein, now down abont 400 ft. The vein is said to be 4 ft or more, and the coal of very snperior qnality. The engines for pumping and hoisting being now ready for operation, the work of raising coal and the further opening of the mine is to be vigorously proaecuted.

EL DORADO.

Woodside.—El Dorado *Republican*, Dec. 9: By the breaking of the pump about two weeks ago, the Woodside mine was obliged to shut down. A large cornish pump is now being put in, and steam will doubtless be got up again within a week, and as soon as the water oan be got out work will be resumed in the lower depths, where good pay rock was being extracted at the time of the accident to the old pnmp.

We understand that arrangements have been made for thoronghly developing the Young Harmon mine. This mine has every indication of being valuable, and if properly worked .we believe will prove so.

INYO.

Coso District.—*Coso Mining News*, Dec. 11: The Defiance mine continues to improve in a most remarkable and satisfactory manner. The ledge has now heen prospected hy drifts run npon it for a distance of 265 ft along its course from north to south, and throughout this entire length the very best of ore has been extracted. No breaks have occarred to disturb its continnity, and the indications are all favorable for it to continue on its course without disturbance. In fact the further the explorations go the more solidified becomes the ledge, while the ore improves in quality. At the bottom of the winzs, which is 60 ft below the first level, a drift has been run south for a distance of 30 ft, and at this point was encountered the rich ore spokon of in our last week's report, and it was determined to cross-cut and ascertain the width of the ledge. This cross-cut has now penetrated a distance of 30 ft and no signs of the foot wall appear, and the ore is of average richness, higher than any yet found; the last assays showing returns of $416.16 in silver and 45 per cent. lead to the ton. The mine is looking extremely well in every quarter, and is now opened sufficiently to produce 1,000 tons of ore weekly, if it is required to turn out this large quantity. The ore teams are running constantly and regularly and transporting daily more than the furnace can smelt, while the indications are that no interruption will occur during the winter to stop the transit of ors.

The Bella Union mine discloses new treasures every day, improving with the advance of every foot, in width and extent of vein and quality of ore. It oan now be nuresorvedly ranked as one of the leading mines of Inyo county, for the explorations have demonstrated beyond any farther question its permanency and warrant the immediate erection of hoisting works to enable them to raise ore from the numerous openings. This is now essentially necessary, and when procured should be erected over a working shaft of proper dimensions that should be started as soon as it is decided to order the hoisting works. The work has now reached a point where it must proceed slowly if the extraction and raising of ore is further prosecuted, for the lower level is glutted with it taken from the cross cuts and left to enable them to remove the ore and material taken from the face of the drift.

Lookout District.—We learn that J. R. Norton and James Kyle have purchased in the Kearsarge mine in the above district, paying for 300 ft the sum of $3,000. There are many very rich mines in that locality, which when once prospected will develop into most excellent property, and we are pleased to note the fact of transfers being made to parties who will endeavor to make them productive.

NEVADA.

More Rich Rock.—Nevada *Transcript*, Dec. 11: Last spring Curry & Blam discovered, in working a ledge located about two and a half miles from town, near Rush creek, some very rich rock, out of which they got several thousand dollars in a very short space of time. They worked out the richest part of the rock as they supposed, and Mr. Blum sold his intereat to T. C. Randall, who, in company with Mr. Curry, has continned prospecting up to the present time, most of the time, we believe, doing dend work. This week they went back to the point the rich rock was taken out before, and commenced stoping, when they discovered that they had run across and over the ledge, and that on the back side of the shaft it continues as rich as ever. They took out $300 in abont an hour after they discovered the fact, and have in all taken out ahout $1,500 during the few days since they struck the deposit. The ledge is three feet thick, and through the center is a streak of rock composed mostly of gold. How far it rnns they do not know, as they have not drifted much since they fonnd it. They have taken out three tons of rock, besides the rich specimens, and it looks rich enongh to pay several hnndred dollars to the ton. When they quit the place last summer they were not over a foot from the present rock. Mr. Curry informs us that the appearance of the ledge indicates that the deposit is extensive. Some of the specimens are composed almost wholly of gold, and enongh is in sight to guarantee a good stake to the enterprising and persevering owners.

Gold.—The effects of the late rains begin to be realized now. Nearly all the mines of the county are at work with a full force. Gold dust has begun to come into market, as any one can find out hy stopping aronnd the bank a little while. It is the beginning of a stream which will continne to flow steadily nntil next September, and will do more to solve the financial problem than all the speeches and newspaper editorials which have been written or delivered for the last year. After all, the miner, with his pick and shovel, is the ablest financier. He goes in for hard money, and has no difficnlty in making people believe that it is the best circnlating medium. He does not counsel a return to specie payments, because he never made any other, and he is not perplexed to discover a means to bring it about or keep it up. The jingle of his gold dust is more musical and eloqnent than the tones of the most eloqnent financier in the land.

The Manzanita mine started up over a week ago, and is now using 15,000 inches of water, which will be continued throughout the season. Other mines in the vicinity have also been washing. Everything ought to be crowded now. There is plenty of water and bushels of treasure in the hills, waiting to he washed out. The country needs the gold, and we believe owners of mines have a hankering after it too. Turn on the nozzles.

PLACER.

Nugget.—Placer *Argus*, Dec. 11: John Burke washed out an $84 nugget the other day, near town. There is still some gold in the ravines around Aburn. A short time ago a young man named Jacob Keiser came to this place from Missouri, and went to work in North ravine. He fonnd a nugget worth $17 the first day, besides fine gold enough to pay him well for his work.

The Auburn gravel mine still holds its own, as being one of the best mines in the county. All reports of it are very favorable, and it is not to be doubted that its owners will be liberally rewarded with the precious "color." On last Sunday a blast of 100 kegs of powder was set off, directly after which washing was resumed. The prospects continue good and the results are satisfactory to all concerned in this mine.

Mining Items.—Dutch Flat *Forum*, Dec. 9: The various claims heretofore mentioned as having commenced operations, namely, the Yankee, Jehoshaphat, Central, Lekamp and Pacific, still continue washing. The Summersett and Elmore Hill claims have since started up. We can now say that our washing season has fairly commenced, and so far has opened as favorably as the most noted growler could ask. The weather has been warm and favorable for mining and the quantity of gold now being accumulated in the sluice boxes of the various claims must be immense. The superintendents are anticipating large returns and the results of approaching clean ups will be watched with interest. In the Yankee claim, Supt. Lindlum is having four powder drifts run, which will be completed in about two weeks, wherein he intends to explode about 500 kegs of powder. In the Jehoshaphat claim the pipes are turned against a large body of blue gravel loosened up by a blast which was exploded the last season. The gravel has become more or less slacked and will in all probability pay largely. The Yankee, Boston, Franklin, and Buckeye tunnels are being driven with all possible speed. In the latter the contractors have commenced to raise an incline, and we may expect, in a short time, to have the Buckeye as one of our gold producers. The ditches of the Miners' ditch, South Yuba canal and Cedar creek companies are all running as full of water as prudence will permit. As a whole, the outlook for the approaching winter is unusually encouraging to our miners. A great many men are being employed, and our merchants anticipate brisk times for the future.

PLUMAS.

A Splendid Water Season.—Plumas *National*, Dec. 4: The frequent and continuous rain storms give promise that the present water season will be the best for many years, and the miners are in the very best of spirits, and confident that the next few months will put them in easy circumstances, and also enhance the value of their claims. We think their hopes are certain to be realized, for there is no doubt of the richness of the Plumas mines, and most of the hydraulic claims are well prepared for work. The cry of "hard times" will soon be over in this part of the country.

Runs Nicely.—Richard Jacks, of Meadow valley, was in town the other day, and informs us that the Golden Enterprise is prospering. The question as to whether the big flume would stand the high water has been thoroughly settled, the recent heavy floods not having injured it in the least.

It is rumored that the Providence Hill company contemplate bringing the water of Mountain Meadows creek to their ground on Rush creek. As the cost of pipe, ditches, etc., would amount to about $250,000, this will be an extensive operation, bnt we are assured that there is a strong probability of the work being inaugurated, and st no very distant day.

Items.—Heavy rains have been in order for the past week, and the ground is thoroughly saturated. Let it come. The miners can stand it. The Hnngarian Hill company now have their pipes in full blast, and we expect to hear of some good results from that quarter this season. The North Fork company have been getting in a huge quantity of supplies, and are now fitted up to run until July next. Garland has commeaced piping in his lava bed claims near Spanish ranch. Dick has got some valuable ground, and we hope he'll make a fortune. The Light's canon miners are getting to work, the rains having started up the water. Some of the best mining ground in the county is located in and ahout Light's canon. The water has started on Massac, and Galpin is again at work on the "bonanza." He has got a good claim and will make money at a lively rate this season.

SAN BENITO.

Started Up Again. — Hollister *Enterprise*, Dec. 11: Work in the Picacho mine, owned by M. Cody & Co., has been resumed, and late developments are very flattering. A conditional sale of the property was made a few months ago to an English company, but they failed to carry out their egreement, hence the mine has recently been unworked. Abont 100 flasks have been smelted, and large quantities of good ore are lying on the dump. Some twelve or fifteen hands are employed in running tunnels and excavating ore. Mr. Cody is one of the most competent and energetic mine managers in the country snd under his snpervision the company may confidently anticipate the best possible results. This property bids fair to be very valuable, and as it is in San Benito county, we may look forward to its contribntion to onr revenne.

SIERRA.

Rumor.—*Mountain Messenger*, Dec. 4: It is rnmored that the Bald Mountain company have sent for fifty Chinamen to work in their claim in place of that many white men. We hope, for the sake of business men of Forest City, that the rumor is not true.

Gibsonville.—Pen Haven gravol diggings, main tunnel in 700 ft. The company will soon be ready to take out pay gravel. Works in good order for winter. Union claim, Mt. Pleasant, paying well. Keiffer & Emerten, working large force of men. Boot-Jack and Chalcedony companies putting in many improvements. Very little snow this week at Gibsonville.

Newark.—North America company busy at work washing gravel; said to pay well.

Some Monitors.—There are three monitors working at Morgan & Donahue's diggings, St. Louis, and two at the Pioneer claim, Gardner's point.

Howland Flat.—Fashion claim, Cold canon, paying well. Five men took out last week 17 ounces of gold. Alex. McNee, T. McFarland, Wm. Stone and M. A. Norton, owners. Prospect of its paying an ounce to the pick per day before Christmas, as the richness of the gravel to all appearances seems to be steadily increasing. Empire company's dividends as large as ever. Chittenden, Stephen Jackson and Jacob Small have pipes all laid, reservoirs all completed and tunnel in 150 ft. Will be ready for active operations by next spring. Gurly & Thatcher are piping in the old California claim, and doing well. Sears Union water company, ditto. Virginia company, Potosi, are opening a drifting claim, adjoining the Empire on the north, about 500 ft from their line. Calculate to strike pay next fall, about 1,300 ft more to run. Surveyor Jones busy drawing lines for the Empire. Tom McFarland has thanks for a rousing dinner, which, to his credit he it said, he cooked himself. We put him up against the best cook in the county, and bet on him every time.

Rising Sun.—The Rising Sun company, Mt. Vernon, adjoining the Green Mountain, supposed to be equally as good, cleaned up during the past fifteen days 24¾ ounces, averagely coarse gold; total amount of work, 40 days with three men.

Mt. Pleasant Ranch.—Iowa diggings nearly clear of water; boys working steadily, with bright future ahead; depth of new shaft, 301 ft; 13 men employed; new pump, costing $1,100, down 270 ft; old pump valued at $650.

TRINITY.

Notes North.—Trinity *Journal*, Dec. 11: "Water, water, everywhere," between Weaver and Trinity Center. Ditches, creeks, gulches and everything else where water can run are filled and the ground is thoroughly soaked.

The miners here are still preparing for work ahead. On Shoo Fly hill the company is working away with might and main. Negotiations are pending in regard to payment on the old Coyle claim, a settlement *in toto* having been nearly effected. Mr. Edward Allison, now proprietor, is at the Center, full of jollity and hopes for the future. He will soon begin operations at the claim.

The large retorts have been removed to Cinnahar—three of them for the Boston company and five for the Altoona. The latter company, from crude ore, during the month of November, turned out 78 flasks of quicksilver.

Nevada.

WASHOE DISTRICT.

Lady Bayan.—Gold Hill *News*, Dec. 9: The new pump station at the 500-ft level is nearly completed. The north and south drifts, on the 380-ft level, are steadily advancing, the face of the south drift being still in a fine character of White Comstock quartz with spots of excellent ore. The east and west cross-cuts from this drift, 380 ft south of the shaft, are also in fine quartz.

Julia.—The main southwest drift on the 1500-ft level is rapidly advancing, the face in quartz and porphyry, carrying some fine streaks of ore. The main southwest drift on the 1400-ft level is also making good progress, the face in a much better character of quartz and ore. The face of the cross-cut from this drift is also in a much more encouraging quality of quartz. The chances are that the Julia may find paying bodies of ore almost any day.

Amazon and Glasgow.—Sinking the shaft is going rapidly forward. It is now down 288 ft. The north drift from the 259-ft station is in 77 ft, following the hanging wall of the ledge, showing the ledge to be well defined and carrying good ore almost the entire distance. At the rate the shaft is being sunk it will be but a very short time before the company will be ready to open another level, when some rich ore developments are looked for.

Lady Washington.—Three or four days ago a splendid streak of vein matter, consisting of clay and quartz carrying metal, came in at the north side of the shaft, and to-day the whole bottom of the shaft is in the same very promising material. Water increases, but the very powerful machinery is capable of handling twenty times the amount met with at present.

Buckeye.—Sinking the main incline is making rapid headway. A winze has been sunk on the ledge 100 ft south of the 550-ft station, which is down 22 ft, the bottom in fine quartz and ore. The prospects are excellent for the opening of a good mine on the next level below.

North Carson.—This mine has shown decided improvement during the past week, especially in the winze below the upper tunnel, the bottom of which has run into a body or seam of ore over 10 ft in width. This ore is superior to any heretofore found in the mine, being more of the Comstock character, such as is found in the upper workings. The lower tunnel is to be pushed ahead more vigorously

(Continued on Page 396.)

School and Mineral Lands.

The *Territorial Enterprise* gives the decision of the Supreme Court of Nevada in the case of Solomon Heydenfeldt sgsinst the Daney gold and silver mining company. The case involved the title of the State to the sixteenth and thirty-sixth sections of the unoccupied public lands granted to the commonwealth by Congress, where the same embrace mineral lands. The Supreme Court considers it one of unusual interest, involving principles of great importance, and says it was ably argued by learned counsel and received the careful attention of the court. The title to a large number of these sections had been secured by persons under the assumption that Congress had secured them to the State for educational purposes, regardless of the fact that many of them contained valuable mines. This opinion was hooked by a decision of the Supreme Court of California; but is now set aside by the Supreme Court of this State, which decides in effect that these school sections cannot be claimed by the State when they contain minerals. This opinion is by Chief Justice Hawley, and is concurred in by Judge Earll. Judge Beatty differs from the majority of the court on some points, and is of the opinion that all the sixteenth and thirty sixth sections, whether mineral lands or not, belong to the State, unless they have been disposed of by act of Congress prior to the passage of the Enabling act, by which they were granted to Nevada. He does not think, however, that the appellant can derive any advantage from this conclusion, for the Legislature has acquiesced in the Congressional interpretation of the grant, that it does not embrace the mineral lands, and has agreed that they shall be reserved from sale. He therefore concurs in the opinion of the court in the case at issue, which was an action of ejectment to recover a portion of the sixteenth section, in which the Daney mine is located.

State Lands and Agricultural Products.

A volume of reports has recently been issued from the office of the Surveyor General, containing much valuable statistical information in regard to the present acreage and agricultural resources of the State. In these reports the total area of the State is estimated at 100,500,000 acres, or 157,031¼ square miles. This is 30,000 square miles below the estimates of former years. Of this area, 2,648 townships, or 41,627,759 acres had been surveyed prior to June 30, 1875, and 46,611,000 acres remained unsurveyed. The swamp and overflowed lands are put at 1,720,000 acres, of which 1,553,115 acres have been returned as such by the United States Surveyors.

Federal Land Grants.

The grants of land made to California by the United States are approximated at 7,590,035 acres. Classified—500,000 acres are entered under the head of internal improvements, 1,553,115 as swamp and overflowed lands, 5,229,440 for Thirteenth and Thirty-sixth sections, 46,080 as seminary grant, 6,400 for the erection of public buildings, 150,000 for the benefit of agriculture and the mechanic arts, and 105,000 as salt marsh and tide lands. This makes a territorial area of 7,598,030 acres, or 50 per cent. greater than that of the state of Massachusetts, which State covers but 4,922,000 acres.

Lands Sold by the State.

During the last two years the State sold 100,934 acres of swamp land; of which 31,785 acres is in Kern, 26,250 in Tulare, 17,259 in Lassen, and 8,005 in Plumas; making 83,309 acres for these four counties, and leaving for 20 other counties 17,626 acres. During the two years ending August 1, 1875, there were 79 swamp land districts organized and reported at the Surveyor General's office.

Swamp Lands Reclaimed.

The reclamation is reported "complete" in 27 out of a total of 187 districts organized since the passage of the Reclamation Act of 1868. The acreage of these 27 districts completely reclaimed is 118,255½. That is, about 1 acre of every 12 of this sort of land in the State has been completely reclaimed. In 55 other districts $2 per acre has been expended in the work of reclamation. These 55 districts cover 442,441 acres. The amount of money refunded to purchasers under the law is $248,578.93.

Area and Products of Cultivated Lands.

The agricultural and horticultural statistics, incomplete as they must be, are nevertheless highly interesting. In 1873 there were 3,366,716 acres of land in cultivation, and 3,541,900 in 1874, an increase of 205,184 acres, or about 6⅛ per cent. in a year. A like per cent. of increase for 1875 would give us a present area in cultivation of 3,758,841 acres. The acres in wheat last year were 2,156,149, or about 62 per cent. of the whole area in cultivation. The area in wheat and barley was 75 per cent. of the whole area of cultivation. The wheat production for 1873 is placed at 28,784,571 bushels; for 1874, at 30,248,341. The acreage in barley in 1873 was 496,217; production, 11,063,564 bushels. In 1874 the acreage was 490,274; production, 9,261,940. Acreage in oats in 1873, 74,729; production, 2,077,804 bushels: in 1874 the acreage was 65,217, and the production was 1,683,150 bushels. The ten counties foremost in the production of wheat and barley in 1874 were as follows:

	WHEAT.		BARLEY.
Butte, bushels..	3,170,600	Sutter, bushels....	616,416
San Joaquin	3,050,000	San Luis Obispo..	1,053,800
Stanislaus.....	3,002,000	San Joaquin.....	625,000
Colusa.....	3,000,000	Alameda.....	516,282
Sonoma.....	2,624,250	Monterey.....	508,500
Monterey.....	2,430,500	Yolo.....	503,780
Yolo.....	2,056,135	Stanislaus	460,000
Santa Clara.....	1,701,131	Tulare.....	446,190
Contra Costa....	1,500,830	Butte.....	442,300
Sutter.....	1,284,688	Los Angeles.....	388,600
Total 10 counties.	23,824,104	Total 10 counties.	6,458,868

The above ten foremost wheat counties yielded in 1874 very nearly 79 per cent. of the entire wheet production of the Stete—(78 5-6 per cent.) The ten foremost berley counties yielded the same year very nearly 59 per cent. of ell the harley produced in the State.

The Hop Crop.

Santa Clera comes first in hops, 431,277 pounds; Sacramento second, 367,500 pounds; Mendocino third, 192,000 pounds; and Alameda fourth, 82,000 pounds. The four counties yielded very nearly 80 per cent. of the entire production, 1,346,894 pounds.

The Tobacco Crop.

Los Angeles produced 10,000 pounds, San Benito 190,000 pounds, and Santa Clara 802,793 pounds, being all the tobacco raised in the State in 1874, but 69,941 pounds.

Comparative Statement of other Agricultural Products.

In 1874 we had a yield of corn from 40,992 acres, of 1,449,002 bushels, against 1,307,679 bushels from 39,594 acres in 1873. The following tabular comparison of various products for 1873 and 1874 is collated from the report. It will exhibit in the shortest method the progress made in the industries covering the productions given:

	1873.	1874.
Peas (bushels).....	78,076	106,628
Peanuts (pounds).....	287,954	161,200
Beans (bushels).....	162,379	169,155
Castor beans (pounds).....	145,600	123,400
Potatoes (tons).....	183,000	131,321
Potatoes (acres).....	24,704	25,449
Sweet potatoes (tons).....	5,236	4,998
Onions (bushels).....	81,052	110,385
Onions (acres).....	912	869
Hay (tons).....	566,144	752,214
Flax (pounds).....	1,405,080	2,239,800
Hops (pounds).....	899,660	1,346,894
Hops (acres).....	847	1,125
Tobacco (pounds).....	1,071,030	1,243,734
Butter (pounds).....	6,822,091	6,924,140
*Cheese (pounds).....	1,722,328	3,412,642
Wool (pounds).....	19,633,813	21,340,482
Honey (pounds).....	529,679	897,060
Grapevines	30,196,429	35,182,501
Wine (gallons).....	3,858,027	3,892,775
Brandy (gallons).....	176,944	223,763
Whisky (gallons).....	1,347,700	1,763,150
Breweries.....	144	170
†Beer.....	4,386,672	14,633,354
Horses.....	243,711	230,522
Mules.....	23,629	23,557
Cows.....	302,366	288,938
Beef Cattle.....	182,796	195,378
Oxen.....	47,793	8,804
Neat Cattle.....	794,073	848,585
Sheep.....	4,898,001	5,464,711
Hogs.....	219,939	242,819
Grist mills.....	204	225
Barrels flour made.....	1,714,218	2,016,803
Bushels corn ground.....	234,940	269,237
Feet of lumber sawed.....	442,018,387	446,371,490
Woolen Mills.....	8	8
Pounds wool manufactured.....	5,601,976	3,865,995
Railroads (miles).....	1,214	1,326

*The increase in the production of cheese and butter from 1873 to 1874 was remarkable—particularly in cheese. The increase in wool was 9¾ per cent. An equal increase for this year will give us 23,316,000 lbs., and very nearly 6,000,000 sheep. The leading sheep counties are Los Angeles, Fresno, Kern, Santa Barbara, Merced and Tehama. The leading cattle counties are Kern, Santa Clara, Fresno, Monterey and San Luis Obispo. The dairy counties are Sonoma, Marin, San Mateo, Sacramento, Plumas and San Luis Obispo. In 1873 the assessed property of the State was $611,256,939; in 1874 it was $655,036,235.

†San Francisco was omitted in the report of 1873.

ANOTHER BONANZA FOUND.—Intelligence was brought from Treasure hill on Wednesday morning last that another rich bonanza had been struck in one of the Eberhardt & Aurora company's workings. Of course this was welcome and joyful news to the citizens of Hamilton, as this company at the present time is our main support, and everything that is beneficial to them is also a god-send to our people. It is stated that the find did not so much astonish those connected with the mine as it did the outsiders, for a 200 feet drift was being run to strike the ledge that was found. The ore just discovered is at a depth of 280 feet, or about eighty feet lower than any body of ore was ever found in the workings, and is pitching eastward, or into the hill, which is a contrary direction to all other bodies of ore heretofore found. At this writing no idea of the extent of the find can be approximated, but Foreman Maxwell has seen enough to warrant him in giving the workmen a "blow out" down in the mine. The character of the ore is very similar to that found in the Eberhardt in early times, and should it prove to be a large body, as is confidently expected, the company have indeed found a very rich bonanza. We hope to be able in our next issue to give all particulars in regard to this new discovery.—*White Pine News, Dec. 4th*

NEW HOISTING WORKS.—The new hoisting works at the Richmond mine are nearly completed and will be ready for operation some time during the present week. They are said to be the finest works in the State, and they are certainly the heaviest of any, with the exception of some upon the Comstock, being of a sufficient power for hoisting from a depth of 2,000 feet.—*Eureka Sentinel.*

Pancake Coal Company.

J. Montgomery, the great furnace and quartz mill builder, and general mechanic, returned here from Pancake on Wednesday last, where he has just completed for the company extensive hoisting works. He has also been remodeling the engine, which now works from a friction to a link motion, reversible. Some time ago this company let a contract for sinking a new double shaft, nine by four feet and a half in the clear, to a depth of 300 feet. One hundred and forty feet of contract has been completed, and one hundred feet of the shaft is now timbered. They are now sinking at the rate of four feet per day, and when twenty feet more will have been completed, they expect to strike the first layer of coal. At a depth of 260 feet they will strike the large body of coal that has been developed by the old workings. A great amount of work has been done on this mine, but it was performed in a very unskillful manner, and it was deemed best by the present owners to sink a new shaft and commence working the mine in a more scientific way. The old workings are at a much greater depth than the new, and have developed two fine layers of coal. The hoisting works just erected are calculated to work the mine to a depth of 600 feet. Mr. Welch, the superintendent, expects to deliver 1,000 tons of good, merchantable coal in Eureka by the first of July next. The company is now using the coal for all needed purposes about their engine at the works, and say that it burns splendidly. Now that wood is becoming scarcer every year, and has to be hauled long distances, the coal from this mine will be of much benefit to the town of Eureka, where they are using such large quantities of wood, and which will probably be a much more economical fuel. We have a great abundance of wood at present, but the amount that will be needed during the next year or two, by our mills and furnaces, will draw heavily upon the supply, when this coal will also be of great benefit to our people. Even for domestic purposes every one would prefer coal to wood.—*White Pine News.*

MAKING BOXES.—The Swiss have a clever way of making cheap boxes without the use of nails, the mitred sides being fastened together by wedge shaped pieces of wood. An English inventor has recently patented another process, which may be used for heavy as well as light boxes. The two pieces of wood to be fastened together are first mitred in the ordinary way, and a hole is then drilled in each piece vertically from the bottom upward at a short distance from the mitred edge. A channel or groove is then cut by a saw or otherwise from the mitred edge to the drilled hole. This channel is of less width than the diameter of the hole, and may be cut either parallel to the sides of the pieces of wood or at right angles to the mitred edge, so that when the two edges are put together there shall be a continuous channel from one side to the other, shaped somewhat like a dumb bell, add running from the top to the bottom of the box. A key is formed by running a fusible metal, such as lead, into this channel. The key may be made separately of solid metal and driven into the channel—but, in either way, a joint is formed which can be broken only by tearing away the mitred edges of the wood.

ALE AND PORTER.—There seems to be quite a mystery in regard to some of the constituents of ale and porter. At present chemical science is completely baffled by the ingredients. All that is known with certainty respecting the composition of these liquids is that they contain some marvelously intoxicating elements, but what these elements are no chemist can yet tell. Mr. Anderson, the English analyst, in his last quarterly report, states that ale and porter—the latter especially—have for a long time continued to show insupereble difficulties as to the detection of the ingredients used in place of malt and hops. "The cause of the peculiar intoxicating effects of porter, for instance, cannot," says Mr. Anderson, "for one moment be supposed to result from the almost minute and surprisingly small amount of alcohol I find contained in that class of beer; yet a quart or two of it will produce more decided drunkenness than brandy or whisky containing twenty times that amount. I am sparing no efforts to find the nature of the substances which exercise this remarkable action—a point, I may mention, which has hitherto puzzled not only chemists, but those of the Inland revenue department, who from long experience, should know all about it." In the mean time it seems unfair that persons becoming stupefied on the unknown ingredients of drugged ale or porter, should be liable to the same penalty as those who get fairly drunk on alcohol. The culprits are the publicans who sell the mysterious drink, and who, in strict justice, should be heavily fined for the drunkenness of each customer.

ANTIMONY DISTRICT.—We learn from an authentic source that the antimony mines of Gilbert, Graves and Goodell, in Antimony district, south of Pleasant valley, have been leased by a French company in San Francisco for one year. The company agrees to pay the owners of the mines a certain price per ton for all ore extracted during that period. As we understand it the lessees intend to work the mines and commence shipping ore without delay. There is said to be plenty of ore in sight, and undoubtedly this company will ship enough to supply the demand in San Francisco.—*Silver State.*

Using the Raw Material to the Utmost.

One of the greatest discoveries ever chronicled is that of petroleum. Its importance is even yet but half comprehended, as illustrated by the following from an exchange:

Nature's economy, in all of her productions, is in no instance more strikingly illustrated than the varied merchantable commodities that are wrought from crude oils that are so bountifully deposited in some sections of our country; and the great waste that attended its treatment would do for an excellent text for a telling sermon on the startling ignorance of man and its rapid disappearance under the incisive application of his intellect. Upon the first discovery of the oil in the Pennsylvania districts, of course immense quantities were lost while yet in a crude state, owing to the inadequate means and contrivances for preserving it; then in treating the product the residue in the stills of the refiner was regarded as fit only for fuel, this was, however, soon found to be an error, and the tar was taken from the oil refinery, submitted to another treatment, and parafine oil is the result; again, a residuum was found, and this in its turn is now pressed and refined and enters largely into the manufacture of candles; submitted to a still further treatment, the wax becomes a transparent and tasteless mass, in which condition it is converted into chewing gum. After undergoing all these varied treatments there still remains a hard, crisp cinder, which still contains sufficient live matter to render it combustible and fully equal to the best coal in its heating qualities, and this, notwithstanding the fact that in its later treatment the mass is submitted to a white heat, which we would naturally suppose would so thoroughly disintegrate the matter and render any residue unfit for any purpose, much less a fuel. What science may yet accomplish in drawing from this cinder an article to swell the list of analogous products is as yet undetermined, but we are not prepared to believe that even this mass, although it leaves scarcely a vestige of ash after being burned as a fuel, will be allowed to go to waste.

PALACE HOTEL STATISTICS.—P. M. Wellen, as foreman, had charge of receiving all the wood-work of the Palace hotel, of which he kept a regular account. In summing up he finds some interesting facts, for instance: There were 298 miles of mouldings used in the interior, around the doors and windows; 101 miles of casing to doors and windows; 26⅛ miles of base-boards, and 22¼ miles of door jambs. There were 1,963 window frames, 3,441 pairs of sash, and 60,126 feet of inside blinds. There are 2,125 turned and fluted columns in use as supports to the corridors, dining and breakfast-rooms, office, halls and bay-windows. The sky-light over the court is 88x144 feet, the largest in the world. The glass is supported by 3½ miles of sash bars. The millions of brick, barrels of lime and cement, the tons of iron and tons of putty are not included in this statement. It is 136 feet from the lower floor to the top of the ridge pole of the sky-light.

NEVADA PLACER DIGGINGS.—The *Silver State* says: The late storms have increased the flow of water in the ravine near the Eagle mine, in Spring valley, and the placer miners who had to suspend operations during the dry season are preparing to resume. The men who worked these mines, almost without exception, made fair wages, and if water can be had, no doubt they will again do so until the weather becomes too cold. We are not advised as to the extent of the diggings, but it is believed that with plenty of water all the gulches in the vicinity would pay wages. Indian creek, which finds its way into Buena Vista valley, a few miles north of Spring canon, affords several large sluice heads of water for several months in the spring and summer, and it can be conveyed by a ditch to the diggings. All the placer mining heretofore carried on in Spring canon has been by the antiquated "rocker" system, and the gravel must be rich to pay even four or five dollars a day to the miners engaged in the business of washing it.

SAND PAPER.—One of the old industries, the nature and extent of which are comparatively little known, is the manufacture of sand paper, the amount of which article annually produced in the United States is estimated at not less than 200,000 reams, including the various grades and qualities. Formerly it was made of ordinary brown paper, glue and sand. At present, for the most part, the paper is made of old rope, the best quality of glue is used, and, instead of sand, pulverized quartz or flint. By this means a superior fabric is produced, of a constantly uniform grade, and at so low a price that the use of it has become greatly extended, large quantities being exported to Europe, South America, the Pacific islands and elsewhere. For emery paper and emery cloth a large demand has been created by the finished iron works in steam engine shops, the sewing machine factories and other similar industries which require them for polishing purposes.

AMERICAN PASSION FOR FLOWERS.—It is stated that more bouquets (not buttonhole) are made up in a single month in the city of New York than in the course of a whole year in the city of London. This is, perhaps, a trifling exaggeration, but Mr. Dickens said very much the same thing in writing of his American experience several years ago, so that it is evident that our love for flowers is sufficiently conspicuous to attract the attention of foreigners.—*Horticulturist.*

Useful Information.

Why do not Photographic Portraits Always Look Like the Sitter?

The *Manufacturer and Builder* answers the question as follows: A very common cause is the improper illumination of the features while the picture is being taken. Different faces require different kinds of light to bring out the characteristic features, which are different in every individual; some require the light sideways, some more from above or below, others in front or more from behind; and if the photographer is a portrait painter, or at least an artist, he will know how to manage the light and illuminate the face of the sitter in such a way as to show the prominent characteristic features, and at the same time show the face to the greatest possible advantage. As a photograph consists of nothing but lights and shades, every phase of light and shadow as it falls on the face of the sitter is reproduced with the utmost fidelity.

In order to see the force of these remarks, one has only to look at the face of a person in the evening in a room lighted up by a single candle, and watch the changes in the appearance of the face when moving the candle, keeping it above the face, or at the side, or in front, or below. Unfortunately most photographers have no idea of all this, and have a fixed light—usually a skylight, which is indeed the worst to bring out any face to advantage; or they place every customer so as to face the light, and take his picture in front from the side where the light comes from; the result is a flat picture, without character, and having only a faint resemblance. There are many galleries where the lights can not be so managed as to give the kind of light needed for some countenances, and it is in such galleries that certain kinds of faces cannot be taken satisfactorily.

Most of the leading photographers have commenced to see the great advantage of being able to obtain the light also from the side, and even from below, and to be able to screen the top light with proper curtains; hence the really fine artistic pictures obtained nowadays by those photographers who, being artists themselves, are foremost in this beautiful art.

The Blast Furnace.

Engineers have at different times directed their attention to the obtaining of a metal which shall be so resistant of the action of partially molten iron as to prevent those accidents which now and again prove painfully disastrous in the working of blast furnaces. The smelting process should go gradually on, the iron steadily exuding, as it were, from the stone as the blast heat operates upon it. Sometimes the partially smelted materials hang, or "pocket," at a little distance above the tuyeres, and after a time come down with a rush. There is risk that during the fall particles of molten iron and cinder may impinge upon the tuyeres, burn them through, and allow the water to escape into the furnace, with the result that the heated mass coming down upon the water so escaped, an explosion ensues. By an accident of this class four furnace men were killed at the Hot Holes furnace, near Wolverhampton, not long since. The tuyere in this case was one of seven, and was made of a brand of boiler plate iron known in the locality for its excellence. With this iron the tuyeres are constructed by the blacksmith of the firm; and if, after doing duty in the furnace, they are found to have become worn they are not wholly cast aside, but are "nosed" with the same class of material. This tuyere had been nosed, and it had been at work some twelve hours before the explosion. Furnace managers tell us—and it was so contended at the inquest in the case—that it is impossible to prevent pocketing and the lodging of portions of incandescent stuff on one or other of the tuyeres. Assisted by the engineers they have, therefore, turned their attention to the obtaining of a material which shall not be eaten through by the hot metal. As we all know, mixed metal, bell metal, and copper have each been in their turn tried, and Mr. Hickman has tried them, with the result that he finds nothing safer than really good boiler-plate iron. If other people's experience has been different to this, we hope that for the benefit of those who have been less successful they will make it known.—*The Engineer.*

Keeping Piano-Keys White.—It is said that piano-keys will not turn yellow if exposed in a light room. Never close an instrument with ivory keys. Throw a sheet over when sweeping and dusting. Wet a soft cloth in alcohol and rub off all dirt, then expose as much as possible to the sunshine. If they are very yellow it will take a few weeks to restore the original whiteness. To facilitate the process, re-wet with alcohol once or twice, though they will whiten without in time.

Bees' Eyes.—The lenses of bees' eyes are not adjustable; and, though they can see accurately to great distances, they seem blind to objects close by. Bees dart down to the door of their hives with a precision which is generally unerring; but if, from any cause, they miss the opening, they are obliged to rise in the air in order to take another observation.—*Popular Science Monthly.*

Salt.—*Hall's Journal of Health* thus sums up some of the many uses of salt: "It will cure sick headache, make cream freeze, make the butter come, take ink stains out of cloth of any kind, kill worms, kill worms, make the ground cool; so it is more congenial to celery, cabbage, etc. It will ease the itching pain caused by irritating skin diseases, like hives, itch, etc. It will produce vomiting or stop it, as you like; and many other things too numerous to mention. All pure salt will do this to a certain degree, but sea salt is the most effectual in its action." Salt is a most remarkable and highly useful substance; but we think that our contemporary will find, on practical trial, that the article will not do all that is above claimed. For example, salt will not make cream freeze, it will not take ink stains out of cloth, and probably will not do more than one or two of the other things above mentioned.

Pencils have lately appeared, the writing of which is capable of being copied, more or less perfectly, in the press. They are said to be made of a mixture of graphite, kaolin, and blue violet aniline. The graphite is used in the form of a thick paste, the kaolin in a finely pulverized state, and the aniline in the form of a very concentrated aqueous solution. The whole when well mixed is molded under the press with cylinders about four inches long, and of the required diameter. Gum arabic may be substituted for the kaolin.

A Dangerous Poison.—A dangerous poison has recently been discovered to exist in the bamboo cane. The cavity at each joint contains a quantity of small black fibrous matter, covered with an almost imperceptible coating of tissues, which conceals the poison. If swallowed, the filaments do not pass into the stomach, but remain in the throat, producing violent inflammation, and finally death. Juvenile smokers of the cane ought, therefore, to be careful.

Handsome ornaments can be made by mounting fern leaves on glass. The leaves must first be dyed or colored. They are then arranged on the mirror according to fancy. A butterfly or two may be added. Then a sheet of clear glass of the same size is placed on top, and the two sheets secured together at the edges and placed in a frame.

It is not generally known that the Treasury Department employs two learned and skillful chemists, one of whom is constantly engaged in fabricating indelible inks, while the other devotes his talents to washing out the inks, and, thus far, chemistry has devised no ink which chemistry cannot efface.

Good Health.

Fat Men of Sparta.

Fat is not a sign of health. We like to see portly men, and some there are who can wear their two hundred and thirty pounds of bone and tissue handsomely. Yet you would not select such men for endurance, nor for the chase.

The ancient Spartans understood this thing. They paid as much attention to the rearing of men as our best stock-breeders of to-day pay to the rearing of fine horses. They took charge of the firmness and looseness of men's flesh, and regulated the degree of fatness to which it was lawful, in a free State, for any citizen to extend his body. Those who dared too grow too fat or too soft for military campaigning in the service of Sparta were soundly whipped, and if they would not, of their own accord, reduce their flesh, they were taken in hand by trainers, who, with spur and lash and corresponding diet, soon brought them to the required standard.

In one particular instance, that of Nauclis, the son of Polybus, the offender was brought before the Ephori, and a congregation of the chief men of Sparta, at which his unlawful fatness was publicly exposed in the market-place, and he was threatened with perpetual banishment if he did not bring his body within the regular Spartan compass, and give up his culpable mode of living, which was declared to be more worthy of an Ionian than a son of Lacedemon.

The Effect of Close Confinement.—In 1865, a young English actor named Walter Hastings, at a club meeting, made the remark that close confinement was not a very terrible punishment, upon which Lord S. offered him £10,000 if he would try it ten years. He accepted the offer, and retired from the stage to a dark cell fifteen by ten. He was allowed plenty of food, light, books, and writing materials. He has emerged from his prison, and is spending his hard earned coin in Paris, intending to return to the stage. He began his fool-hardy experiment at twenty-five, but left his dungeon looking like a man of three score.

"Milk, after it has been yielded by the animal, may suffer contamination at a later stage," says T. A. Franklin. A case is on record where the milking was performed by persons recovering from scarlatina, and the disease thus conveyed by the milk to children who drank it. Milk rapidly absorbs numerous offensive odors, is established beyond a doubt.

The Cerebral Arteries in Old Age.

A not uncommon condition of the arteries of the brain, especially at its base, is those far advanced in years, is the displacement in places of the middle coat by lime particles, which, of course, renders them easily torn. So far as known, this condition is incurable, as well as unpreventable. It is one of the changes of structure incident to very old age. The only measure that can be relied upon to prevent a rupture under such conditions is to be cautious about distending them with the blood. This is, in fact, the great fundamental principle of prevention, when the vessels of the brain are weak from any cause.

To effect this, certain regulations in eating and drinking are far better preventives than any medicine, or even occasional bleedings. The latter method is particularly unsafe. After bleeding from the arm, new blood is often made more rapidly than under other circumstances, and so may become, before a person is well aware of it, very abundant, with a dangerous pressure on the weak vessels. The subject of such a practice is very apt to rely on the abstraction of blood for safety, and take no care otherwise of himself. Besides, he has no accurate means of knowing when the pressure of the blood is becoming dangerously great. The periodical bleeding from piles is a very different matter. They often act as a safety-valve to the high pressure from within, and regulate themselves on mechanical principles. Full-blooded persons, past middle life, and with a predisposition to apoplexy, should never try to remove such a safety-valve.

As soon as old age puts a decided check on the amount of daily exercise, it is time to put a decided check on the food consumed. If the supply of new matter is greater than the waste of the old, an accumulation of surplus blood must be the result. The principle is an important one, yet it is little known and less practiced. Men well past middle life, who do not exercise half as much as in their younger years, often eat as highly nutritious food as they ever did. Such a course is very dangerous. The tension on the vascular system must not be increased, but diminished, if the risk of an apoplectic stroke would be avoided.—*Popular Science Monthly.*

Do Alcoholic Liquors Supply Bodily Heat?

Dr. Richardson, F. R. S., recently proved by careful and accurate experiments that alcohol lowers the temperature of the body, and increases the action of the heart, which is thus jaded and worn out before its time. "There was," Dr. Edward Smith said (at the British Association meeting at Bradford), "a certain sensation of heat in the stomach and in the skin, but there was no actual increase of heat; the increased quantity of blood sent into the blood vessels on the surface of the body gave more heat to those parts of the body, but the store of heat in the body was diminished." It is this heightened circulation and the propelling of the blood in larger quantities to the surface of the body, which gives the agreeable sensation of heat after a dram or other alcoholic dose; the sensation is real, but the cause of it is very different from that usually supposed. * * * We do not deny the pleasant sensations and apparent benefit which may be derived from alcohol, especially by those who have become accustomed to its use; but we maintain that these are delusive and dangerous, that they are not legitimately obtained, but procured at the expense of real and lasting evil. * * * You may say you have often felt better for a dose of alcohol; but your feeling deceives you, or rather, you draw an erroneous conclusion from it (as we have already shown in reference to the heat-giving power), and it is the province of science to correct this false impression.—*Smith's Prize Essay.*

The Blood Cure.—The practice which has recently come rapidly and widely in vogue of taking for consumption and some other diseases drafts of warm blood, the moment when extracted from the calf or ox, has gone into considerable disuse of late, on account of distaste, inconvenience and other reasons. Dr. De Pascale, of Nice, has successfully adopted a substitute in the form of dry powdered blood. The blood of the animal, after being dried in a water bath, is reduced to a very fine powder and grated through a sieve, and it can thus be taken for any length of time without repugnance, being almost tasteless; can be taken as any common powder, mixed with soups, milk, marmalade or chocolate, or inclosed in a wafer. Dr. Pascale has given it in some cases mixed with a little pepsin. The quantity of the powder he varies according to the patient's age, sex, state of health and digestive power; in general beginning with thirty grains, increasing as circumstances may dictate.

An Unhealthy House.—A dark house is always an ill-aired house, always a dirty house. Want of life stops growth and promotes scrofula, rickets, etc., among children. People lose their health in a dark house, and if they get ill, they cannot get well again in it. Three, out of many instances of negligence and ignorance in managing the health of houses, I will here mention as specimens. First, that the female head in charge of any building does not think it necessary to visit every hole and corner of it every day. Second, that it is not considered necessary to air, to sun and clean rooms while occupied. Third, that one window is considered enough to air a room.—*Florence Nightingale.*

Domestic Economy.

Recipes for Making Buckwheat Cakes.

One quart of buckwheat flour, a small teacupful of Indian meal, one and a half teaspoonfuls salt, four tablespoonfuls good lively yeast; mix with milk and tepid water enough to make it the consistency of muffin batter; then beat well for fifteen minutes, and set in a warm place to raise over night. In the morning the batter may be sour; if so, dissolve a teaspoonful of soda in a little warm water and stir in; if the cakes are not sweet add more saleratus; do not beat the batter; add a tablespoonful of molasses to brown the cakes—the milk does not always brown them sufficiently. Bake on a well heated griddle that is perfectly clean; a soapstone griddle needs no greasing; an iron griddle should be greased with a piece of rind of ham or fat salt pork on a fork. Butter and silver-drips syrup are best to eat with buckwheat cakes; maple syrup is also good.

Another.—Let the buckwheat be of the hulled sort, and fresh. Put into a two-quart pitcher one and a half pints of tepid water; add four tablespoonfuls of baker's or as much "compressed" yeast as will make one loaf of bread—other kinds in proportion—with a little salt. Then stir in buckwheat enough to make a thick batter; cover the pitcher and set away to rise over night, after beating thoroughly. In the morning add three tablespoons of molasses, and a quarter of a tablespoonful of soda, dissolved in about three tablespoons of milk. Beat all well together, and pour the cakes from the pitcher upon a well heated griddle.

Still Another.—Take one cupful of flour, two of buckwheat flour, and one of yeast; one tablespoonful of sugar, and salt according to taste. Mix with enough water to make a stiff batter, and set to rise over night. In the morning add water in sufficient quantity to make the batter run when poured on the griddle.

Recipe for Preserving Meat.

The following paper was recently read before the New York farmers' club: "There is no good reason why farmers and their families should eat so much salt pork, leaving all the fresh meat to the inhabitants of cities and villages, when the following method will keep meat fresh for weeks even in the warmest weather. I have tried it for years. As soon as the animal heat is out of the meat, slice it up ready for cooking. Prepare a large jar by scalding well with hot salt and water. Mix salt and pulverized saltpetre. Cover the bottom of the jar with a sprinkle of salt and pepper. Put down a layer of meat, sprinkle with salt and pepper the same as if it was just going to the table, and continue in this manner until the jar is full. Fold a cloth or towel and wet it in strong salt and water in which a little of the saltpetre is dissolved. Press the cloth closely over the meat and set it in a cool place. Be sure and press the cloth in tightly as each layer is removed, and your meat will keep for months. It is a good plan to let the meat lie over night, after it is sliced before packing. Then drain off all the blood that oozes from it. It will be necessary to change the cloth occasionally, or take it off and wash it first in cold water, then scald in salt and water as at first. In this way farmers can have fresh meat all the year round. I have kept beef that was killed the 12th of February till the 21st of June. Then I packed a large jar of veal in the same way during the dog-days, and it kept six weeks. This recipe alone is worth the price of any newspaper in the land."

To Make Boiled Custard.—Take a pint and a half of milk, twelve drops of almond flavoring, a bit of stick cinnamon, three ounces of loaf sugar. Beat up the eggs with their whites in a half pint of the milk. Rub two of the lumps of sugar on the rind of the lemon till they are quite yellow; then put in the whole of the sugar, the pint of milk and the cinnamon into a sauce-pan. Let the ingredients boil for five minutes; then throw the whole out to cool for a short time; then beat all up together with the beaten eggs; return it to the saucepan for a few minutes, stirring over a very slow fire till it thickens; then strain it through a fine tin strainer into a jug; put the almond flavoring into another jug, and keep pouring the custard out from one jug to the other till it is cold. If it should be inclined to turn to curd, which it will do if boiled too rapidly or over too fierce a fire, keep pouring it through the strainer into the jug; when cold pour it carefully into glasses. Over the top of the custards may be grated some very fine nutmeg, or some blanched almonds cut up into fine shavings. The above quantities will fill from twelve to fourteen custard glasses, according to the size of the glass.

Fried Cauliflower.—Pick out all the green leaves from a cauliflower and cut off the stalk close. Put it head downward into a saucepan full of boiling, salted water. Do not overboil it. Drain it on a sieve, pick it out into small sprigs, and place them in a deep dish with plenty of vinegar, whole pepper, salt and a few cloves. When they have laid about an hour in this, drain them, dip them in batter, and fry in hot lard to a golden color.

MINING AND SCIENTIFIC PRESS.

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, W. B. EWER, GEO. H. STRONG JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week.	1 month.	3 months.	1 year.
Per line.....	.25	.80	$2.00	$5.00
One-half inch.....	$1.00	3.00	7.50	24.00
One inch.....	1.50	4.00	12.00	40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.25; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the PRESS promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

San Francisco:

Saturday Morning, Dec. 18, 1875.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Formation of Geyser Mounds; The White Pine Bonanza; Legislative, 385. Government Tests of Iron and Steel; Steam Pumps at the Recent Mechanics' Institute Exhibition; Notices of Recent Patents, 392. Mining Company Investigations; Machinists' Tools; Montana Mining Notes; Our Home Industries—Wire Making, 393. Patents and Inventions; General News Items; Industrial Items, 396.

ILLUSTRATIONS.—Extinct Oblong Geysers; Carboniferous Limestone Sections of Extinct Geysers, 385. Twenty Inch Swing Lathes Made by Kidd Iron Works, 392.

MECHANICAL PROGRESS.—Utilizing Old Railroad Iron; A Six Cylinder Engine; The Oil Engine; Rolling Rail Blooms, 387.

SCIENTIFIC PROGRESS.—Progress of the Sciences; A New Reagent for Gold; Latent Heat of the Vapor of Petroleum; Relation Between Spectral Lines and Atomic Weights; A New Theory of the Nebulae, 387.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 388.

MINING SUMMARY from various counties in California and Nevada, 388, 389, 396.

USEFUL INFORMATION.—Why do not Photographic Portraits Always Look Like the Sitter; The Blast Furnace; Keeping Piano Keys White; Salt: A Dangerous Poison, 391.

GOOD HEALTH.—The Cerebral Arteries in Old Age; Fat Men of Sparta; The Blood Cure; The Effect of Close Confinement; Do Alcoholic Liquors Supply Bodily Heat, 391.

DOMESTIC ECONOMY.—Recipes for Making Buckwheat Cakes; Recipe for Preserving Meat; To Make Boiled Custard; Fried Cauliflower, 391.

MISCELLANEOUS.—McCloud River Salmon Fishery; School and Mineral Lands; State Lands and Agricultural Products; Pancake Coal Company; Making Boxes; Ale and Porter; Using the Raw Material to the Utmost; The Sumner Mine, 390; 394, 396.

CHARLES G. MEYER was found drowned in the bay this week. Deceased was one of the oldest mining experts and assayers on the Pacific coast. He came to California in 1849, on the first overland stage, and has been engaged in most of the principal mining explorations of the coast. He was well known in Virginia City and Washoe, and had been through all the mining districts of the Pacific coast, Mexico, and Central and South America. Recently he was in the employ of Senators Stewart and Jones, at Panamint. Deceased was 47 years of age, and unmarried. He was a native of Germany, where his parents reside. From the fact that he has lately seemed down-hearted, it is surmised that he committed suicide.

V FLUMES.—A correspondent asks how the V flumes, so frequently spoken of as being used in the mountains for transporting lumber, are made. Briefly, a V flume, for transporting lumber, is usually made by placing two thirty-inch boards together, in the shape of a V. Where water is scarce a ten-inch board is fastened in the bottom.

TESTS with a new explosive are being made at Nevada City, California, and it is stated that the tests are very satisfactory. A manufactory will be started in that town.

WHEN the Defiance furnace started up recently, in Coso district, a salute of 75 guns was fired, and the population all felt joyful.

OVER 25,000 bushels of charcoal were on hand when the Defiance furnace started up last week in Coso district, Inyo county.

TRENOR W. PARK, of Emma mine fame, has sued the New York *Tribune* for libel.

THE Europa mine, on the Comstock, has secured its United States patent.

Government Tests of Iron and Steel.

The need of accurate rules and formulas for the calculation of the strength of iron, steel and other metals as they are used in this country, has long been felt by engineers, architects, manufacturers and mechanics. No comprehensive series of tests have ever been made in the United States from which such formulas could be deduced.

The English, French, German and Swedish Governments have had their metals tested with more or less care, and the formulas used most generally in this country are those deducted from the experiments made by the British commission appointed to investigate the application of iron to railway structures.

These experiments were made over a quarter of a century ago upon metals differing from ours in many of their characteristics. Small samples were tested and rules established for the calculation of the strength of large pieces in actual use, by the assumption of analogies that may or may not hold. Since these rules were made so many new processes have been invented and employed in the manufacture of steel and iron, and the modes of working them and the forms in which they are employed have changed so much, that the rules applied in calculating the strength of the metals as they are now used, are at best but very rough approximations.

From the inaccuracy of these rules and our want of the precise knowledge which a thorough set of tests should afford, we are in danger, on the one hand, of making the parts of our structures too weak, involving, as in the case of bridges, a fearful risk of life, and on the other hand we are compelled to use excessive quantities of material to guard against the accidents that might result from our want of knowledge of the strength of our materials to resist the various strains to which they are subjected.

So varied and multiplied are the uses of iron and steel by the civilized nations, that their consumption affords a fair criterion of the enlightenment of a people. And every citizen becomes directly interested in the correct use of these invaluable materials.

No individual, company or State can undertake such a set of tests as our country requires—so vast is its extent and so varied and extensive are its deposits of the materials required for the production of iron and steel. There is no inquiry our Government could undertake, which, in its relation to the useful industries of the country, could prove more valuable and important than an exhaustive investigation of the qualities of our iron, steel and other metals. And such an investigation is indispensable, if we would acquaint ourselves and the world with the superior qualities of the iron and steel we produce, and learn for ourselves and teach others their correct use.

Appreciating the value and importance of a thorough set of tests of American metals, Congress, at its last session, appropriated $75,000 for the purpose of inaugurating them. A board has been appointed by the President to make the tests, consisting of Col. T. T. S. Laidley, U. S. Ordnance; General Q. A. Gillmore, U. S. Engineers; L. A. Beardslee, U. S. N.; David Smith, U. S. N.; General Wm. Sooy Smith, C. E.; A. L. Holley, C. E.; Prof. R. S. Thurston.

The board has contracted for a testing machine, which, it is thought, will be the most perfect one ever made for the purpose, but costing almost the entire sum of the appropriation made.

The board has appointed special committees to prosecute the various lines of investigation which it has laid out, the experiments have been commenced, and the aid of the scientific and practical men of the country has been asked by the board to make its investigations as thorough and useful as possible. Appropriations will have to be made by Congress from time to time to meet the expenses incurred by the board, and the attention of the entire country is asked to this most important work in the hope that it will meet with universal approval and such influential support that Congress will not hesitate to provide the means to carry forward to completion the work so well begun.

WOOD AT EUREKA.—The *Sentinel* thinks there is a probability that the completion of the Eureka and Palisade railroad will cheapen the cost of wood at that end of the line. There is a well wooded section down about Garden pass, and we understand that the railroad, in connection with other parties, intend starting a wood yard in this town. If so, we may rely on a material reduction in the price of fuel.

AT the Mill City, Nevada, foundry, over 6,000 pounds of shoes and dies were cast last week, for John C. Fall, of Unionville. The *Silver State* says, that a large crane for the purpose of raising heavy castings has been erected, and the foundry improved generally.

THE Reno *Journal* says, the news from the quicksilver mines continues favorable. Sinking is being vigorously prosecuted, and the ore grows better as depth is obtained.

THE Committee on Patents in Congress this session is composed of Wadleigh, (chairman), Windom, Dawes, Johnston and Kernen.

Steam Pumps at the Recent Mechanics' Institute Exhibition.

The committee appointed to examine articles exhibited and competing for premiums at the late Mechanics' fair in classes 6, 6a and 7, have submitted their report. These classes comprised hydraulic motors, pumps of all kinds, windmills and horse-powers. The amount of labor that fell to the lot of this committee is their excuse for the delay in presenting their report. They give the report of the articles exhibited in the usual way, making a separate report of the pumps tested. The special report of the competitive trial will soon be made public, when we shall publish such parts as are of general interest. For the present we extract from the general report of the committee all that relates to the steam pumps, showing what awards were made, as follows:

Catalogue No. 171. Bucket and plunger steam pump, exhibited by Parke & Lacy, and built by the Valley machine works. This, so far as we can judge, ought to be a very serviceable pump. It is well built, easy of access and tasteful in appearance. It deserves honorable mention.

No. 990. Prull's steam pump, exhibited by the Pacific iron works. In this pump the steam is applied directly to the water without any moving parts. It would be very suitable in a place where simplicity is more important than efficiency. It is neat in appearance.

No. 991. Centrifugal pump, exhibited by Parke & Lacy, the only pump of the class exhibited. This pump has a good reputation and the hand pump attached for priming is a very important improvement. We would recommend a diploma.

Nos. 992, 995 and 996. This is a fine display of pumps, both steam and hand, exhibited and manufactured by W. T. Garratt, of this city. One of the steam pumps will be noticed in our report on pump tests. The fine workmanship and substantial finish which characterized this exhibit deserve our commendation, and we would recommend a silver medal.

No. 997. Quicksilver pump, exhibited by Martin P. Boss, a new device for the purpose of pumping or distributing quicksilver to the reservoir pans in a quartz mill, and is proving itself of great value where it has been applied, reflecting credit on the inventor. We would recommend a silver medal.

No. 998. This is an exhibit of the various styles of Cameron pumps by Neylan & Young, one fitted with the Stoddart condenser, which is very simple and effective. These pumps are well known and enjoy a good reputation. We would recommend a diploma for the condenser.

No. 999. Pulsometer and Eureka pump, exhibited by Gillins & Sanford. We failed to discover any merit in this exhibit.

No. 1,000. Sluthour force and lift pump, exhibited by J. M. Keeler & Co. These are pumps of peculiar construction. The bucket simply oscillates on its axis in a cylinder. They are very simple; have six large valve openings; good for dirty water. There are many situations where these pumps would be very effective and give a high per cent. of duty for the force applied. We recommend a diploma.

No. 1005. Knowles' steam pump. Exhibited by A. L. Fish & Co. This pump is well and favorably known all over America. One of these pumps will be thoroughly described in the report on pump tests. We were much pleased with the double ram force pump for very high pressure. It is an excellent piece of work and well adapted for very heavy work. We recommend a diploma.

No. 1007. The Sau Francisco steam pump. Patented by W. C. Wilcox, and exhibited and manufactured by W. C. Wilcox & Co. This pump will be fully noticed in the report of pump tests and for reasons therein set forth we recommend a gold medal.

No. 1008. The Blake steam pumps. Exhibited by H. P. Gregory. This is an excellent exhibit of the various styles of this well known pump. A full description of this pump will also be given in the report on pump tests, and for reasons therein set forth we recommend a silver medal. Signed,

G. W. DICKIE.
J. S. DETRICK.

THE Humboldt mill and mining company, whose works were closed a part of the time for repairs, shipped from Winnemucca during the month of November $20,000 in bullion. The treasure shipments for the year 1875 from this place were as follows: Coin, $161,746; currency, $42,310.20; bullion, $89,694.30; dust, $1,448.

A FIRE, arising from the refuse coal cast away at the chutes near the wharf at Sehome (W. T.) has not been extinguished during the past fifteen years or more. On dark nights it burns brightly and serves as a beacon light for mariners entering Bellingham Bay.

THE French geographical society has elected Gen. A. A. Humphreys, Chief of Engineers, United States Army, a corresponding member.

ALL the mines at Seattle are in operation at present, and coal is being delivered lively.

THE coal mines of Wyoming are worked by Chinamen.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

PHOTOGRAPHIC EYE REST.—S. M. Williams, Virginia City, Nevada. In taking photographic and similar pictures, one of the most difficult things to be done is to preserve a natural expression to the eyes, and this difficulty arises from the fixed stare with which the person is obliged to look at some object while the picture is being taken. Mr. Williams' invention is a device for fixing the attention of a person who is sitting for a photographic or other picture, where it is necessary to look in one direction for a considerable time, and it consists of a stand or frame which has within it a moving picture or panorama. This panorama is made to pass over a limited opening, so that the sitter will have the eyes rested by a succession of new objects without being obliged to move his eyes from the spot. By this means a photographic eye rest is provided which by its motion will relieve the eye and give a better expression to the sitter.

IMPROVED GANG PLOW.—Frank A. Hill, San Leandro, Alameda county. This invention relates to certain improvements on the Eureka gang plow, patented Sept. 9th, 1869, by the same party. The present improvements relate, first, to an arrangement by which the pole can be shifted to either side, so as to give the plows more or less land as desired, and also, to provide for giving it any degree of elevation desired. This he accomplishes by attaching the pole to a journaled plate, so that its forward end can raise and lower freely, while its rear end is supported in a slot in an adjustable box, which can be shifted on the axle, thus permitting the pole to be directed to either side, or up or down, as desired. The second part relates to a device for elevating the plows out of the ground, so as to carry them high enough above the surface of the ground to avoid ordinary obstacles, such as stumps, rocks, etc., over which the plow may pass. This is accomplished in a very effectual and simple manner: the forward end of the plow beams are curved downward so that the attachment of the pole to their forward ends will be somewhat lower than the axle, thus causing the draft to keep the plows in the ground, a feature which will be appreciated by those accustomed to using the old style plow, which has a continual tendency to ride out of the ground. Mr. Hill also attaches a roller by flexible arms, so that it will roll upon the ground directly in front of the plows and thus break down any standing weeds or stubble, so that it will be completely turned over to the bottom of the furrows.

This plow is now being made by Baker & Hamilton, of San Francisco, in their factory, at San Leandro.

AUTOMATIC ROTARY CARBURETER.—Thos. A. Stombs, San Francisco, Cal. This invention relates to certain novelties in the construction of rotary carbureters, consisting principally in the use of an automatic rotary driver, in connection with a rotary air forcing mechanism, the fans of said driver being of peculiar construction. It also consists in the use of a very effective system of carbureting sheets within the air cylinder and an automatically operating check valve to regulate the supply of liquid in the machine. This device being entirely automatic, needs but little attention and is quite economical.

SLOTTED FRAMING SQUARE.—John H. McInnes, San Francisco. This invention relates to an improved tool for carpenters' use, which the inventor calls a slotted framing square. It consists in the combination of a square, having its sides slotted with an independent adjustable arm, which is also provided with a scale, and can be set to any point upon the two arms of the square. This tool is valuable for laying out stairs, giving the length of stringer or carriage, and serving also as a pitch board and pattern. It also gives the length and the head and foot cuts for any given angle of brace bridging, hip, common or false rafter, and at the same time indicates the length in feet and inches. It can be used in place of the ordinary trammel for laying out an ellipse, and it may also serve as a mortice and tenor gauge when desired.

GUARD STRAP FOR SHAFTS AND STRAP COUPLING.—James Weatherhead, San Jose, Santa Clara Co., Cal. It frequently happens when a person is driving a horse in a buggy or other vehicle, to which a horse is harnessed between two shafts, that one or both of the reins will get under or around the forward end of the shafts so as to prevent them from serving to hold or guide the horse, and thus many accidents to life and limb have occurred. This invention consists in providing a guard or fender, which will prevent the reins from getting thus entangled; and also in an improved strap fastening, by which the ends of the straps can be cheaply and conveniently attached to the ends of the shafts.

THE San Juan *Times* says that Thomas Findley's liabilities will approximate $300,000, and that his assets will not exceed $70,000.

Mining Company Investigations.

The era of investigations still continues, and the internal developments in the Woodville mine seem to have stirred up the stockholders of several other companies. The long-threatened suit on behalf of the stockholders of the Woodville Consolidated mining company has at last been commenced, and we understand that it is in the hands of persons who will push it with vigor and determination until they have vindicated their rights and exposed a tissue of what, it is alleged, are the most disgraceful frauds that have ever disgraced Californian enterprise. The suit has been brought by Marion J. McDonald against the Woodville Consolidated S. M. Co., John W. Pearson, Andrew Baird, Henry N. Chauncy, Wm. J. Smith and Edward Curtis. The document is very lengthy, comprising some eight pages of closely printed matter, embracing a history of the grievences of the stockholders who have been agitating the subject for the past few months. Pearson is charged with having realized by his transactions the sum of about $602,000, irrespective of what may be due by him to the company from the many assessments when a fair account is taken between himself as treasurer and the company. Plaintiff asserts that the present Directors (named as defendants) are acting in the interests of the Justice silver mining company, and will not take any measures toward compelling Pearson to account for the many acts of fraud allegod.

The mill transaction is explained thus: Pearson had a mill built for $13,000, and for which he charged the company $40,000. He caused the company to enter into a contract for the building of the mill, with Berry & Westfall, as contractors; but in reality he himself derived the profit of $27,000.

The levying of the assessment of November 4th, 1875, is next set forth in the complaint, and it is declared illegal. Plaintiff alleges that Pearson's 60,000 shares of stock were credited as having paid the assessment; that the certificate is marked "assessment paid," when in fact no such payment has been made.

And the plaintiff further says that within twenty days past he is informed and believes, and therefore charges the said Pearson, acting with the three Directors, and they acting under his direction, entered in to a corrupt agreement to procure and sell to certain person or persons representing and controlling a mining company called the Justice silver mining company 60,001 shares of the Woodville Consolidated silver mining company, at and for a price or sum of $8 per share in gold coin * * * the object of such purchase being to acquire the said Woodville mine for the said Justice company. Under these circumstances the compliant demands judgment, and prays as follows: That Pearson be compelled to account for his management of the affairs of the Woodville Consolidated, and that he refund the moneys alleged to have been tortnously and frsudulently acquirsd. Second, That an injunction issue restraining defendants or their agents from attempting to collect the assessment levied on November 4th, 1875, and from levying or attempting to levy another assessment. Third, That a receiver be appointed to take charge of the mine and properties of the corporation.

Another investigation is on the tapis with regard to the Succor mine. A circular about this mine is being circulated as "something in the interest of the stockholders." It makes the following representation of the company's affairs: The estimate of the president of the mine for a shaft of 500 feet, the sum of $500,000. The mine is composed of a 15-stamp mill, capacity of 25 tons each 24 hours; at $9 a ton, 26 days' work in the month, the receipts are $5,750. Expenses of 10 men, 90 cords of wood, water, wear and tear of material—total, $2,040, leaves a net profit per month of $3,710. In forty-eight months the net profit is $178,080. For the receipts of assessments in four years, $342,800. Several invoices of hullion, $18,000. Estimates of the receipts, $538,880. Expenses, for a shaft of 550 feet deep, the first 250 feet by contract, the sum is, at $75 per foot, timber, $17,500; by the company, 200 feet at $100 per foot, $20,000; 400 feet of drift at $25 per foot, $10,000; unexpected expenses, $30,000; in case of error, double the expenses, $77,500, which will give as the grand total of these expenses, $155,000; therefore, there must remain in pocket, or in safes, the sum of $403,880, and the publishers of the circular want to know where it is.

The Baltimore Consolidated stockholders are not easy either, for one of them writes to the *Chronicle*, and asks the management the following questions: First, Why have you not made an annual statement of the assessments collected and of the money spent in developing the mine during the last year previous to the annual election? Second, How have you spent the $300,000 collected during the year just past, while you have worked only eighteen men in the mine? Third, Is half of the expense of sinking the shaft charged to the American Flat mining company? Fourth, Has the American Flat company a half interest in the Baltimore shaft? Fifth, Have you purchased new and expensive machinery during the last year? Sixth, What was the amount of the indebtedness of the mine at the commencement of the year?

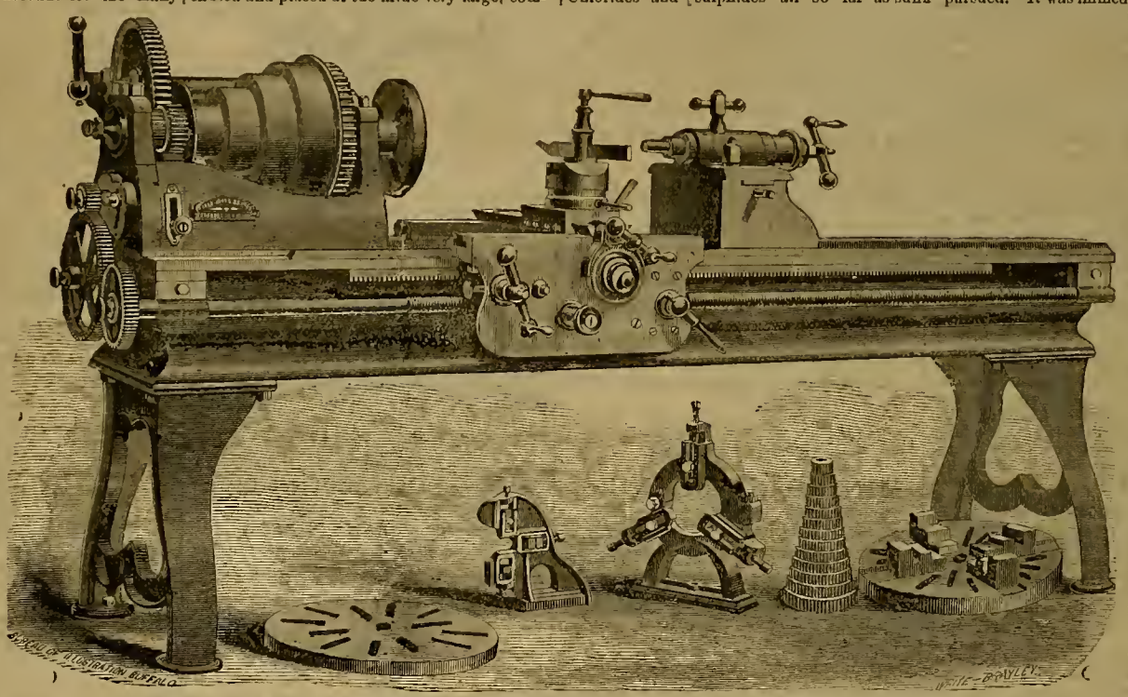
Mr. A. K. Grim, President of the company, says "Stockholder" should have inquired at the office, but nevertheless answers the above questions as follows: First—An annual statement was made, but I suppose "Stockholder" did not attend the annual meeting to hear it read. Second—It is not true that we have worked only eighteen men; the number has averaged seventy-six, and what was not expended for labor went for buildings, new machinery and the purchase of the shaft. Third—No part of the expense of sinking the shaft is charged to or paid by the American Flat mining company. Fourth—The American Flat mining company has no interest in the Baltimore shaft; it had at one time, but the interest was purchased by this company. Fifth—The company has purchased and placed at the mine very large, complete and expensive machinery during the last year; this accounts for a large portion of the moneys received during the past year, which, by the way, was $192,000, instead of $300,000. Sixth—The amount of the indebtedness at the beginning of the year was, in round numbers, $47,000. If "Stockholder," or any other stockholder, wishes further information, he or they will please call at the company's office, where they will have free access to the books, and will meet with prompt attention from a polite secretary.

We must confess that we are glad to see stockholders taking an active interest in their companies outside of stock transactions. It must result in benefit to all honest managements, and purify the moral atmosphere of other mining companies than those investigated. Keep it up.

In addition to the above, we see that the stockholders, representing 25,000 shares of the Gila silver mining company, have called a meeting to take measures to investigate the present management of the mine.

Machinists' Tools.

We illustrate on this page a twenty inch swing lathe, with an eight foot bed, such as is made by the Kidd iron works, Rochester, N. Y. The tools made by these works are of the latest patterns and very heavy. The spindles are very large and made of steel; the lead screws are also of steel and cut so as to make a perfect screw. The cones are extra large in diameter and broad in the face, the bearings long, the ways in the beds large, and the boxes are made of the best materials to prevent friction. The carriages are fitted so as to bore, turn and square with perfect accuracy. The lathes are furnished with Gleason's patent tool post, by which the tool can be elevated or lowered without loosening; it is also perfectly solid, and has the advantage of adjusting the tool without the double saddle, thereby enabling the machinist to swing a larger diameter over the carriage than by the old plan. The racks are all cut, and those on small lathes are of steel; the small apron gears are also of steel. In screw cutting it is necessary to change but one gear with each lead. The gears are nicely set and run without noise. The lathe shown has twenty inch swing and weighs 2,500 pounds. The bearings are 2¾ by 4½ inches, and the cone pulleys 12 inches in diameter by 2¾ face. The lead screws and rack are of steel.



TWENTY INCH SWING LATHES, MADE BY KIDD IRON WORKS.

Montana Mining Notes.

During the past year some very rich developments in silver have been made in Deer Lodge county, Montana, and mining interests there are looking up. A correspondent writes us that the operation of the Congressional law has stimulated prospecting, and at Butte City, where a year ago the population was confined to about forty men engaged in placer mining, there are now about 500 men engaged in sinking on leads in all directions. They have copper ores there which are now being worked at a depth of 125 feet, the ore being black oxide, assaying from 38 to 50¼ per cent. This is sacked and sent to Baltimore for reduction, being bought by parties in the business at very low figures from the miners, on the dumps, merely at copper rates, although the ore carries about forty ounces of silver to the ton. The silver ores are principally argentiferous galena. Chlorides and sulphides all so far as sunk are very free from base metals. A lot from two different lodes was lately worked at a mill about 100 miles from Butte City, and without roasting, worked by wet crushing, yielded, one lot $205 and the other $258 per ton. The leads are not very large as a rule, averaging from eighteen inches to six feet; they exist in a solid granite formation. All carry more or less gold, in some instances as high as $188 to the ton. Two mills are now in course of erection, one a private mill and one custom. The private mill will be ready for work about the New Year, the other not so soon. Every one there is well satisfied that they have a rich and lasting camp, and the town is steadily improving.

In this connection it may be well to mention an item to which the Helena *Independent* gives publicity. It states that it is whispered that several of the surveys in Colorado, Arizona and New Mexico, recently undertaken ostensibly for scientific purposes, are, in reality, designed to further the objects of a great land steal in the Territories where gold and silver is known to exist, Montana being included.

The *Independent* says: It has leaked out here that a big effort will be made, as soon as Congress meets, by a ring of land grabbers, to get hold of the most valuable mineral lands in Montana, Arizona and New Mexico. It is even broadly intimated that Hayden's and Jenney's surveys, ostensibly undertaken for scientific purposes, were in fact designed to further the purposes of the robbers.

Without pretending to know anything of the matter, we think it hardly probable that this is so. There are plenty of mines to be had all over the country; but capital is needed to work them. A gigantic scheme of the kind mentioned would be of little use. They couldn't take up mineral or agricultural land, and if they did they would have to give it up. We look upon the rumor as sensational.

The prizes awarded to exhibitors at the late Mechanics' Institute Fair, will be given to the owners, at the Mechanics' Institute, on Saturday evening, at 8 o'clock.

Our Home Industries.

Wire Drawing.

The undoubted value of every species of wire, its adaptability to hundreds of mechanical pursuits, has made its manufacture an essential and necessary adjunct of trade. The manufactnrs has been carried on in different ages on widely different plans; first, gold was beaten into thin plates and the wire cut out, then by hammering, until in the fourteenth century wire was drawn by hand. In a later century, in England, machinery augmented the manufacture and enabled the business to assume greater proportions. In this country wire drawing became an industry of more than secondary importance about the opening of the present century. The process of manufacture is carried on according to very simple plans, and yet in the prosecution of this work there is required a thorough knowledge of detail, an understanding of the business determined from years of practical application. Draw plates are made suitable for drawing wire of any required size. Copper, steel, iron, brass and zinc follow in the order of their ductility.

In this city, in common with those of the East, the manufacture of wire forms a valuable as well as interesting pursuit. It had its origin here in 1866, when Mr. J. Gray began the manufacture on similar plans as elsewhere pursued. It was immediately established as a permanent and necessary industry. The development of this business, however, was reserved for the Pacific wire and wire rope manufacturing company, an organized stock company of some five years' growth. The present prosperous condition of the trade augurs its future advancement and certifies to the exemplary manner in which the numerous duties have been discharged. Mr. J. B. Stetson, of the firm of Osgood & Stetson, is president, Mr. J. B. Bering acting in capacity of secretary, and Mr. J. Gray, founder of the business in this city, superintends the mechanical departments at the works on Brannan street. Mr. A. S. Hallidie is agent for the company.

The wire rods are imported from England in coils or bundles of about 150 feet in length, which weigh usually from eighteen to thirty pounds. There is a singular feature in connection with this trade, and that is the superiority of the American wire coils over the English brand and the general employment of the English wire on the score of economy, the cheapness of the latter affording better auspices for successful manufacture.

The Pacific wire company's manufacture consists of various sizes and kinds of wire, among which we may name annealed and bright market wire, baling, fencing, telegraph, coppered spring, homogeneous spring, pail, bale, charcoal, stone wire, etc. The productive daily capacity is one and a half tons, some sixteen men finding employment at wages of $2.75 and $3 per day. The rods of iron, steel, etc., are first pointed and drawn through the dies or plates some four or five times, every operation reducing the rod in size and necessarily adding to its length. It is then in fit condition to be annealed, and subjected to an acid bath to remove the scale or dirt, when it is transferred to tubs to be washed and secure a coating made from a composition of rye meal and flour, a process which enables the operators to draw the wire with a greater degree of celerity. Two long benches, which contain the necessary winders, plates, etc., range the sides of the buildings, the working machinery running the entire length of the building under the benches and communicating with the fixtures above. According to the required size of the wire is the annealing process carried on, the wire being subjected to the annealing ovens, which are capable in the aggregate of holding 6,000 pounds, sometimes as many as three and four times. The manufactured article ranges in size from three-eighths or one-half inch wire to that of a capillary-like nature.

The Vulcan company's coal mines, Santa Cruz county, about nine miles from the railroad at Watsonville, are being rapidly developed. They are said to have a vein of coal seven feet wide, and expect to ship coal by next June.

The Geddes & Buhard mine difficulties have been settled. The Eureka *Sentinel* says the furnace has been started up again and active operations have been resumed.

The Sumner Mine.

From an article on the Tulare mines we make the following extracts concerning the Sumner mine in Kern county: It appears that a new interest is now being awakened in the great mineral wealth of this county. The Snmner mining company is now doing a great deal of work. There are now in their employ 170 men. The eighty-stamp mill, which is the largest and most complete on the coast, is in constant operation, crushing from 100 to 120 tons per day. The mine is situated ahout three-fourths of a mile above the mill, and from the general appearance of the machinery, including the pump, hoisting works, etc, it is in every way first-class. By the kindness of the foreman we were conducted through the mine and shown the whole works. We entered the first level through a tunnel of about 300 yards in length, through which the ore is taken out, and the mine drained of the water. This is called the eighty-foot level, it heing eighty feet below the hoisting works.

A great quantity of ore has been taken from this level. From this point we descended eighty feet in the hoisting works to the 160-foot level. This level has been worked at a distance of 500 feet on the other side, embracing an entire length alonq the body of the ore of 1,000 feet, and msasuros wherever cut through from thirty to forty feet in thickuess; although the paying rock in some places appeara to run in strips or veius, and then again it widens out to the entire thickness. A depth of 200 feet has been reached, and the prospects continue to get better. The east casing of the quartz vein is clay, which is said to be a good indication of the depth of the rock. From the present prospects the rock of this mine is almost inex haustihle. At the mouth of the tunnel before spoken of is a large dump where the car from the mine is unloadod, and a chute from this opeus into a car that rnns to the mill. The road from the dump to the mill is laid with small iron railing, and the grade is sufficient so that the car runs with its own momentum, and is drawn hack by horse-power so that the coat of carrying the rock to the mill does not exceed $5 to the 100 tons. The rock enters the hnge dump at the mill, where it is deposited above the level of the building, and at an opening at the hottom of the dump the rock is taken out and passes through a rock breaker and then drops into a car which passes along the line of eighty stamps, and deposited into a hopper provided for each five stamps. From here it is thrown into the mortar hy a self-feeder, to he ground into powder. The whole works from the mine until the gold is extracted appear to he constructed on the most simple and economical plan. The quartz mill is run hy water, which appears to be very abundant at all seasons of the year. There is one difficulty attending the work in the mine, aud that is the great amount of watsr. It requires a pump with an eighteen inch pipe, making fifteen strokes per minnte, working continuously night and dsy, to keep the water out of the shaft. Several other shafts and tnnuela are being run on the same lead, and the erection of other mills and works are contemplated soon. Considerable work is heing done and the prospects are highly flattering on what are known as the Bull Run claims, five miles farther np the river.

THE PAYMASTER MINE.—This is one of a series of six mines owned hy the Martin White company, in Ward district, in this county. The company is composed almost entirely of San Francisco capitalists, who are doing the moat scientific miniug that has ever been done in that district. In this mine their ledge is from twenty-five to thirty feet in width, most of which is high grade ore, and we are informed that they uow have on their dump over 2,000 tons. The main shaft is down 165 feet, from which a great amount of drifting has heeu done. It is the intention of the company to thoroughly prospect the mine before either building a mill or furnace, for the reason that some of it is base, and some of it free milling ore. As soon as they arrive at a conclusion, which will he some time this winter, they in tend building two 30-ton furnacos or a large mill, which they propose to have ruuning as early in the spring as possible. The company have been shipping some of their ore to San Francisco, the proceeds from which has more than paid all the expenses of the mine. We do not know of any mining property in White Pine county that has so bright a future before it as the Martin White miniug company. There are a nnmher of other mines adjoining those of this company that are considered very valuable. Set Ward district down as a first-class mining camp in another year.—*Reese River Reveille.*

NEW FURNACE.—The new patent furnace of John Stonehar is nearly completed and will he ready for operation as soon as thoroughly dried. Its construction has been superintended by Mr. Creal, the patentee, who entertains the utmost confidence iu ita complete success. The result is of the greatest importance to the interests of this district, for if it will perform all that is claimed for it by the inveutor, it will entirely revolutionize the system of smelting in this viciuity, aud cause to he worked with profit a large number of mines producing low grade ore, which cauuot he worked at the present rates of reduction.—*Eureka Sentinel.*

NEW MINING DISTRICT.—Mr. C. H. Wheeler, superintendent of the Mohave silver mining company, and Mr. L. B. Cook, formerly of Bear valley, arrived in this city from the new city of Mohave. Mr. Wheeler reports the new mine as being very extensive, and containing rich gray carhonate ore in large quantities. He informs us that he has just received the plans for the furnace—sixty ton. There are already ahout one hnndred tons of ore out on the dump. Roads are being made, the miners having heen put to work on the roads to complete them before the machinery arrives, some of it being already shipped. The furnace will likely be sending in hullion in ninety daya. We are likely to have, from all acconnts, ono of the largeat and best base metal mines in the State. It has heen erroneously asserted tbat Messrs. Wessel, Whitlach and Irwin, mining experts who left here a few days since, visited this district. They visited Ord district but did have time to go and see the bonauza of the outh.—*San Bernardino Times.*

TO FILE A SQUARE CORNER.—The proper way to commence is, to do tho edges first, and he sure you form a straight line, both on the edge and the edgea or corners of the edge, on the oval or flat portion. This gives a starting point, and you will be able to go ahead without any trouble. If you commence in the right manner to file a piece of iron, the proper ways to finish your task will generally suggest themselves to you as yon go along, if you properly heed your work and try to do it well. Don't work toward the corner; if you do, the moro you file the less like a corner will it become. Work the reverse—from the corner. There is no difference, let it ho a dash, dash-rail, seat-rail, seat-handle, and angular hody loop, or what not, having a corner or angle, the same rule applies to all.—*Ex.*

EMPIRE PARLOR MATCHES

We have imported the requisite Machinery and Chemicals to add to our previous assortment of Matches the celebrated Parlor Match, deservedly popular among families and smokers, on account of brilliant hurning qualities, and a tsence of smell or odor. Manufactured from the best sugar pine, a wood Superior to any other, and found only upon the Pacifio Coast. They are full count, and without objection of any kind. Packed in boxes of most desirable style. Brimstone and Safety Matches of superior quality manufactured, and are guaranteed to give entire satisfaction. Encourage Home Industry, and get superior goods at less cost than the imported article.

Ask your Grocer for the EMPIRE PARLOR MATCHES, and he sure you get no others. For Sale hy all Grocers.

OF INTEREST TO
MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially *machinery for mechanical ore concentration*, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for snccessful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

F. MANSELL & CO.,
SIGN PAINTERS,
423 PINE STREET,
(Between Montgomery and Kearny.)

Persons engaged in the following business can have their Signs Painted at contract prices, for goods or articles in which they trade, viz:

Merchant Tailors,	Genta'Furnish'g G'ds,
Bootmakers,	Furniture Dealers,
Hatters,	Jewelers,
Hotela,	Piano Fortes,

Wine Merchants, Etc., Etc.

VIRGINIA CITY SUFFERERS' RELIEF FUND.

NOTICE.—All persons who wish to contribute money to the assistance of the sufferers by the late fire in Virginia City, will please make out their checks in the name of GEO. S. DODGE, Treasurer, and leave the same at Rooms 12 or 17, Hayward's Building, California street. Those sending cash will please forward to the same name and destination.

Several solicitors have heen appointed, who are provided with pass-books signed hy the President, Treasurer and Secretary. The Secretary will he daily in attendance from 9 A. M. to 3 P. M.

HON. J. P. JONES, President.
GEO. S. DODGE, Treasurer.
RICHARD WHEELER, Secretary.

NEW FRUIT DRIER
FOR THE CENTENNIAL.

A man of limited means has recently invented a New Fruit Drier, which he wishes to exhibit at the Centennial. It is adapted to either farm or factory purposes,

Dries all kinds of Fruit and Vegetables,

And makes the finest kind of Raisins, with less labor and less fuel than any other Drier ever invented. He wishes to dispose of an interest in it or take a partner who will furnish means to carry out his plan. This will afford some enterprising man a good opportunity to visit the Centennial, and make money at the same time hy selling the Patent. For particulars call on or address

TIFFANY & ROBERTS,

Also, Celebrated Amateur's Lathes, Tools and Fittings of every description. Intuitable Castings, for $1,00 per set and upwards, by means of which numbers of the above Steam Engines, Lathes, &c., have been successfully made by Amateurs. Thousands prove the unparalleled success of the above models and castings.

For full descriptions and prices of the above, together with the requisite tools, see "Parr's Technical Guide," 8vo., Eighth edition, Sixty-fifth thousand, over 150 pages with nearly 600 splendid illustrations, giving full instructions in Scroll or Fret Carving and Scroll Sawing, and 150 Parlor Experiments in Chemistry, the wonders of Microscopy, the beauties of model Telegraphy, together with other useful and scientific information; also, all necessary instructions how to buy, how to use, and how to make model engines. Post free, 30 cts. Address GEO. PARR, Manufr of Mechanics' Tools, BUFFALO, N. Y.

DUNHAM, CARRIGAN & CO., San Francisco, are Sole Agents in California for my Heavy Wood Working Machinery.

EDWIN HARRINGTON & SON,

Manufacturers of ENGINE LATHES, 48 inches swing and smaller; VERTICAL BORING MACHINES, suitable for jobbing and boring Car Wheels; UPRIGHT DRILLS, 36 inches and smaller, and other Machinists' Tools.

COR. NORTH FIFTEENTH ST.
AND PENNSYLVANIA AVENUE,
Philadelphia, Pennsylvania.

STEAM ENGINES & BOILERS

From 3 to 75-horse power. Shafting, Pulleys, Hoist Gears Quartz Mill, Water Tanks, Spanish Arastras, Pumps and Pipes, Hepburn and Belden Pans, and all kinds of Machinery for sale at lowest prices by

THOS. P. H. WHITELAW,
266 Brannan street, S. F

Highest cash prices paid for all kinds of Machinery.

WATTERSON'S

Improved Chisel.

The Improved Chisel here illustrated was recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency. The improvement is adapted to all CHISELS FOR MACHINE OR HAND USE. The improvement consists of a Chisel in two parts, as shown in the engraving.

For Machine Use

We use TWO STEMS. From one-fourth inch to one-half inch, use one-fourth inch stem. For all Chisels from one-half to one inch, use one-half inch stem.

For Hand Use

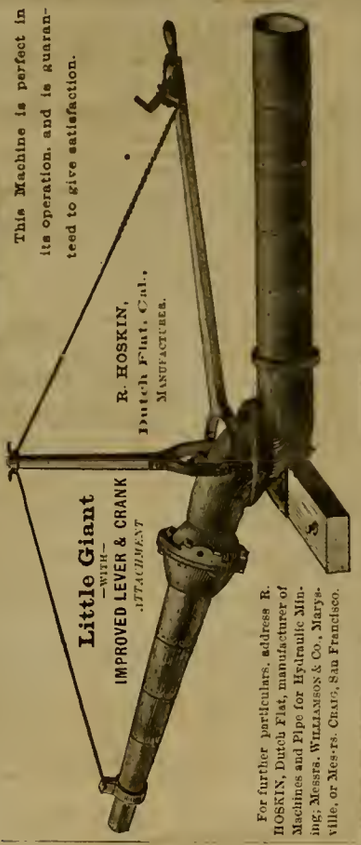
Use from THREE TO FOUR SOCKETS (or upper portion) for a set of Chisels.

For further information, address

ARTHUR R. WATTERSON,
No. 613 Mission Street,
SAN FRANCISCO, CAL.

MINERS write for your paper.

This Machine is perfect in its operation, and is guaranteed to give satisfaction.



For further particulars, address R. HOSKIN, Dutch Flat, manufacturer of Machines and Pipe for Hydraulic Mining; Messrs. WILLIAMSON & Co., Marysville, or Messrs. CRAIG, San Francisco.

DAVID WOERNER,

COOPER,

No. 104 and 112 Spear St., San Francisco.

Wine Casks, Tanks, Tubs, Pipes, Beer Barrels, etc., Manufactured at Short Notice and LOW RATES.

LUMBER for CASKS, etc., TANKS, etc. Steamed and Dried if required.

THE TURBINE.

Simplest, Cheapest, and Most Durable.

The Inventor of the Dexter Windmill has made new and useful improvements in Windmills, patented March 16th, 1875, and now feels confident of having the SIMPLEST, CHEAPEST, MOST DURABLE, and

ONLY PERMANENT WINDMILL IN THE WORLD.

SIMPLEST, because it is less complicated; CHEAPEST, because it never needs repair, standing on a firm foundation; MOST DURABLE, because it is all under cover, and has less rigging to get out of order; ONLY PERMANENT, because the only Windmill in the world that has never been injured by storms. Hundreds of people, who have thought the Dexter perfect, will be glad to observe the SUPERIORITY OF THE TURBINE over all predecessors. Although much improved, the price of mills remains the same as formerly. Persons who study their own interest will investigate the TURBINE before purchasing any other.

Territory for sale outside of California, at reasonable rates and easy terms.

Mills built to order of the best material, and at the shortest notice, by Kimball Manufacturing Company, corner Fourth and Bryant streets, San Francisco. Any orders sent to their address will receive prompt attention.

☞For further information regarding Mills or Territory, send for New Circular. Address,

CHAS. H. PHELPS,

ATTORNEY AT LAW,

306 PINE ST., N. W. Cor. Sansome, SAN FRANCISCO

☞Especial attention given to cases involving Mining, Patent or Commercial Law.

(Continued from Page 389.)

than ever, with an increased force of hands.

New York Consolidated.—Work goes ahead prosperously, as usual, at tha 800-ft level, the cross-cut progressing well and water not interfering. The material met with is of the most flattering and encoursging nature and a good paying ore vein is evidently not far off.

Kossuth.—The shaft is down 85 ft below the 500-ft level, and the sinking, which has been stopped in order to make some improvements in the machinery, will he resumed iu a very few days. An air shaft has been completed from the surface to the 200-ft level, at a point 600 ft south of the shaft, and a winze is now down 20 ft below the 200-ft level, at the point where the air shaft is sunk, which will connect with the south drift on the 350-ft level, and then he continued downward to ventilate the 500-ft level. The main sonth drift on the 200-ft level has been run south 1,300 ft from the Dayton company's line, the entire distance in fine quartz, and a good part in low grade ore. The west drift, on the 500-ft level, has reached the east wall of the ledge and must now soou cut the ore vein. Considerable trouble has been caused by the strong flow of water for some time past, but is now easily handled by the pumps, so that work can soon be again vigorously prosecuted on the 500-ft level.

Belcher.—Daily yield, 450 tons of ore. The ore breasts on the 1500-ft level are looking splendid and affording the usual amount of good ore. The proapecting drifts on the 1300 and 1400-ft levels are all in quartz of a fine character. The ore vein in the east ledge, on the 1200-ft level, is widening and opening out much hetter than haa ever been expected.

Globe Consolidaten.—Work at the 3d atation ia confined to driving the drifts on the course of the vein. In the aouth drift the ledge is 16 ft wide, the rock assaying from $7 to $15 per ton. The ledge running southwest ia in fine ledge msterial, giving an average of $20.50 per ton, with every indication of running into a paying chimney of ore. All that is wanted ia good pumping machinery for sinking deeper, in order to make the Globe first claas property, as the indioations and location are the most flattering. No change in the adit level in the south drift.

Chollar-Potosi.—Daily yield, 65 tons of ore, the assay value of which is $26 per ton. The main drift on the 1250-ft level is steadily advancing to the southward, the face in hard porphyry.

Leo.—Still driving ahead, and prospecting the ledge from the hottom of the winze 225 ft below the main tnnnel. The cross-cut is in 26 ft, hut has not yet reached the foot-wall; the face is still in favorable vein matter. The south drift is in 15 ft, also in a very promising character of ledge material.

Crown Point.—The nsual amount of ore is heing extracted and milled, the ore hreasts ahowing hut little change dnring the week. The main sonth prospecting drift, which ia being rnn west of the ora vein on the 1600-ft level, is being steadily pressed ahead to connect with the aouth winze, whioh is heing snnk below the 1500 ft level for air purposes. No cross-cutting of any consequence can he done on this level until this air connectiou is completed, as it is too hot for men to stand it to work even a very few feet away from the main drift. The south winze from the 1500-ft level, which is being sunk on an incline, is down a depth of 60 ft perpendioular, the hottom in good ore. The main esst drift on the 1700-ft level is being steadily advanced for the purpose of tspping and draining the ledge.

West Comstock.—This mine liea west of the Chollar and Bullion, and has been qnietly and systematically worked for aome time past, with what success may be jndged from the fact that the company have just declared a dividend of fifty cents per share, payable on the 21st. There are 1,500 feet in the mine, it pays its way and ia expected to prospect the heart of Mount Davidson, where no company has prospected yet. The company have disposed of 40,000 shares of their stock for a working capital, realizing $350,000; placing them on a very good financial basis, and out of the way of assesaments.

Oriqinal Gold Hill.—Daily yield. 25 tons per day from the south ore body. There are now about 600 tons of ore in the dump, and as soon aa milling facilities will jnstify, the amonut of ore extracted will he largely inoreased, there being plenty of it in the mine, The north drift is now being pushed ahead toward another good ore body known to exist in that direction.

Florida.—Owing to the ewelling of the ground, crushing in the timbers, and the amount of water met with, the main west drift at the 400-ft level haa not progressed quite ao fast as could he wished. Some splendid streaka of quartz, clay and other vein matter are now being passed through, and the indications are that the main ore vein ia not far distant.

Imperial-Empire.—Daily yield 50 tons of ore. Thia ore is extracted from the ore breasts on the 1930-ft level. The ore is not of quite so favorable a character as for some time past, the rich portions heing in streaks and spots, and the general average value lower.

Sierra Nevada.—The main west drift on the 1000-ft level is steadily advancing, the face in ledge material of a very favorable character.

Overman.—The main south drift on the 900-ft level is steadily advancing, the face in soft ledge material.

South Comstock.—The ledge material in the face of the cross-cut shows improvement, as it advances toward the main west ore veiu, which will he reached shortly, when hetter and more important developments are anticipated.

Succor.—The main north drift on the 550-ft level is steadily advancing. The cross-cut from the drift is in much softer material, interspersed with sesms of lively looking quartz.

North Cons. Virginia.—Sinking the shaft is going steadily ahead, the hottom in good fair sinking ground. Tha material in the bottom is porphyry, interspersed with seams of very favorable looking quartz.

Europa.—Sinking the main shaft is making splendid progress. It is now down 450 ft.

Gibbs.—This is an old '59 location, lying in Comstock canon, jnst east of Gold Hill, between the Europa and Sullivan mines. A tunnel was run into it by the first locators, in a northwesterly direction, following the west wall of the ledge abont 300 ft. At an eligihle point they attempted to cross-cut through the ledge, hut as soon as they got fairly through the west wall they tapped a heavy flow of water and had working grounds, which obliged them to quit work. Subseqnently a little work was done on it at times, as the ledge nssayed well wherever it could be prospected, hnt with the general decline of mining interests in this section, no aystematic development of the mine has been effected, nntil now it is getting into the hands of men of means and ahility, to open and work it properly, bringing out its true merits.

Prospect.—Main tunnel driving ahead in hard porphyry. It will soon pass through this into another ledge known to be a short distance ahead. The new hoisting works are about completed and will start into operation very shortly. The hoisting worka are excellent, and the huilding one of the hest in this section. The Prospect has a prosperous future before it.

West Belcher.—The tunnel is heing energetically pushed ahead toward the main ore body, which it will intersect in a few days.

Leviathan.—Face of the main north drift, at the 420-ft level, continnes in low grade ore. This will he followed for a while longer to ascertain the value of things in that direction, before any extensive development of the alrcady defined vein of good ore heretofore described.

Sullivan.—Tunnel still running in splendid looking vein matter, and nearly completed to a connection with the shaft. Water has been struck this week, and still more may he anticipated until the connection is made.

Dayton.—The new pump is lowered into position, ready to atart np. Everything in and about the mine is in fine working condition.

Cosmopolitan.—Low grade ore is met with at the varions prospecting points. The face of the main north drift, however, seems to be improving, giving better assays.

Nevada.—Drifting north in the middle of the ledge, toward the main ore chimney. Material in face of drift low grade ore with streaks of porphyry and olay.

Gould & Cuary.—Still pumping water from the 1700 ft level. The water will soon he sufficiently reduced to ngain resume work in that portion of the mine.

Silver Hill.—There is bnt little doing in the mine at present, except the sinking of the main incline, which is progressing at a favorahle rate.

Baltimore and American Flat.—Sinking the shaft ia making the usual favorable progress.

Savage—Still draining the water from the 2200-ft level preparatory to resuming the sinking of the main incline and south winze.

Caledonia.—Sinking the main shaft is making splendid progress, the rock in the hottom working much softer.

Best and Belcher.—Nothing yet doing on the 1700-ft level. The water is gradnally lessening so that work can be resumed at all points.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco.

New Albany M. Co.—Dec. 10. Location: Tuolumne county, California. Directors—Michael Castle, Fred. A. Benjamin, Judah Baker, Jr., I. Gratz Steinhart and John Stalker. Capital stock, $3,000,000.

Mariposa M. Co.—Dec. 10. Location—Spanish Belt mining district, Nye county, Nevada. Directors: M. San Pedro, Geo. F. Maynard, T. L. Kimball, Peter Van Felt and Murray Davis. Capital stock, $5,000,000.

Crœsus G. M. Co.—Dec. 10. Location: Amador county. Directors—W. Seawell, B. R. Zantzinger, J. M. Seawell, A. B. Paul snd M. M. Cuthbert. Capital stock, $5,000,000.

Loretta M. Co.—Dec. 11. Object: To do generally a mining and smelting business in the State of California. Directors—P. Reddy, G. H. Willard, W. G. Hughes, Jno. Wilson and Jno. A. Treaner. Capital stock, $10,000,000.

Ayres & Hopkins S. M. Co.—Dec. 14. Location: Eagle and Washoe mining districts, Ormsby county, Nevada. Directors—Joshua Q. Ayres, Henry Lacy, Geo. L. Woods, P. D. Barnhart and Wirt Hopkins. Capital stock, $10,000,000.

Ayres Cons. S. M. Co.—Dec. 14. Location: Eagle and Washoe mining districts, Ormsby county, Nevada. Directors—Joshua Q. Ayres, Henry Lacy, Geo. L. Woods, Wirt Hopkins and O. P. Willis. Capital stock, $10,000,000.

San Francisco Petroleum Co.—Dec. 15. Object: To contract and carry on the general business of prospecting for petroleum, naphtha, asphaltum and other mineral substances, containing or producing oil, and to extract, refine, reduce and work the same for market. To acquire all such roads, railroads, wharves, landings, etc., as may be needed. Directors—J. H. Mahoney, R. C. McPherson, Henry Abbott, Robert C. Page and Grove Adams. Capital stock, $10,000,000.

Valentine Patent Shingle Machine and Manufacturing Co.—Dec. 16. Object: Manufacturing and selling shingles, and also the Valentine machine for making shingles. Directors—W. P. Valentine, Edwin R. Ferris, J. F. Greenman, James E. Perkins and David O. Ferris. Capital stock, $5,000,000, in 50,000 shares of $100 each.

The Leopard mine shipped last week $4,200; the Justice $3,452; the Prussian $4,067.

General News Items.

Another China line of steamers is proposed.

Worth, the Parisian "man milliner," has failed.

More developments of the "crooked whisky business" in St. Louis are expected.

They are talking of onttings down the number of notaries.

An explosion of the steam heater at the Lick house in this city seriously scalded six men.

Our new Chief of Police, Ellis, has hegun his raid on the hoodlum element.

During the past eleven months our population has incressed 62,300.

Juan B. Alvarado, Governor of California from 1836 to 1842, is on a visit to this city.

The new woolen mill will be in operation at Vallejo in the course of a month.

E. W. Maslin has beeu appointed private secretary to Governor Irwin.

The Japanese man of war has arrived in our harbor, manned by Japanese.

They want the President of the United States to hold office for six years instead of four.

The talk is now of a Pacific coast Centennial celebration on a grand scale. A committee has heen appointed to initiate tha movement.

Indianapolis stands the best chance for the new mint. Where the hullion is coming from is not stated.

A State inspector of steam boilers is talked of, a hill now being before the Legislature creating the office.

The hill to prohihit a change of text books in the public schools passed both houses of the Legislature.

Our new Chief of Police is doing good work in clearing the corners of loungers and hoodlums.

Ex-Senator Nye has so far recovered his faculties as to he removed from the insane asylum.

Alameda is the second county in the State in the amount of its taxable property—$38,841,625.

The steamer *Los Angeles* was all right after all. She broke her machinery and was eight days under sail. Was taken in tow by the English gunboat *Rocket*, 20 miles from Victoria.

The courts have decided that the Panama railroad company have no right to establish a line of steamers from New York to Aspinwall, and from Aspinwall to San Francisco.

The Chinese factions in Virginia City have been having some pretty warm fights lately. Two wagon loads of shotguns were brought to Chinatown recently.

At Salt Lake, Utah, the jury in the case of George Reynolds, indicted for polygamy, under the act of Congress, found a verdict of guilty. Thia was regarded as a test case.

The "biography fiend" seems to have made a pretty good haul in this city writing up "Representative Men," and a good many gentlemen anxious for notoriety have had to pay well for it.

The "St. Louis land swindle" assumes large proportions. The estimates are that deeds to over 12,000,000 acres of land have heen forged and disposed of, at a total valuation of from $25,000,000 to $30,000,000. Mississippi and Arkansas seem to he the principal States that have suffered.

A. H. Southwick's turbine windmill and pumps were recommended a diploma at the Mechanics' Institute fair. The committee says: These windmills are gaining a wide reputation. They are very efficient motors and their design enables them to he treated architecturally, a point of great importance when they are used in private gardens.

The Sutro tunnel in November was advanced toward the Comstock lode 335 feet. This is an average of a fraction over eloven feet per day, and is not quite up to the average of last summer, hut some of the rock met with was unusually hard.

Fifty tons of iron ore from the mine near Latrobe has been sent down to San Francisco, to he shipped on the *Young America* for Baltimore, where it is to be used in the manufacture of Bessemer steel.

Denver sent East last week $23,170 in silver bricks — $1,609 from Golden, $2,570 from Georgetown, and $17,000 from Black Hawk. Shipments from the last place are made once a week.

The Mining Committee of Congress this session is composed of Sargent, (chairman), Hitchcock, Cragin, Howe, Hamilton, Dawes, Mitchell, Ransom, Kelley and Caperton.

Five thousand men have been thrown ont of employment hy the shutting down of some forty collieries in the vicinity of Pottsville, Penn.

Lester Coates was killed by a cave in the Williams claim, Prospect mountain, on the 7th inst.

The Belcher air shaft will connect in a few days with the npraise from the 1400-ft level.

They have a ghost in the North Star mine, at Austin.

Woodward's Gardens embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

Patents & Inventions.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

From Official Reports for the Mining and Scientific Press, Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

By Special Dispatch, Dated Washington, D. C., Dec. 21st, 1875.

For Week Ending December 7th, 1875.*

Gas Mixing Machine.—Lonis Lauszweert, S. F., Cal.

Thill Couplings.—Thomas McCaffery, S. F., Cal.

Combined Twine Cutter, Letter Opener and Stamp Moistener.—John Ettal, Sacramento, Cal.

Photographic Eye Rest.—Sylvester M. Williams, S. F., Cal.

Reissues.

Knitted Bags for Packages of Compressed Vegetable Substances.—James D. Culp, Gilroy, Cal.

Hydraulic Jacks.—Eneas M. Dudgeon, S. F., Cal.

Trademark.

Threshing Machines.—Knapp, Burrill & Co., Portland, Oregon.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of Issue.

Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Industrial Items.

The passenger cars for the railroad from Santa Monica to Los Angeles have arrived.

The railroad fare from Elko to Eureka has been reduced to $10.50.

Ordinary building lumber can now be had in Eureka for $65 per thousand.

Work upon the Denver and Rio Grande railroad is progressing rapidly.

The Los Angeles and Independence railroad will more than pay expenses during the first month of its running.

A wrought iron bridge is to be constructed across the Santa Rosa creek. A Topeka (Kansas) firm are the contractors.

The new water works for Virginia City will not be completed before June, 1876. The cost will be $130,000.

A cargo of ship spars are being delivered at Olympia for shipment direct to Newburyport, Massachusetts.

Steel rails are being put down on all the sharp curves of the Central Pacific railroad on the division between Carlin and Winnemucca.

The main canal to the Central California colony in Fresno county is completed, with the exception of one culvert yet to he completed.

The North Pacific railroad will he completed to Russian river by January 1st, if inclement weather does not forefend.

A telegraph cable is proposed from Vancouver island across the Gulf of Georgia to the mainland, by way of Burrard inlet and Nanaimo.

The work of fitting out cruisers and generally strengthening the navy is reported actively but quietly progressing at the Brooklyn navy yards.

Large supplies of lumber continue to arrive at Virginia City. The snow is not yet deep enough in the hills to prevent the lumberers from working.

The People's ice company at Truckee has a storage capacity of 15,000 tons. It has also two reservoirs which are filled with water from the mountain springs. One of these reservoirs covers an area of ten acres.

Duncan's mill, at the month of Russian river, closed down on the 8th inst. for the season. They have had a successful run of eleven months, during which time they have lost hut six days, two of them legal holidays. They have ont 7,000,000 feet of lumber, and have shipped 6,000,000, and have at their shipping point 1,000,000 feet.

Renew Your Subscriptions.—With encouraging rains, good mining prospects, a rapidly increasing population, public improvements and new manufacturing and industrial enterprises springing up throughout the coast, we believe the ensning year will he one of snch progress and importance that no snbscriber of the Press can afford to miss the record of events and discoveries which will be reported in the successive issues of this journal.

The world does not contain a medicine that will cure a distressing and dangerous cough or cold as rapidly and as certainly as Hale's Honey of Horehound and Tar.

Pike's Toothache Drops cure in one minute.

Sacramento, May 29th, 1875.

Messrs. Dewey & Co.—*Gentlemen:*

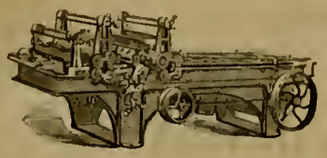
Yours of the 27th inst. is received. The patent came duly to hand yesterday, by express. Please accept thanks for your promptness in obtaining the same.

Very respectfully, Duncan Beaumont.

California Planers and Matchers, and Wood Working Machinery of all Kinds

California Planer and Matcher

Is gotten up from new patterns specially for this Coast. It has Cast Steel Slotted Cylinder Head, running in patent self-oiling boxes; will plane 24 inch wide and *six inch thick*, and tongue and groove 14 inch wide. Will make rustic and stick gutters, or heavy mouldings, etc., and is the best job machine ever built. ☞We have always on hand these machines with or without under cutter head, also, a large assortment of Planing Mill Machinery.



SMITH'S PATENT POWER MORTISERS, WITH LATE IMPORTANT IMPROVEMENTS.

Mortiser.

Smith's Celebrated Molders.

We have four sizes of these Machines always on hand—"B," "C," "D" and "E,"—to work either three or four sides. Have slotted heads and all other improvements, and may be seen in any mill on the Coast. ☞*Prices reduced* to 75 per cent. less than Eastern list. We have also, a large stock of all kinds of Planing Mill Machinery, such as Molders, Matchers, Tenoners, Band and Jig Saws, etc. Send for our new Illustrated Catalogue. TREADWELL & CO,

Smith's Celebrated Moulders.

Patent

TREADWELL & CO., - - - MACHINERY DEPOT: Market, Head of Front Street, - - - - San Francisco.

Mining and Other Companies.

Lake Mining Company—Location of

principal place of business, San Francisco, California. Location of mine and works, Quicksilver Mining District, Napa County, California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 4) levied on the third day of November, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
J H Goodman	25	2	$40 00
J H Goodman	31	10	200 00
P Christianson	35	10	200 00
James Lefferts	*unknown	8	160 00

*All the Company's records having been burned.

And in accordance with law, and an order of the Board of Directors, made on the third day of November, 1875, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the Company, No. 19 First street, San Francisco, Cal., on Monday, the twenty-seventh day of December, 1875, at the hour of 3 o'clock P. M., of said day, to pay the delinquent assessment thereon, together with cost of advertising and expenses of sale.

R. F. KNOX, Secretary.

Office, 10 and 21 First street, San Francisco, Cal.

Mariposa Land and Mining Company of

California. Location of principal place of business, San Francisco, Cal. Location of works, Mariposa County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the thirteenth day of November, 1875 an assessment, (No. 2) of one dollar per share was levied upon the capital stock of the corporation, payable immediately, in United States currency, to the Secretary, at the office of the company, room 33, Nevada Block, No. 309 Montgomery street, San Francisco, Cal., or to the Assistant Secretary, at the office, No. 9 Nassau street, New York City, N. Y.

Any stock upon which this assessment shall remain unpaid on the thirty-first day of December, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the first day of February, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

LEANDER LEAVITT, Secretary.

Office, Room 33, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

Owyhee Water and Gravel Mining Com-

pany. Location of principal place of business, San Francisco, Cal. Location of mines, Elko County, Nev.

NOTICE.—There are delinquent upon the following described stock, on account of assessment, (No. 1) levied on the first day of November, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

And in accordance with law, and an order of the Board of Directors, made on the ninth day of November, 1875, so many shares of each parcel of snob stock as may be necessary, will be sold at public auction at the office of the company, room 1, No. 402 Montgomery street, San Francisco, Cal., on Thursday, the sixth day of January, 1876, at the hour of one o'clock, P. M., of such day, to pay delinquent assessments thereon, together with costs of advertising and expenses of sale.

W. F. BOGART, Secretary.

Office, Room 1, No. 402 Montgomery street, San Francisco, California.

Peytona Gold and Silver Mining Com-

pany. Location of works, Virginia District, Storey county, Nevada.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. ——) levied on the 23d day of October, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Jacob Mayer	42	25	125 00
Jacob Mayer	41	10	50 00
Levi Strauss	121	5	25 00
C. V. Hobart	154	5	25 00
Wm. Doolan	105	033	4,665 00
T J Owens	203	15	75 00

And in accordance with law, and an order of the Board of Trustees, made on the 23d day of October, 1875, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of the Company, room No. 11, 215 Sansome street, San Francisco, on the 18th day of December, 1875, at the hour of 12 o'clock, M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

T. J. OWENS, Secretary.

Office, Room No. 11, 215 Sansome street, San Francisco, Cal.

Pioneer Fluming Company—Location of

principal place of business, San Francisco, Cal. Location of works, Shirt-tail Canon, Placer County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the thirtieth day of November, 1875, an assessment of five cents ($.05) per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at 116 Leidesdorff street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the third day of January, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the seventeenth day of January, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

W. AUG. KNAPP, Secretary.

Office, 116 Leidesdorff street, San Francisco, Cal.

Taylor Mill and Mining Company—Lo-

cation of property, Garden Valley Mining District, Et Dorado County, State of California. Principal place of business, San Francisco, State of California.

Notice is hereby given, that at a meeting of the Board of Directors of said company, held on the ninth day of December, 1875, an assessment of sixty-five cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, 607 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the nineteenth day of January, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the ninth day of February, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. SAMUEL S. MURFEY, Secretary.

Office, 607 Montgomery street, San Francisco, Cal.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufactnrers havo been compelled to add largely to their works—a new gas furnace and heavior trip hammer—and ara thus enabled to reduce the cost of steel and at tha same time produce SHOES AND DIES superior to any yet manufactnred. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find thom at least 10 per cent. cheaper than the best iron. There aro no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried thom pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron ara cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Torms liberal.

Address all orders, with dimensions, to W. R. Townsend, Secretary.

54 BUSHELS OF CORN AN HOUR.

HARRISON'S LIGHT, VERTICAL BURR MILLS

BARKER & BACON, MILLERS AND LUMBER DEALERS, SOUTH VERNON, VT., write July 15th:

"We have been running two of your LIGHT VERTICAL CORN MILLS for the past 6 months with remarkable results, and have ground over 80,000 bushels of corn into No. 1 meal in that time, running the grist-mill nights only, as we run our saw-mill in the day time. We have often ground in the 20-inch Mill (which weighs about 500 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 24,300 lbs., or 434 bushels. To do this we have to run at a speed of 1,300 turns per minute, and use about a 2½ horse power. You may refer parties to us for further information, and when we have tested your HEAVY VERTICAL MILL, we shall take great pleasure in giving the results."

Important in regard to Pumps.

Aurora, Nevada, November 10, 1875.

H. P. Gregory & Co., San Francisco.

Gentlemen: I am exceedingly well pleased with the "SPECIAL PATTERN BLAKE MINING PUMP" and its workings; especially so with the "MORTON EJECTOR CONDENSER." Have both in position on 400 foot level. The condenser is doing all that is recommended, and is saving from one and one-half (1 1-2) to one and three-quarters (1 3-4) cords of wood per day, I consider it a very useful improvement.

Yours Respectfully,

Warren Rose, Supt. Juniata Cons. S. M. Co.

We are prepared to put in the "BLAKE IMPROVED STEAM PUMP" in connection with the "MORTON EJECTOR CONDENSER" and fully guarantee a saving of from thirty to forty per cent. over any other direct acting Steam Pump in use.

At a Stated Term of the Circuit Court of the United States of America of the Ninth Judicial Circuit in and for the District of California, held at the court room in the city and county of San Francisco, on Thursday, the 30th day of September, in the year of our Lord one thousand eight hundred and seventy-five. Present—The Honorable Lorenzo Sawyer, Judge.

Nicholas Seibert, complainant, vs. Wm. T. Garratt, defendant—In equity.

DECREE.

This cause came in to be heard at the February Term, A. D. 1875, of this Court and was argued by counsel and thereupon upon consideration thereof, it was ordered, adjudged and decreed, as follows, viz: That defendant, William T. Garratt, was not the first or original inventor, or discoverer of the improvement or discovery claimed by him, in and by those certain reissued letters patent of the United States, number five thousand three hundred and twenty-eight (No. 5328), for an alleged new and useful improvement in lubricators, issued to said defendant, William T. Garratt, on the 18th day of March, A. D. 1873, and is not entitled to a patent therefor, and that said reissued letters patent, number five thousand three hundred and twenty-eight (No. 5328) are declared void and the same are hereby vacated and set aside by reason of their interference with those certain letters patent of the United States, number one hundred and eleven thousand eight hundred and eighty-one (No. 111,881) for a new and useful improvement in lubricators, issued to complainant, Nicholas Seibert, on the fourteenth (14th) day of February, A. D. 1871.

It was also further ordered, adjudged and decreed that complainant do have and recover of and from defendant his costs and expenses to be taxed herein.

(Signed) LORENZO SAWYER,
Circuit Judge.

The above decree has reference to "Seibert's Eureka Lubricator" for oiling the valves and cylinders of steam engines.

It has a glass gauge and condensing pipe, or reservoir, with a regulating feed valve, and works as follows: As the water of condensation is admitted, under the oil, just so fast the oil passes out at the top through a pipe into the steam pipe to oil the valves and cylinder.

Parties who infringe or purchase the infringed lubricators, will be held strictly responsible.

BY DEWEY & CO., Patent Solicitors.

SAN FRANCISCO, SATURDAY, DECEMBER 25, 1875.

VOLUME XXXI Number 26.

Apparatus for Producing a Blast or Vacuum in Laboratories.

No laboratory is complete without some appliance by means of which a strong and continuous blast of air can be produced. Since the introduction of "Bunsen's filter pump," the chemist can hardly dispense with some form of apparatus to produce a partial vacuum. In most laboratories different and distinct apparatus is used for each purpose, more or less complicated according to the means or requirements of the chemist.

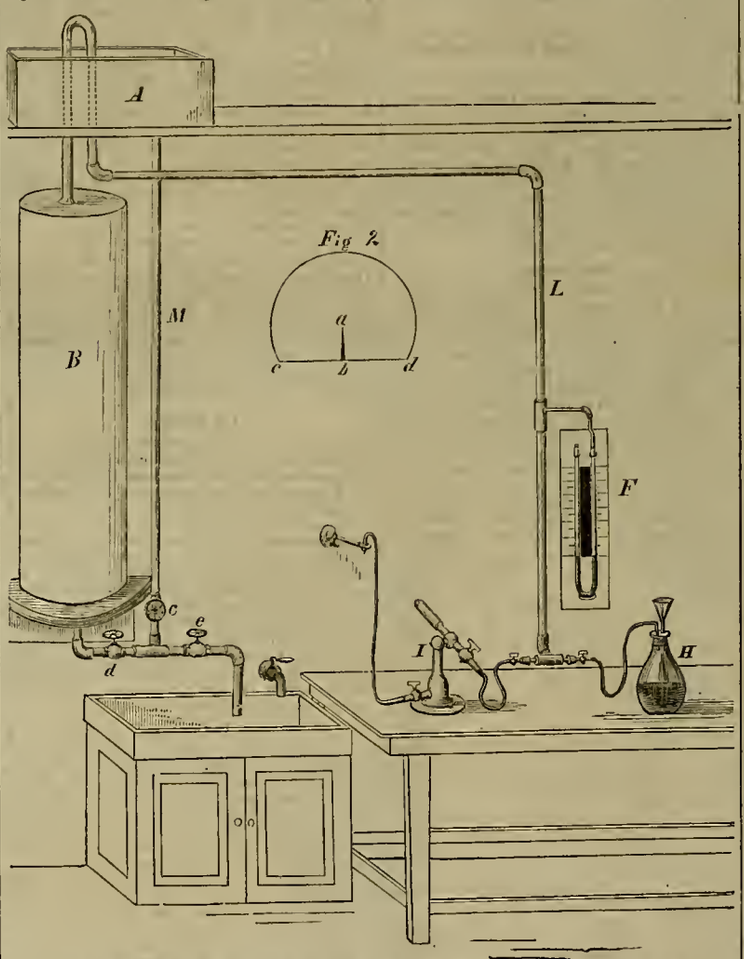
The apparatus contrived by Mr. Henry G. Hanks, of this city, and which he is using successfully in his laboratory, will produce either a blast or vacuum at will; the details are well shown in the engraving.

The tank, *A*, may be placed in any convenient position at about ten feet above the bottom of the galvanized iron cylinder, *B*, into which water can freely flow through the half-inch iron pipe, *M*. The tank is supplied with water by a ball cock not shown in the engraving. The diameter of the cylinder is ten inches, and its hight between five and six feet.

When it is required to produce a blast of air, the globe valves, *C* and *D*, are opened, and *E* closed. As the water enters the cylinder from below and rises gradually, the air is compressed and the rising mercury in the left hand portion of the U tube manometer, *F*, indicates the amount of pressure. When the mercury has risen one inch, the pillow cock is opened, allowing the compressed air to pass into the blast blow-pipe, *I*, the gas from the burner having previously been lighted. A powerful blue flame is produced, suitable for the requirements of the chemist's laboratory, or for soldering at the work table of the mechanic. The tube, *L*, must be carried above the tank, as shown in the engraving, to prevent the passage of water into the air tubes; as the pressure increases in the cylinder, the air must be graduated by turning the pillow cock. There will soon be a point reached, where the resistance of the compressed air will balance the weight of the water, when the mercury will rise no higher; with this Mr. Hanks can, when there is a pressure of nearly five inches of mercury, so control the air as to produce a clear blue pencil of flame three inches long, exactly suited for blow-pipe work, or for showing the colored flames characteristic of certain elements and salts. In an instant this can be changed to a roaring intensely hot flame from five to ten inches long, suited for bending large glass tubes, or for maintaining a white heat in a platinum crucible when fusions or incinerations are desired. The decomposition of chromic iron, or fusion of silicates with alkaline carbonates are easily made with this apparatus. To reverse this apparatus and to produce a partial vacuum, it is only necessary to allow the cylinder to partially fill with water and then to close the globe valve, *C*, the valve, *E*, being closed while the cylinder is filling. The compressed air is then allowed to escape, which will bring the mercury level in the U tube. The globe valve, *E*, is then opened and the water allowed to run into the sink; the mercury will now be seen to rise in the right hand manometer tube. When the mercury indicates one inch, the apparatus is in the proper condition to exhaust the air in the Bunsen filter bottle, *H*, by means of which the operations of filtering and washing the precipitates may be greatly accelerated.

The apparatus may also be used as an asperator, often of great use in the laboratory. The following example is given for those who are not familiar with such appliances:

Let it be required to dry some substance at the temperature of boiling water and to determine the amount of moisture removed. A glass tube is prepared of about half an inch internal diameter and about six inches long. Into each end is fitted a good cork, through each of which a small glass tube passes, and is allowed to project outward an inch or more. A weighed portion of the substance to be dried is carefully introduced into the tube by removing one of the corks, which is then replaced and the tube and contents weighed on a delicate balance. The tube is then connected with the apparatus by disconnecting the filter bottle, *H*, and slipping the end of the rubber tube over the glass tube projecting from one of the corks. The other end of the glass tube is then connected (also by means of rubber tubes) with two U tubes, one of which—the outer one—is filled with fragments of pumice stone previously soaked in concentrated sulphuric acid. The other U tube is placed in a beaker of water, which is heated to boiling by a gas-burner or spirit lamp. The pillow cock, connecting with the apparatus, is thus opened, and the air is drawn through, first the tube containing the pumice stone, any moisture being retained by the sulphuric acid; thence through the tube which is surrounded by boiling water, where its temperature is raised to



DEVICE FOR PRODUCING BLAST OR VACUUM IN LABORATORIES.

that of the water; thence passing hot and dry over the powdered substance, from which it soon removes the last trace of moisture. When this is known to be the case the glass tube is disconnected and weighed; the loss is the moisture.

As many persons are not familiar with Bunsen's filter apparatus, we will describe that portion which Mr. Hanks uses, and which is shown in *Fig.* 1, *H*. It will first be necessary to find a glass funnel, the sides of which form an angle of 60°. This can only be done by making a pattern and selecting by trial from a quantity of funnels. The pattern is made by drawing a circle of any convenient size and then dividing the circumference into six equal parts, drawing lines from the points to the center; this will divide the circle into six sections, each of which forms an angle of 60°; one of these cut from thick pasteboard will form the pattern required.

Having found a funnel of the proper shape, which should have a rather long neck, make a filter of thick writing paper. This is done by folding the paper twice and then cutting off the corners, so that when unfolded it will be a circle with two folds through the center at right angles with each other; upon being refolded and placed in the funnel properly it can be made to fit the sides closely, forming a perfect hollow cone.

A mixture of plaster of paris and water, rather thick, may then be prepared and poured into the paper filter while still in the funnel. When the plaster has *set* it may be removed and dried at a temperature below that of boiling water. If a piece of platinum foil, of exactly the size and shape of Fig. 2, is cut out with a pair of scissors, not forgetting to cut through from *b* to *a* at the same time, there will be no difficulty in bending it on the point of the plaster cast, into a small hollow platinum cone. This is to be placed in the funnel to support the points of future filters which would otherwise be broken by the pressure of the atmosphere.

It will be necessary to select a rather wide mouthed bottle, shown in *H*, Fig. 1. The funnel must fit tightly the perforated India rubber cork, the neck being allowed to enter the bottle some distance. The glass tube connecting with the apparatus does not extend below the under surface of the cork.

Before using, the bottle must be perfectly clean. The cylinder, *B*, having been allowed to fill or partly fill, the cock, *C*, is then closed. *D* and *E* being left open. Pour the substance to be filtered into a clean paper filter, placed in the funnel and supported by the platinum cone.

When the mercury indicates one inch, open the pillow cock and the filtration will proceed rapidly, the last drop passing through as quickly as the first. If the filtrate is to be saved, the cock may be removed, when all has passed through and the liquid poured from the bottle. If the filter contains a precipitate to be washed, distilled water may be poured into the funnel again and again until all soluble matter is removed.

Where there is no gas, the blowing apparatus may connect with a movable blow pipe and the flame may be produced by burning alcohol, oil, coal oil or a mixture of turpentine and alcohol.

In localities remote from business centers, where it might be difficult to procure the sheet iron cylinder, two tight barrels may be substituted for the tank and cylinder, so that a few iron pipes and fittings only are required to construct the apparatus, which will be found very useful and almost indispensable in the laboratories of mining companies. One of the great advantages of Mr. Hanks' apparatus is its economy in the use of water; the ordinary operations for what it is required may be conducted with the expenditure of only a few buckets of that fluid.

Academy of Sciences.

A regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening last, Vice-President Edwards in the Chair. A number of donations to the museum were received.

Mr. Edwards read a paper on the *Darlingtonia Californica*, a species of pitcher plant found in many places on this coast, and notably among the foothills of the Sierra Nevada and around Mount Shasta. It is found in mountain meadows and around bogs, often at an altitude of 5,000 feet above the sea. Mr. Edwards exhibited a number of specimens of the plant.

Vice-President Gibbons spoke of this plant, and its reputed property of digesting like animals, and thought most scientific men were now agreed that it has been demonstrated that the leaves do not possess actual digestive powers. For one, he does not believe they do, but thinks they reduce their food to a state of manure, which is then absorbed by its leaves, instead, as in other plants, by its roots. Some species of this plant, formerly used in the treatment of cases of small-pox, have been proven to have no such potency as was ascribed to them, and the practice is now obsolete.

The following ticket was presented by the Nominating Committee and adopted by the academy as the regular nomination for the ensuing year: President, Prof. Geo. Davidson; Vice-President, Harry Edwards; Second Vice-President, H. W. Harkness, M. D.; Corresponding Secretary, Theodore A. Blake; Recording Secretary, Charles G. Yale, of the MINING AND SCIENTIFIC PRESS; Treasurer, Edward F. Hall, Jr.; Librarian, Wm. J. Fisher; Director of Museum, W. G. W. Harford. Trustees: General David D. Colton, Robert E. C. Stearns, Wm. Ashburner, Thomas P. Madden, Col. George E. Gray, Ralph C. Harrison, General John F. Miller. The draft of a memorial to the California Legislature, published elsewhere, asking for appropriations for the continuance of the State geological survey, was presented by Mr. Scupham and ordered transmitted to the Secretary of State at Sacramento.

The following members were then chosen to act on election day as Judges of Election: Charles D. Gibbee and J. T. Lowry; and as Inspectors, Captain Richard S. Floyd and Samual Hubbard.

ALASKA, with its area of 570,000 square miles, will, if annexed to Washington Territory, make a very respectable sized county—about as large as Oregon, California, Arizona and New Mexico combined. With this addition, the Territory of Washington will have an area of 640,000 square miles.

THE Pico oil springs at San Fernando, down 70 feet, has struck flowing oil, and is yielding 30 barrels of oil a day.

McCloud River Salmon Fishery.

Work Done by U. S. Fish Commission Under Superintendence of Deputy Commissioner L. Stone.

[By Herman Dwinelle, late Assistant at the Fishery.]

Part Second.

Work is begun usually about the 15th of July. The first thing done is to erect the large tent for a workshop and hatching cover. This is 100 feet by 30, and is supported by a strong frame and wired to the ground.

It is erected on a gravel plat covered in winter by the river, and everything has to be removed in the fall before the rains begin. As soon as the tent is set up the work of placing cribs in the river, to support the fish harrier, is begun. These are made of logs pinned together, forming a strong, triangular box six or seven feet in hight, two feet of which is to project above the water. A bottom is put to them and they are swung into place, broadside up stream, and held by a rope till filled with stones which keep them firmly in place. These cribs are four in number, and are placed in a rapid just below the tent and have to be renewed every year, as the freshets sweep them away every winter.

After this is done, the old racks of poles that are to stop the fish are overhauled and large timbers being placed from crib to crib, they are placed against them and held in place by stones at the bottom. These reach about a foot above water, and above them are placed frames made of poles with willows woven between, to prevent the fish from leaping over the barrier.

On the tent end of the barrier is an undershot wheel, with buckets for raising water for the hatching troughs. It is twelve feet in diameter and raises 6,000 gallons per hour.

The barrier is usually closed about August 15th, when the great run begins and the fish collect in large numbers in a large pool below, whence they are taken with the seine.

After the barrier is done, the receiving box at the wheel and the flume are put up. The flume is a foot square, about 100 feet long, and carries the water into the filtering tanks. These are two large boxes about four feet by seven by three deep, and have six flannel screens placed obliquely in them to catch the impurities from the water. From them the water passes into the distributing trough, running parallel to them. At right angles to this are placed the rows of hatching troughs, eight in number.

The Hatching Troughs

Are oblong boxes one foot wide, eight inches deep and sixteen feet long, made of sugar pine. These are placed in eight rows, five in a row. They are about five feet above the ground at the upper end and each box has a fall of one and one-half inches, and there is about four inches fall from box to box to aerate the water.

They each contain seven trays made of wire gauze fastened on two wooden frames at top and bottom. Between each tray a dam is put to obtain a circulation of water. These are made of two pieces of one-half inch board about six inches wide and slide in pieces nailed to the sides of the boxes. The first piece is pushed down to the bottom and fastened so that the water is forced to flow over it; the second is placed about one and one-half inches from it about an inch from the bottom, so that the water is forced to flow under it and come up through the eggs placed in the trays to get over the next dam.

All the boxes, troughs and flumes are coated on the inside with asphaltum, which gives them a smooth finish and stops all leaking. It is prepared by putting lumps of crude asphaltum into a kettle, pouring in enough coal tar to fill the interstices and boiling till, when applied with a brush, it will harden quickly.

The Trays

Occupied by the eggs till shipped are two feet long by one wide and seven inches deep, and fit in the troughs as tightly as is consistent with their free working.

The trays for hatching eggs at the fishery were this year made on a new plan by Mr. Woodbury.

The Seining

Ground where the salmon are caught is about 200 yards below the tent. There the river is about fifty yards wide, deep and still, more than is usual; and the fish being stopped by the harrier, collect there and are easily taken from it by the seine.

The seine is about 150 feet long, with four inch mesh, and was made at the fishery this summer. It is drawn by two or three white men, assisted by eight or ten Indians, usually three times a day in the hight of the season, and oftener when the fish become scarce, and at the last five or six times during the night.

As soon as the seine is brought to shore the fish are taken out and each one tried by passing the hand down the belly, and all that are hard or unripe are thrown back into the river, and the ripe ones—those in which the eggs and milt are mature—are put separately into two "corrals" or large boxes (made of pickets) placed in the river, where they are kept till spawned.

It has been till this year the practice to keep all the fish that were nearly ripe in the "corrals" and let them ripen; but it has been found that a large per cent. of the eggs taken from such fish were dead at spawning, and that with the abundance of fish that can be obtained from the river each a course is unwise.

The top of the corral is covered with boards to prevent the fish from leaping out; these boards are fastened with scantling placed across them, whose ends are keyed down. This is necessary, as the salmon in their endeavor to escape, knock off in a night boards that are only spiked down. Their strength in this respect is very great; and were it not for the enfeebled condition in which they are at spawning time, it would be almost impossible to confine them.

The Sacramento Salmon.

After leaving salt water, eat nothing; and although those that pass the fishery in the spring and early summer are in fair condition, by the time of the greatest fall run, beginning about August 15th, the fish are in a most pitiable state, and when the spawning begins about the fishery—they spawn earlier up the river—they are black, thin and covered with a white fungus, and so weak that the mere act of spawning kills them; and not one in one thousand of this ran ever get back to the sea. They die by millions, male and female; and by the time the run is over, October 10th, the clear, cold water of the McCloud river emits an odor that can be smelt for a mile, and the decayed bodies of the salmon are continually floating down it or catching on the rocks. The river does not become drinkable again till the first freshet clears it of this filth. The flesh of the salmon in the fall is white, the fish has no fat and is slimy and coarse. About October 1st a small run comes up from the sea, whose flesh is pink, but these are few in number and soon gone; most of them probably get back to the sea and do not die as the others.

This fact of the destb of the spawners furnishes fish culturists with a problem that has not as yet been solved.

It is said, and has been proved, that salmon always return to their native river to spawn as soon as they are old enough, and consequently as soon as the fish hatched in the McCloud are old enough to spawn, they should return, spawn there and then die; none could reach a very great age, yet a great part of the fish caught are of several years' growth, some being very old, and must have spawned before. They have either spawned in other rivers, or remained several years in the sea.

The Season.

The first ripe salmon are taken about August 26th, and by September 1st the season is fairly begun. The numbers in each haul is small at first and few are ripe, but by September 9th or 10th the season is at its highest, and 500 or 600 are taken at once, of which, often, 200 are ripe. The largest haul this year, made just after dark, was estimated at 1,500, which, allowing 25 pounds as the average, made about 18 tons. From the 10th to the 20th the number of fish taken decreases, though a greater per cent. are ripe; by October 1st the season is over, and by the 10th the river is empty.

The following table shows the result of this year's spawning; only the females spawned are taken account of. Twice as many males were used as females:

Date.	Fem'les.	Eggs.
August 31	14	84,000
September 2	61	221,000
" 3	50	207,500
" 4	101	495 500

The Spawning

Is done on top of the corrals, from which the fish are taken as fast as wanted, in scoop-nets. The work is done by two white men, each assisted by an Indian to hold the tail of the fish; five or six others are employed to catch the fish from the corrals, etc.

In spawning, the females, which average about twenty-five pounds, are held by passing the left hand through the gills. This is necessary on account of the great weight and strength of the California salmon, and is the only way in which they can be held. The eggs are pressed out by holding the fish firmly against the left leg, and passing the hand down the belly till all the eggs are out.

The Eggs

Of this salmon average about five-sixteenths of an inch in diameter and are of a bright salmon color. The average number taken from each fish this year was 4,360. As the fish have to be held by the gills and as any injury to those organs is fatal, and as they would all die any way even if not caught, they are killed and given to the Indians.

The eggs are received in a dry tin pan placed on the floor, the milt is put on them as soon as possible and the two are then carefully stirred with the hand. This dry impregnation—invented by M. Wasski, a Russian, and introduced into this country in 1871—is of the greatest importance, as by the old method of mixing the milt and eggs in water not more than fifty per cent. were usually impregnated, but with the dry method, with sufficient care, all may be.

The manipulation of the males is a working some labor, as they often weigh as high of forty pounds, and have teeth half an inch long and very sharp.

As soon as the eggs have received the milt they are taken by a white man, put in the shade and allowed to stand for about two minutes for the eggs to absorb the spermatozoa. This absorption commences as soon as the eggs are pressed out and continues for ten minutes with diminishing force; after which time they cannot be impregnated.

After standing two minutes the eggs are covered with water and left to stand half an hour for the germ to set. They are then put into large tin pails, about 30,000 in a pail, and washed clean, and then sent up to the tent to be put into the troughs.

At the time of spawning, and probably for an hour or so after, the eggs are tough and not liable to injury and can be handled with great rapidity, but after that they become extremely sensitive and while in the troughs have to be handled with the greatest care, as any sharp jar kills them.

The Tent.

The eggs being taken taken to the tent are there received, measured and put into troughs. They are measured out in a dipper (its contents have been previously counted, a pint holding about 1,600) and poured into the trays in the troughs, 30,000 being put in a tray. There they remain for eighteen days, being every morning stirred up by raising and lowering the tray gently, (all the manipulation has to be done with the greatest care) and all the dead ones (all such are white) are picked out with tin nippers. Seven or eight Indians, mostly females, are employed in picking over the eggs, and do it well.

When the eggs are eighteen days old the eyes of the young fish are plainly visible and then they are tough and can be packed and sent away without danger.

One of the greatest annoyances experienced at this fishery is the impurity of the water. There is in it a fungus that cannot be stopped by the flannel screens or any other means that has as yet been tried. This deposits on the eggs, and unless they are stirred up frequently will in time suffocate them; yet from the constant care that is given them the eggs are kept in better condition than is usual and the mortality is, very small this year about four per cent.

The Packing

Begins when the first eggs are about twenty-one days old. It has to be done with great rapidity, and during the operation the tent presents a scene of great activity—about fourteen persons being then employed.

The work is begun in the afternoon. The eggs are carried in the trays to the upper end of the tent and emptied into a wash tub, where they are thoroughly washed by a stream of water; by which means, also, almost all of those not impregnated are killed.

They are measured out by one man, by dipperfuls, into the spawning pans, and by another handed to four or five Indians (squaws,) who pick out the dead ones. They are then handed to the person engaged in packing them, and by him spread in the boxes.

The Boxes

Are made two feet square by six inches deep, and while being packed are placed in another box filled with water up to the rims on which the eggs are to rest. In the bottom of the box is first a thick layer of moss—the moss used here is all brought forty miles, from Sbasta butte, and is of the finest quality—over this is spread a piece of mosquito netting, to facilitate the unpacking, and on this the eggs are spread from the pans (these are square) by moving them rapidly along over the moss. Here another Indian is employed in picking out *all* dead eggs. Over the eggs on the rims another piece of netting is placed, and then more moss, netting and eggs, and so on till eight layers are in, equal to 40,000. There are three boxes, side by side, packing at once, and the spreader passes from one to the other while the Indians are preparing for a new layer. When each box is full it is left under a stream of water till the time for packing it in the crate.

The Crates

Are two and a half feet by two feet, and are made of half-inch strips, nailed to one and a half-inch corner pieces. In the bottom is put about three inches of straw or fern—the common brake of the hills was used this year—and the box of eggs is placed on it, and then a frame three inches high and open at one side (to form a receptacle between the boxes for ice) is adjusted and the second box placed on top of that, and the whole packed tightly with fern, and the cover nailed on.

The packing is done in an afternoon and morning, and at noon the crates are placed on wagons and hauled to the railroad, at Redding, where they are put on the cars, filled with ice and the whole wet with ice water. The packing is done with great rapidity; as many as eighteen crates, containing 1,410,000 eggs, having been packed at one time this year. All the eggs sent away (6,000,000) were packed and shipped within two weeks. Such is the great superiority of this method of packing over the old method, in glass jars, so tedious and unsatisfactory. The loss by this new method is very small, about four per cent., if they are carefully cared for till they reach their destination, and kept as near freezing as possible.

After the eggs reach the hatching houses, in the East, they are put in troughs and hatched out in about two weeks.

All the carpenter work is done by the employees at the fishery.

The Hatching on the McCloud.

Last year arrangements were made with Commissioner Stone by the State Commissioners, by which 1,000,000 eggs were to be hatched and put into the McCloud, at $1 per thousand, but owing to the largeness of the Eastern shipments, only 850,000 were put in. This year 2,000,000 were ordered, but only 1,850,000 could be furnished, and of these 480,000 were sent to the Truckee and Kern rivers. Those sent to the latter were all killed by the alkali in the water, and it will be impossible to get salmon to grow in it. The lot for the Truckee turned out very well.

The eggs, as stated above, are hatched in trays, from which they pass into the troughs below. Thence they are taken and put into empty troughs, where they are left till they have absorbed the umbilical sac—(when they are about sixty-six days old)—when they are put into the river and left to shift for themselves.

The progress of development of a salmon (*Corogonus Palœa*) egg, translated from the French of Vogt, may be found as an appendix to Commissioner Stone's admirable book on "Domesticated Trout." The time of development of the salmon eggs in the troughs is about as follows: Time till eye spots show, eighteen days; till hatching, thirty-six days; till absorption of sac, sixty-six days. The temperature is 45° to 50° F.

Private Hatching Works.

It often happens that private parties wish to collect eggs in small quantities to replenish a pond or stream, but are deterred from so doing by the expense of building a hatching house, supposing that to be the only method of obtaining them. But it is the opinion of Commissioner Stone and Mr. Woodbury, that all the apparatus used here for salmon can be used with equal success for trout, being a vast improvement on the old systems; and for any one wishing to batch but a few thousand and to expend but little money, a very simple apparatus is available—Mr. Seth Green's shad boxes. These are made by taking a small box, about two feet square by one deep, knocking out the bottom and tacking over it a piece of wire gauze, varying in size according to the size of the eggs—about eight wires to the inch for salmon eggs. This box to be anchored in a stream of clear flowing water, the current is not to be strong enough to disturb the eggs, with the side up stream the lowest. About 50,000 salmon eggs can be put in a box the size of the above. It must have a cover of some black cloth to exclude *all* light.

These boxes have been used to a considerable extent at the fishery, and have been found to work as well, if properly taken care of, to prepare the eggs for shipment, as the troughs, but to require more care.

The eggs could also be hatched in them in small quantities, and as fast as hatched transferred to a "corral" or raceway in the stream in the shade, where they could stay till the sac is gone. Large numbers could not thus be handled, but for collecting eggs in moderate quantities nothing can excel them.

In handling eggs it must be remembered that sunlight is always deadly to them, and any jar, except when they are first taken, and after the eye spots show, is sure to kill numbers.—*Herman Dwinelle in Rural Press.*

Note.—In the table in the first part instead of "eggs hatched," read, "eggs taken."

Influence of Season on the Skin.—Donhoff calls attention to the fact that the obvious difference between the fur of animals in summer and in winter is associated with an equally striking difference in the texture and thickness of their skins. Thus, for example, the average weight of an ox hide in winter is seventy pounds; in summer fifty-five pounds; the hair in winter weighs about two pounds; in summer one pound, leaving about fourteen pounds, to be accounted for by the proper substance of the skin. These differences are quite as decided in foetal animals as in adults. Calves born in winter have a longer and thicker coat than those born in summer; moreover, there is a difference of more than a pound in the average weight of their skins after the hair has been removed. Similar facts may be observed in the case of goats and lambs. That these differences are not to be ascribed to any corresponding change in the diet and regimen of the parent animals is proved by the fact that they are equally manifest in the young of individuals kept under cover and on the same food all the year round.

The Hale & Norcross main shaft is being retimbered and is already finished to a depth of 475 feet.

The Georgetown (Col.) *Miner* calls for a national school of mines.

Scientific Progress

The Production of Phosphorus.

Phosphorus affords a remarkable instance of an article, well known for at least two centuries, but which, until quite recently, possessed but little importance beyond its mere curiosity. The progress of science and mechanical invention, however, during the last thirty years, has given it large commercial importance and made it an almost indispensable requisite in every civilized household. Prof. J. L. Smith remarked in a recent lecture that one of the largest manufacturers of the article, when he was a young man and a student of chemistry, knew it only by a small roll two inches long, which was kept in the laboratory where he studied, more as a curiosity than anything else. This same man now draws it out by machinery, in a rope or cord, many miles in length, and sends it off by tons to all parts of the world.

The improvements made in the manner of its production may be inferred from the fact that in its first use in the manufacture of lucifer matches, it was sold at the rate of $20 per pound; while the price now does not exceed one dollar for the same quantity. This economy in its production has been brought about through the aid of science in the improvement of chemical processes, whereby cheap material can be used in its manufacture.

There are now some fifteen phosphorus factories in the world—one-half of which number is in Germany. The total quantity produced is something over 250 tons annually—about one-half of which is consumed in the manufacture of matches.

One of the most remarkable discoveries in the chemistry of phosphorus was that made about fifteen years ago by Schotter, in producing what is known as amorphous phosphorus. It is only by this wonderful change in its character, by which its inflammability is so reduced as to allow of its being handled with impunity, that its use has become so general and safe in the art of match making.

New Method of Preparing Vermillion.—Recently much attention has been given to the study of this interesting and beautiful compound of sulphur and mercury, the methods of preparing it, and the effects of light and of metals, especially copper and brass, upon the color. Among other interesting results of these studies is the discovery of a new and convenient method for its preparation in the wet way. O. Hansamann has published the following method: A solution of corrosive sublimate is poured into an excess of dilute ammonia, forming a white precipitate of ammonia-mercuric chloride. This precipitate forms flakes which settle to the bottom, and the supernatant liquor contains chloride of ammonium and the excess of ammonia. The precipitate is stirred up with this liquor, and enough of a concentrated solution of hyposulphite of soda is added to dissolve the precipitate, and a little more. On warming the solution in a capsule vermillion at once begins to separate; the heating is continued until a thin pasty mass is obtained. Vermillion produced at a temperature of 120 deg. to 140 deg. Fahr. is of a lighter color than that produced at 200 deg. or 212 deg. The most beautiful pigment was formed at 160 deg. to 175 deg.

Water as a Support of Animal Life.—The first great necessity for the support of animal life is water, for without it the others would be useless. The importance of water will be at once perceived when we remember that seventy-five per cent. of the blood and of the fleshy covering of the body is composed of it, and that from the body in the course of the day about five pounds and a half of water is excreted by the lungs, the skin and the kidneys. It is taken into the body both separately and in combination with other foods, there being, in fact, no food, however solid, which does not contain a certain proportion of it, and of many it forms the largest part. Many succulent vegetables contain eighty to ninety per cent.; potatoes, seventy-five per cent.; new milk, eighty-eight per cent.; and beer, ale, skim milk, etc., ninety per cent. The duties water has to perform in the body are mainly two: it serves to dissolve the food, and enable the nutritive parts of it to be carried into the circulation; and on the other hand, it dissolves out the worn materials and conveys them out of the body. In addition to these functions, by its evaporation from the surface of the body and the air passages it helps to regulate its temperature.—*Cassell's Popular Educator.*

The Transit of Venus.—There is reason to believe that the combined results of the transit of Venus, as observed by all nations, will enable astronomers to determine the distance of the earth from the sun, with no greater probable error than two hundred thousand miles. Before the transit, it was said that at least a year must elapse before any final determination of the sun's distance could be arrived at; it now seems probable that this period of waiting, while the calculations are being made, will extend over many years, and continue, for a verification, until the next transit, seven years hence.

A New Application of the Spectroscope.

There is apparently no limit to the achievements of that marvelous instrument, the spectroscope. It can compel suns and stars to yield up the secrets of their physical and chemical constitution, and can detect a minute adulteration in a phial of medicine. It can analyze rays of light too faint to be discerned except with the aid of the most powerful telescopes, and coming from distances so vast that it has taken years for them to reach our earth; and it can compel a grain of salt dissolved in a hogshead of water to declare its presence by luminous characters that cannot be misinterprated. One of its latest applications has probably been the means of settling a disputed question which it would have been difficult, if not absolutely impossible, to determine conclusively any other way: Do insectivorous plants really digest the insects they entrap?

Darwin has endeavored to prove that they do, but notwithstanding the array of facts he has presented in his recent book on the subject, he has failed to convince certain botanists, who still maintain that the dead insects undergo decomposition, but are not actually assimilated by the leaves. Professor Morren has recently advocated this view with much learning and ability, after a careful investigation of all the phenomena.

It occurred to Mr. J. W. Clark, of England, that the spectroscope might be employed in the examination of this matter. He therefore obtained a number of insectivorous plants, and fed the leaves with the bodies of freshly killed flies soaked in citrate of lithium. He took all necessary precautions to prevent the solution from being carried mechanically to other parts of the plant. After an interval of about forty-eight hours, various portions of the plant were reduced to ashes and tested for lithium with the spectroscope. The colored lines characteristic of that metal at once flashed forth, proving that the products of digestion, after absorption by the leaves, do enter the leaf-stalk, and are thence distributed to other parts of the plant.

If the experiments made by Mr. Clark, and reported by him in full in the London *Journal of Botany* for September, were conducted as carefully as he represents, the results obtained admit of no different interpretation. Other investigators will of course repeat his experiments, and his conclusions will soon be confirmed or contradicted. If the spectroscope has not already put an end to the dispute, we may be sure that it will soon do so.—*Journal of Chemistry.*

Electricity and Life.

Electricity, about which so little is really known, the wonderful possibilities of which have scarcely begun to be developed, has been lifted, by scientific investigation, high above the region of charlatanism, and placed upon the list of positive remedial agents. Why the electrical current, when passed from the nerve-centers along the various branches, is competent to reduce irritation and allay pain, we can only conjecture. The fact exists, however, and the sufferer is more nearly interested in the fact than in the cause. No phenomena are more closely investigated than the electrical, and none are the subjects of wider discussion. The question, "Is Electricity Life?" has been answered affirmatively by many of the leading scientific minds of Europe; and the researches of the most eminent electricians substantiate the fact that a current, precisely akin to that generated by the decomposition of metals, exists in our muscles and nerves; and, further, that in disease this electrical force is essentially diminished.

The unavoidable conclusion from this state of things is, therefore, that electricity is not only life, but life at its best; life, vigorous and unimpaired; and that this energetic, vigorous life, can only be maintained by supplying whatever of electrical force has been displaced or exhausted by incorrect habits of life, by exposure or exhaustion.

The one problem to be solved is this: Shall this subtle fluid, so potent for good if wisely employed, be applied through the poles of the battery, as an electrical "shock," so called, or shall we seek the benefit desired, through the continuous current, by wearing upon the portion to be revitalized such a combination of metals as shall insure a constant though mild electrical action?

The truth is, each method has its specific place—a fact well understood by many medical men. That the simple form—the primary, induced not by the positive decomposition of metals, but rather moist contact—possesses certain advantages, we are convinced; that it is unsafe in unskillful hands is a fact established. The advantages rest in the fact that the current never ceases so long as the appliance is worn; and therefore that the result is cumulative rather than interrupted and spasmodic, and that no unpleasant sensations attend its use. —*Exchange.*

Gas from Cork.—It is said that recent experiments, made in Bordeaux, France, have proved that cork is capable of furnishing illuminating gas of good quality. It is economical and satisfactory. The authorities of Bordeaux have definitely decided to use this material in lighting the city. The fragments of cork, principally waste left after cutting bottle stoppers, are distilled in a close retort. The flame is white and more brilliant than that of coal gas, while the blue zone is much smaller, and the density considerably greater.

Mechanical Progress.

Great Guns—The Old and New.

The contest between great guns and heavy armor plates still continues to excite the liveliest interest among rival nations, and the mechanic and engineer finds ample scope for the exercise of his genius, in keeping up the excitement. Germany and England, in particular, seem to be vieing with each other in this contest.

The English are rejoicing over their new 80-ton gun, while at the same time they are seeking to obtain one of the famous Krupp guns from Germany, with the view of instituting a comparative trial between the two. The steady old German, however, refuses to gratify Johnny Bull's whim; so those two giant powers are going on, each in his own way, and each confident in the superiority of his guns.

Outsiders, however, who are looking out upon this rivalry in an unprejudiced manner, are becoming convinced that whatever may be the power of the English gun, Herr Krupp has fully proven, by actual practice, at his shooting grounds at Visheck, that his 28 and 30 centimeter guns are able to penetrate, readily, 16-inch armor plates. He has, moreover, laid before the German Admiralty plans for constructing guns of 40 and 46 centimeters, before which even the 24-inch plates of the *Inflexible*, probably the heaviest which can be made practicable, would be utterly powerless for protection. Of course, such guns could never be placed on ship-board. Their only use would be for coast defences.

This experiments, thus far, go to show that the limit of resistance in iron-clad is nearly reached, while there appears to be no limit to the use and power of cannon. Forges may be made to glow with mountains of incandescent metal, which nothing but the lack of pecuniary means can hinder from being wrought into guns of larger and still larger calibre.

In this connection it may be interesting to call to mind the fact, that even in these monster undertakings we have only another instance of history repeating itself. Four centuries ago, as is well known, the Turks erected a battery of guns against Scutari, the largest of which was capable of throwing a stone shot thirty-two inches in diameter, and weighing 1,640 pounds, whereas the projectile of the English eighty-ton gun weighs only 1,250 pounds. These enormous guns, moreover, were of practical service, for 2,534 rounds were fired from them in thirty days.

Again, at the castle of Asia, on the Dardenelles, there still exists a battery of bronze cannons, some of which have a bore twenty-eight inches in diameter. When the British admiral, Sir John Duckworth, forced the passage of the Straits, in March, 1807, one of his ships was struck by a huge stone bullet, thrown from one of these guns, and it is said that the missile made so large a hole in the side of the vessel that the captain, when he looked over the side to see the extent of the injury, was surprised to see two of his sailors thrust their heads through the aperture at the same instant.

The great gun of Beejapore, with a calibre of twenty-eight inches, is another instance of what gun founders could accomplish more than three centuries ago. This weapon was last discharged, it is said, during the eighteenth century, on the occasion of a visit from the rajah of Sattara. The shot weighed more than 1,000 pounds. The Tzar Pooshkar, or great gun of Moscow, has a bore thirty-five inches in diameter, but has never been fired with shotted charges.

Immense Wire Ropes.—Commodore Shufelot has ordered the proper authorities of the Boston navy yard to make several five-inch steel wire hawsers. These will probably be the largest wire ropes ever made. The Navy Department has use for immense hawsers to tow monitors and vessels in distress. They are put on board the men-of-war for use when required. The usual appliance is a twelve-inch hemp rope, but it swells when wet and gets very heavy by absorption of water. The steel wire hawsers will be seven inches less in diameter, much lighter, non-absorbent, more pliable and durable, and in every respect better. This is a curious and, in fact, wonderful advance in the application of steel and iron to commercial uses. A hemp hawser twelve inches thick is a wonderful thing in itself, but a steel wire hawser five inches in thickness better answering the same purpose, is something fruitful of thought to the student in shipbuilding and rigging.—*N. Y. Bulletin.*

Reversing the Order. — England is not entirely satisfied with her iron and iron-clad ships. Of the former she has lost several lately, which has induced her, for the passenger and mercantile trade, to try a new style of marine architecture. That is, instead of iron-plating her ships on the outside, she now puts the iron inside. The *Boadicea*, a ship of this kind, has just been launched. Her merits over the old style are yet to be proved, but if she serves the purpose, there will be a complete revolution wrought in English ship-building hereafter.

What May Not the Future Accomplish?

Sir J. Hawkshaw, in a lecture before the British Association, gives the following hint to those seeking new inventions and discoveries.

The marvelous progress of the last two generations should make every one cautious of predicting the future. Of engineering works it may be said that their practicability or impracticability is often determined by other elements than the inherent difficulty in the works themselves. Greater works than any yet achieved remain to be accomplished—not, perhaps, yet awhile. Society may not yet require them; the world could not at present afford to pay for them. The progress of engineering works, if we consider it, and the expenditure upon them, has already in our time been prodigious. One hundred and sixty thousand miles of railway alone, put into figures at £20,000 per mile, amounts to £3,200,000,000 sterling; add 400,000 miles of telegraph at £100 per mile, and £100,000,000 more for sea canals, docks, harbors, water and sanitary works constructed in the same period, and we get the enormous sum of £3,340,000,000 sterling expended in one generation and a half on what may undoubtedly be called useful works. The wealth of nations may be impaired by expenditures on luxuries and war; it cannot be diminished by expenditures on works like these. As to the future, we know we cannot create a force; we can, and no doubt shall, greatly improve the application of those with which we are acquainted. What are called inventions can do no more than this, yet how much every day is being done by new machines and instruments! The telescope extended our vision of distant worlds. The spectroscope has far outstripped that instrument by extending our powers of analysis to regions as remote. Postal deliveries were and are great and able organizations, but what are they to the telegraph? Need we try to extend our vision into futurity further? Our present knowledge, compared to what is unknown even in physics, is infinitessimal. We may never discover a new force—yet who can tell?

Machinery Run Without Lubricant.

Practical mechanics and scientific men have always found a promising field for their inventive genius in devising improved methods of lubricating machinery. We have patent oil cups, patent compounds, patent bearings, and patent anti-friction metals, all warranted to save a large percentage of the cost of lubrication. A few years ago it would have been as feasible for a locomotive to run without steam as to run without oil; now we have the heaviest as well as the lightest machinery running regularly from January to December, without a drop of oil, and without heating or wearing more than it would if lubricants and ordinary bearings were used.

Metaline is the invention of Dr. Stuart Gwynn, a gentleman of wide scientific reputation. The Gwynn centrifugal pump, and the bank note paper used by the United States Government are among his other inventions. The Doctor has labored for a considerable time in supplying "trial bearings" both in this country and Europe.

We shall watch the further progress of this valuable metal with interest. Subjoined are a few references to machinery fitted with metaline in 1870, which is still running, never having been oiled, and showing no signs of wear. Todd & Rafferty Co., Patterson, N. J., a large slotting machine; Isaman Steamship Co., cross-head gibs of 40-horse power engine, run night and day; ferry boat *Newport Belle*, Cincinnati, crank brasses, cross head brasses and gibs; drawbridges on Central railroad of N. J.; Tiffany & Co., N. Y., lathe; John B. Payne, Chard, England, crank pin brasses of 120 horse engine and braces of spindles that make 1,200 revolutions per minute; Adams Express Co., N. Y., crank pin brasses of engine and a Woodward steam pump. A number of the most prominent manufacturers in the United States are now adopting it with complete faith in its efficiency. Some of these we shall refer to in the future.—*American Manufacturer.*

A scientist of Amsterdam reports that he has found in liquid carbonic acid a material that will be of immense service as a substitute for steam in furnishing power for engines; and the idea is considered by some other noted scientists. In this case, as in many others, the practical value of the discovery may not be finally determined till after the lapse of years. The hot air engine and the gas engine were offered to the public as great improvements on the steam engine, and were used in many industrial establishments, but have gone out of favor. Perhaps the carbonic acid engine will not attain even such poor success as they did. The electrical engine has long been promised, but has not yet passed beyond the stage of plaything or curiosity. The introduction of a power superior to steam would make an epoch in history.

Large Sheet of Plate Glass.—The largest polished plate ever exhibited was the work of the Thames plate glass company, measuring nineteen feet five inches long, and ten feet three inches wide. This plate was exhibited at the World's Expositions in London and Paris.

Sales at S. F. Stock Exchange.

MINING SUMMARY.

THE following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

ADVANCE.—Alpine *Chronicle*, Dec. 18: Work on this mine is being pushed vigorously. Since the erection of the building over the shaft, preparatory to placing the steam hoisting works in position, the working force in the shaft has been increased, and the timbering keeps pace with the sinking. The shaft is of three compartments of 4x4½ ft each in the clear, the timbers being 10x10, and partitions 8 inches. They are in ledge matter which bears considerable sulphurets, working easily, and is of a most promising character. The developments made on this property and the elements of which the management of the company are composed, is considered a sufficient assurance of the successful outcome of the enterprise.

AMADOR.

KENNEDY MINE.—Amador *Ledger*, Dec. 18: This mine has been shut down. Both mill and mine are entirely idle, with the exception of the pumping works, which have to be kept going constantly to keep the lower levels free from water. Amid the many rumors afloat concerning the mine, it is difficult to ascertain the real cause of the stoppage of work. There is plenty of low grade ore in sight, which, however, cannot be worked profitably with present milling facilities. The stamps are light, and are not equal to crushing more than twenty-five or thirty tons a day. Heavier stamps will doubtless be put in when the mine is set in motion again, and everything fixed up for putting through a much larger quantity of rock per diem. It is not probable that operations will be resumed before the opening of spring.

HINCKLEY MINE.—The two men engaged on this mine are pushing work as fast as their facilities will allow. We understand that they have been successful in striking a body of rich ore. The ore in this mine has been found in pockets rather than in a definite ledge, and it is thought that one of these detached bodies has now been uncovered. Trouble is being experienced on account of the increased flow of water. A whim will shortly be erected for the purpose of keeping the water within reasonable limits.

BUTTE.

MINING ITEMS.—Oroville *Mercury*, Dec. 17: Every few days some of the honest miners living in the vicinity of Wyandotte, put in an appearance at the bank of Rideout, Smith & Co., to dispose of their enrplus dust. As yet there is a lack of water to carry on the mines with a full head. The water soon runs down and another storm has to be waited for to replenish the small reservoirs. As soon as the Forbestown ditch gets under way this difficulty will be obviated, and mining will go along as in winters past.

FROM Enterprise come good reports. The prospect for a good winter's work was never better. Some new claims have been opened up which look as though they would pay well. At least excellent prospects have been obtained in almost every case. The old claims still show as good results as in previous years. The Electric quartz mine is now all prepared to go to work on very good rock, and much is looked for by those who are best acquainted with the rock.

CALAVERAS.

CLEAN-UP AT THE SAN BRUNO.—Calaveras *Chronicle*, Dec. 18: A crushing of two hundred and fifty tons of quartz, from the San Bruno mine at Mosquito, has recently been made at Garland's mill. The rock yielded an average of $16 per ton, aggregating $4,000. Considering that the quartz was put under the stamps as it came from the shaft, without being assorted, the yield is certainly a good one, fully sustaining the San Bruno's reputation of being among the very best mines in the county.

WEST POINT DISTRICT.—As the shaft of the Cheeno gains in depth the quality of the ore improves. The shaft is evidently about to perforate a heavy ore chute which is dipping towards it from the north. The management of the mine is under the supervision of Mr. Baker, a thorough practical superintendent. The Mina Rica main incline is 280 ft in depth; good ore in bottom. Running levels at 266 ft deep. In the north level the fissure is 5 ft wide, and so easily excavated that one miner makes 4½ ft of headway in 11 hours. The south level is approaching a dike which contaitntes the north boundary for the richest ore chute in the mine. The running of levels accumulates 10 tons of ore per 24 hours on the dump, exclusive of keeping the Enterprise mill steadily crushing. Champion taking out the usual rich ore.

GRAVEL MINING.—Work has now been commenced in nearly all the gravel mines in this vicinity. At Duryea's, in Chile gulch, the "bottoming" operations are still in progress. The gravel in a depression in the bedrock that cannot be got at handily with the hydraulic, is being carried into dump-boxes and washed. The cars, laden with gravel, are drawn by horses. A tunnel is also being run into the bank and preparations made for the resumption of hydraulicing at an early day. Piping goes steadily on in Veith's hydraulic, on Tunnel ridge. Two strings of iron pipe, heading in a "monitor" and leading to different portions of the claim, admit of the continuous use of water. The hand derrick recently put up in the mine works first rate, and is a great help in freeing the "diggings" of boulders. Three hundred inches of water are used and an immense quantity of gravel put through the flume daily. Moser, owner of the Spring Gulch claim, has also resumed washing. His operations are conducted on a large scale, as much as two thousand inches of water being frequently used. Piping is commenced in Cook & Co.'s Sport Hill hydraulic. J. H. Raynor, Esq., a member of the firm, is superintending operations, which are being pushed with unusual vigor. Emerson, proprietor of the Happy Valley hydraulic, has the tunnel nearly finished which will complete the opening of his mine. When ready to commence piping the claim will be one of the best equipped in the county. In Cook & Co.'s Red Hill claim piping was begun some time since. Everything is progressingly favorably.

EL DORADO.

NEW ENTERPRISE IN MINING.—El Dorado *Republican*, Dec. 16: It is a well known fact that there are scores of places in the various branches of the American river where lie untold millions of gold, and it lies there simply because no means could be devised by which the bed of the stream could be worked at these various places. Messrs. Samuel Fleming, of Pleasant Valley, and Captain E. D. Pierce, of Greenwood, have had their heads together on this subject of late, and have hit upon a method that cannot fail to prove successful where the channel is deep. They have located 2,000 feet on the Middle fork, four miles north of Greenwood, part of the location being formerly known as the Old Sardine mine, which so far as it could be prospected proved immensely rich, but as no means could be devised for keeping it free from water, was long since abandoned. The channel here is upwards of forty feet in depth, or rather it is that depth to the bottom of the channel, which is filled with sand and gravel. It is proposed to sink a shaft far enough back from the bank to be secure against overflow or breakage from the channel, to the depth of forty-five feet, and then run a tunnel to and along the bottom of the channel. Messrs. T. K. Young and O. W. Bowles, men of ample means, have taken the contract to open this mine in the manner indicated, and will commence operations without unnecessary delay. All parties interested believe that there are millions in it. The scheme looks decidedly feasible, and we hope the expectations of the projectors may be fully realized.

INYO.

CERRO GORDO.—Inyo *Independent*, Dec. 11: It is reported that Belshaw and Beaudry, (we are not certain that both of these gentlemen are interested) design to put a heavy force to work on the Buena Vista, a large mine but partially developed, and the objective point of the Potosi tunnel, lying to the eastward of the Union. It is also considered settled work generally is soon to start up in the town as in the days of yore, the settlement of the big mining suit removing the only cause that has prevented it before this. No doubt is entertained but the suit is settled, but so far as we know, no positive information has come to hand here yet confirming it, as we learn from Mr. Bennett, one of the counsel and parties in the original suit.

COSO.—Coso *Mining News*, Dec. 11: The Defiance furnace, after running for about three days last week, during which time it produced about eight tons of bullion, was compelled to close down to repair the bottom, which was found to be leaking badly; and also to repair the foundation, which was rendered unsafe by the hot water escaping upon it. During the short preliminary run it made it was satisfactorily demonstrated that the Defiance ores smelted easily, the results showing an average return of $105 in silver and 43 per cent. lead per ton. The fault in the bottom lining seems attributable to the use of an improper kind of clay.

LOOKOUT DISTRICT.—We are informed that parties are now taking ore from the above district to Panamint to have the same worked in the mill there. Since the Surprise Valley company give out their intention to crush custom ores this branch of industry has been stimulated and some of the rich ores from Lookout are to be sent there for reduction. The principal mines are now looking well.

NAPA.

IRON MINE.—St. Helena *Star*, Dec. 17: The San Francisco company, who are prospecting the Iron mountain, at the head of Sulphur Spring creek, have had quite considerable work done, and on Saturday last put in a couple of shots. The ore prospects finely, and should it come up to a certain per cent., on an average, this company propose putting up the requisite works, and will turn out pig iron *ad libitum*. We hope they may have the greatest success in their undertaking, as nothing would help our town more than a well established, properly managed iron mine. That is something to depend on; it is solid.

CALISTOGA MINES.—Work is progressing favorably on the Calistoga silver mine, they having struck a fine vein of ore in the lower tunnel, which looks favorable for striking the main lead. The Calistoga Quicksilver C. M. Co.'s claims, situated near the edge of the valley, about 2½ miles southeast of the town, has the looks of being in a short time one of the leading mines in the State. They have about 360 ft of tunneling on one of the claims and a fine show of metal in each tunnel. Their facilities for working are all that could be desired for a mine; there is no timbering required for the tunnels or shafts, though there is plenty to be had close at hand, the ground being of such a nature that there is no danger of its breaking while tunneling; abundance of water is close at hand. They are now sinking a 100 ft shaft in the center of the lode and are confident of finding the main lead by obtaining that depth.

NEVADA.

RICH AGAIN.—*Foothill Tidings*, Dec. 18: The Carry & Blum claim, over on Rash creek, which turned out several thousand dollars from a pocket nearly a year ago and has not since been much heard from, is again in bonanza. One of the partners, Blum, sold his interest to T. C. Randall, who with Carry has recently opened the portion of the ledge run over before, and they have already taken out from $1,500 to $2,000 in specimens, and we understand the pile of rock now out will give nearly as much more, with pay ore still in sight.

NEW YORK HILL is doing well—keeping the mill running on good rock and sending out gold bricks regularly.

PLACER.

CRATER.—Placer *Herald*, Dec. 18: The new hoisting works of the St. Patrick company, at the Crater mine, are just receiving the finishing touches. The building is completed, and the hoisting engine has been started up. The pumping apparatus is fast being placed in position, when the pumping engine will be put in motion. The rock in the mine continues to look well, and notwithstanding the mill has been kept running day and night since the commencement of the rainy season, the ore dump at the mine is kept piled full. The last clean-up or 16 day's run gave a return of about $14,000, or nearly $1,000 per day.

PLUMAS.

CARRIBOO.—Plumas *National*, Dec. 10: The boys at the old mining camp at Carriboo, on the North fork, are doing finely, and the prospects ahead are first-rate. Hathaway, Drake & Davis recently purchased a claim at that place and are about commencing a tunnel. The indications are that they have one of the best claims in that section.

DUTCH HILL.—The North Fork company's operations are progressing smoothly, and the ground is paying at a rate to satisfy those who have their money invested. The pipe is working nicely this winter, and delivering about 1,000 inches of water at the present time. The tunnel claims are in full blast and paying fully as well as ever. There is no "let up" to Dutch hill, and the old "croakers" and "wise-acres" who predicted a failure are commencing to get over the fence and assert that they "always knew it was a big thing." We wish to see every mining investment in the county pay largely, and are glad to place the North Fork company's success among the certainties.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—Gold Hill *News*, Dec. 16: Both hoisting engines are working to perfection, and the extraction of ore was commenced on Monday last. Upon examination, the shaft was in even better condition than was supposed, and to-day it is the expectation that the extraction of the regular quota of 500 tons of ore per day will be resumed. The works are complete in all their parts, carpenter and blacksmith shops, machine shops and ore dumps; in fact, every department is ready to go into full and complete operation at the same time. In another day the mills will be crushing the rich ore as usual, and the lower levels of the mine will again be yielding up their millions of treasure.

OPHIR.—The new hoisting engine is working splendidly and is kept steadily running, hoisting water from the shaft. The new pumping engine will be ready to start up in a day or two more. The incline hoisting machinery is being repaired, and will be put in good running condition at as early a day as possible. The east ore-house is finished, and the west ore-house for shipping ore by railroad is very nearly complete. In fact, all the buildings and outside works are almost finished. The repairs to the shaft are nearly completed; in fact, everything is approaching a condition that will permit the resumption of ore extraction as before the fire.

LADY WASHINGTON.—About 3 ft per day is the present rate of progress being made in sinking the shaft. Bottom in the same splendid looking ledge matter reported last week, with increase of quartz. No trouble from water, the very efficient pumping arrangements disposing of what comes in without any difficulty. The shaft will be down to the 530-ft level next week, at which point a station is to be opened for a level to explore the mine at that depth.

LEVIATHAN.—Cross-cut No. 4 from the main north drift at the 240-ft level is now being run. It is in good ore, giving excellent assays, and bids fair to show up no extension of the fine ore vein heretofore spoken of at the level. Water does not interfere.

FLORIDA.—The water has subsided considerably, and the machinery being now in good practical trim, nothing interferes with the progress of development. The west drift at the 400-ft level will be pushed forward with the utmost energy and will probably soon cut the main ore vein.

BULLION.—Sinking the main incline is making splendid progress. Driving the main north drift on the 1700-ft level is also making good headway, the face in quartz and ore.

KOSSUTH.—The south drift on the 350-ft level is now in a distance of 240 ft, the face in hard white quartz that assays from $10 to $20 per ton, about one-half silver and the other gold. The winze being sunk below the 200-ft level, 600 ft south of the shaft and 120 ft east of the west wall of the ledge, is down 50 ft, the bottom in quartz that assays this morning $31 per ton. This is a very encouraging prospect and begins to look as if the Kossuth would soon be a paying mine.

CALIFORNIA.—Sinking the C. & C. shaft is making rapid progress. The new battery mill is fast approaching completion. The pan mill is kept steadily running on the Consolidated Virginia tailings. The lower levels of the mine are in fine working condition. The starting up of the Consolidated Virginia hoisting machinery will now soon permit of the resumption of work at all points on the lower levels.

LADY BRYAN.—The main south drift and cross-cut No. 3, on the 380-ft level, are both looking much more favorable for good ore developments soon.

GLOBE CONSOLIDATED.—The ore in the face of the south drift on the east ledge, at the 350-ft level, is showing a decided improvement during the last 3 or 4 days. This drift is advancing further to the southward than any prospecting that has yet been done on that level, and may develop a fine paying body of ore.

BELCHER.—Daily yield, 420 tons of ore. The east ore stopes on the 1500, also those on the 1200-ft level are showing a steady improvement and promise a good yield for many months to come.

LEO.—The cross-cut from the north drift is still in favorable vein material. It is in 34 ft, and now shows signs of approaching the foot wall. The south drift is penetrating ledge matter of a very promising character.

AMAZON & GLASGOW.—The north and south prospecting drifts on the second station level are steadily advancing in the ore vein, the face of both in very favorable quartz and ore.

SIERRA NEVADA.—Sinking the new shaft is making splendid progress, the bottom in good sinking ground.

JULIA.—The shaft is down 1590 ft, the bottom in very favorable ledge matter. The prospects on the 1400 ft level are on the increase, the quartz in the face showing a continued improvement.

CROWN POINT.—Daily yield, 425 tons of ore. No change in any of the ore breasts. The south winze below the 1500-ft level to connect with the main south drift on the 1600 ft level, is making good progress.

SUCCOR.—Sinking the shaft is going steadily forward, although considerable trouble is caused by the strong flow of water at the bottom.

CHOLLAR-POTOSI.—Daily yield, 60 tons of ore. Sinking the combination shaft is making good progress.

SAVAGE.—The pumps are kept steadily running and the water is gradually draining from the lower levels, preparatory to resuming prospecting at all points on the lower levels soon.

MINT.—Sinking the main shaft goes steadily forward. Water does not interfere.

GOULD & CURRY.—The pumps are still doing their utmost to drain the water from the 1700-ft level.

HALE & NORCROSS.—Retimbering the shaft is progressing at the very rapid rate of 20 ft per day, and will be finished in five or six days.

NEW YORK.—Prospecting is going ahead lively at the 400, 600 and 800-ft levels, with very good ore indications at each point. Some little increase of water at the 800-ft level, but the very efficient pumping machinery keeps out the present small flow of water without any effort.

SULLIVAN.—The tunnel has drained the shaft of water completely, and the great width of vein matter developed with good streaks of ore running through it shows very conclusively that rich ore developments will be made at a greater depth. Grading for the new hoisting works progressing finely.

ORIENTAL GOLD HILL.—Ore extraction continues at the rate of 25 tons per day from the south ore body, which amount is being worked at the Hope mill, Silver City. It is excellent looking ore, assays well, and will doubtless make a very satisfactory showing at the clean-up.

IMPERIAL-EMPIRE.—Daily yield, 40 tons of ore. The ore breasts are looking well, and yielding the usual amount of good ore.

JUSTICE.—Nothing new to report of the ore developments at either the 600 or 800-ft levels; work going ahead at both points as usual.

NORTH CARSON.—The fine vein of ore found by the winze from the upper level is showing splendidly, and its full extent is not found as yet. The drift at the lower level is also showing well in its face and giving promise of an ore body soon.

BEST & BELCHER.—Nothing doing on the 1700-ft level, on account of water. The Gould & Curry pumps are steadily draining the water, and it is expected that it will not now be long before everything will be again in running order.

SUTRO TUNNEL.—Two or three streaks of good ore have been passed through during the last few days, and the rock being softer, better progress is made. Total length of tunnel last evening, 11,646 ft.

BUCKEYE.—The bottom of the winze, 100 ft south of the shaft on the 550-ft level, is in very favorable quartz and ore.

In every town and village, persons may be found who have been saved from death from consumption by HALE'S HONEY OF HOREHOUND AND TAR.

Pike's Toothache Drops cure in one minute.

The Sacramento Plow Manufacturing Company.

The cuts on this page illustrate two of the plows made by the Sacramento plow company, an institution now in good order, and kept very busy on its specialty. The company, in addition to the plows, keep on hand cultivators, harrows, etc., and intend building up a larger trade than any other establishment of the kind on the coast. The manufactory is at Sacramento, Nos. 301 and 303 J street. The present establishment, 80 by 160 feet, is found to be inadequate to supply the demand, and another building, 100 by 200 feet, is about to be erected, to be used expressly for the manufacture of this and other agricultural implements. We are told that during the present season orders for the "Iron King" are ahead of the supply. This factory is another of those built up by the progress of California, and we hope it will not be long before the manufacture of other agricultural implements will be carried on on an extensive scale in this State.

Following are some of the points on which the manufacturers rely for the Iron King's becoming popular among the farmers of California: They claim that it runs lighter and works easier for man and beast than any other plow; it turns the furrow better and lifts easier out of the ground. The materials used are all iron and steel except the beam, which is of the best ash. The mold board is of cast steel, and is very thick. The beams are made of wrought iron, and are very strong and high in the throat. The shares are all made from the latest improved patterns, neatly fitted, and are claimed to be stronger than any other in use. They are differently shaped from any other plow, being the result of fifteen years' experience of the inventor. It has Ready's patent center draft, which dispenses entirely with the unnecessary weight of the wheel, thereby lessening the draft, of the plow. The regulating shaft works with ease and precision, and is on the land side of the implement, thus being subject to the control of the right hand of the plowman as he stands on the left side of the plow.

The crook in the forward end of the right hand beam and the manner in which the pole is fastened (not fully shown in our illustration), it will be observed, lessens the draft of the plow. If the beam were straight at the point where the plow goes into the ground a heavy draft is brought upon the wheels, and the harder the plowing the greater the draft. But with this arrangement, which was patented Dec. 3d, 1861, the result is quite the reverse, the draft being up at the point instead of down, and thereby dispensing entirely with the unnecessary weight of the wheels. The saving of power equal to one horse is claimed. The agents in this city are Fleischman, Sichel & Co., 37 Battery street.

Premiums for Skilled Labor.

How often do we see persons enjoying a good degree of success in life who, in all outward exhibitions of natural ability, are rather below mediocrity, while many, to appearance endowed with a far higher order of talent, are not prosperous. Two men equal in native ability are known for exactly opposite conditions of life. Of two laborers, one is always out of employment, the other always in; the whole the result of skill, or want of it, in the pursuit of each. One may, through his own good sense or the advice of friends or wisdom of guardians, have acquired a perfect mastery of his work and he succeeds accordingly, while the other, relying upon his natural tact, is found to fail. Or one may have chosen a pursuit above his ability, and must, therefore, fail, while the other, more modest, seeks a career suited to his powers and succeeds. In every department we find the same contrasts occurring. Those out of employment are the poorest workmen; those who do and have done the least for themselves, are those who have done and are doing the least for their employers. Poor labor is only employed when labor is scarce. The country is overrun with "Jacks"—men of little benefit to themselves or the world, for want, not of talent, but a proper application; a careful patience in an apprenticeship, without which success is hardly possible.

In the great majority of cases the first thirty years of a man's life is of no value beyond the acquisition of a knowledge of himself and the pursuit he is to follow. If he has but one or neither of these at this age, there is still the greater absolute necessity of an immediate application to some pursuit until skill is assured. It is also better to go up than be compelled to come down. It is better to be a successful blacksmith, or carpenter, or bricklayer, than to be an unsuccessful lawyer, doctor, or clergyman. A man below his proper station goes up with grace, while a man above it comes down with a sore head.—*New York Mercantile Journal.*

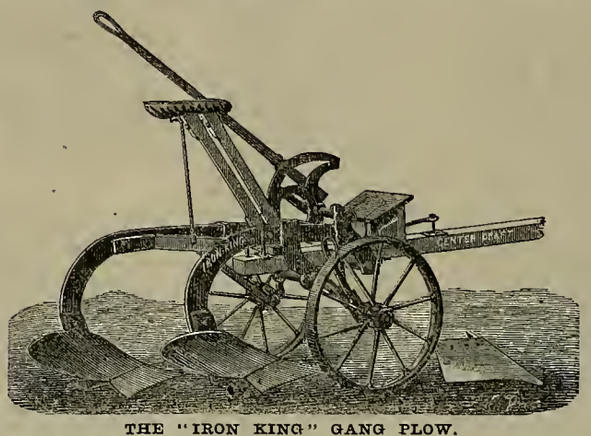
Wild Animals in France.—It is estimated that there are 2,000 wolves in France, which destroy 30,000 sheep a year, beside obliging the farmers to keep 20,000,000 sheep in folds, instead of letting them run in the fields and woods, as in England and America. Wild boars are approaching nearer and nearer to Paris, traces of a herd of about twenty having been observed, a few days back, at Crepy (Oise) a distance of less than forty miles from the capital, a battue was organized, and in two hours fifteen of those animals were killed. The smallest weighed 120 pounds, and the largest 360.

On the Recovery of Silver from Cast Iron Crucibles.

In a recent number of Dingler's *Journal* two Vienna chemists, named Tavorsky and Priwoznik, describe the new methods for obtaining the silver absorbed by cast iron crucibles used in some mints and other establishments for fusing silver and its alloys. A cast iron crucible can be used ten to fifteen times for fusing silver; then the cracks are so considerable that it must be thrown aside. These crucibles were formerly broken up and the bottoms and other portions which contain much silver thrown into the very impure mother liquor from the crystallization of sulphate of copper. This liquor is not easily utilized in any other manner; but on putting in the iron the copper is precipitated, while the iron goes into solution. The cement copper thus prepared, and containing all the silver, along with the graphite silica and other insoluble constituents of the cast iron, is treated in the usual manner for the separation of silver. This process, however, is tedious, and the amount of material to be worked is increased instead of being diminished, for 100 pounds of cast iron yields about 113 pounds of cement copper.

In the Royal-Imperial mint at Vienna, 315 old cast iron crucibles, weighing 115,192 lbs., have been treated in this way, producing 405,574 lbs. of commercial sulphate of iron. The weight of the residue was 23,038 lbs. The poorer portion and the residue from amalgamation, weighing 13,429 lbs., was smelted. Nearly 737 lbs. of silver was obtained, worth 30,143 gulden (about $15,000), from which the percentage of silver in the cast iron is calculated at 0.64 per cent. The amount of silver in a cast iron crucible depends on the richness of the alloy melted in it; those used for rich alloys of course contain more silver than those in which poorer ones are melted. Most of the crucibles worked up so far had been used for the alloy from which the Austrian small change is made, and which contains only 45 to 50 per cent. silver. The results obtained with those in which alloys containing 83.5 per cent. are fused, will, no doubt, be more favorable.

No Time for Long Stories.—Few people nowadays have the leisure or inclination to read long winded editorials, long winded poems, or long winded literary productions of any description. Everybody is exceedingly busy, and if a subject is investigated at all, it must be condensed into the briefest possible limits. The day when histories were written in ten or twenty volumes; when one novel was only a sequel to some other that had preceded it, and so on through an entire catalogue; when editorial paragraphs were elongated to fill one or two columns; and when the ability of ministers or public speakers was measured by the number of hours they could discourse upon any given topic, has happily passed away. The scientific inventions of the present day have quickened life to a wonderful degree. People live longer and accomplish more now in a year than their ancestors did in three or four. Writers of every class, especially writers for the press, should therefore study the art of telegraphic brevity. Make everything as short as possible, consistently with the merits of the subject. Redundancy has gone out of fashion, and "brevity is the soul of wit."



THE "IRON KING" GANG PLOW.

The late director of the mint at Vienna, Von Schrotter, proposed a method for overcoming this difficulty. The crucibles are first broken up and then dissolved in dilute sulphuric acid without heat. To avoid the trouble of evaporating a large quantity of water, in order to crystallize the green vitrol, in the first experiment the sulphuric acid was only moderately diluted, and consequently large quantities of anhydrous protosulphate of iron separated and enveloped the undissolved pieces of iron, protecting them from the action of the acid. As soon, however as the acid was diluted to 20° B., the iron dissolved rapidly. Where chamber acid can be easily obtained it would doubtless be the cheapest. Even with acid of 60° B. it is not expensive, and the latter offers the advantage that the heat generated in diluting it helps the reaction and hastens the solution. The iron is dissolved in wooden vessels lined with lead, 12 to 15 feet long, 6 feet wide and 20 inches deep, with a grating made of lathe, about 8 inches from the bottom, on which the pieces of crucible are placed. As the solution becomes more concentrated, it sinks to the bottom, and the iron is continually brought in contact with fresh acid. If the precaution be taken to cover the vessel tightly the extremely disagreeably smelling gases evolved will not prove a serious disturbance.

SINGLE PLOW MADE BY THE SACRAMENTO PLOW COMPANY.

In from ten to fourteen days the acid becomes saturated and the solution settles and has a concentration of 20° B. By evaporation to 66° B., the green vitriol crystallizes out. The insoluble residue amounts to about 20 per cent. It contains all the silver, silica, graphite, sesquioxide of iron, copper and small quantities of sulphur and phosphorus. The larger pieces of silver are picked out and the smaller are obtained by sifting and amalgamating the residue. Only the old slick and the amalgamation residue, which still contains 1.4 per cent silver, are worked over in the silver works.

This method of recovering silver is much more rapid than that previously in use. It has the advantage that 80 per cent. of iron is removed before proceeding to the recovery of the silver, so that the argentiferous material is reduced to one-fifth its original weight. The experience of those who have employed it in Vienna show that it is thoroughly practicable, and that the green vitriol produced pays for the labor.

A World of Suicides.—Professor Faraday has given it as his opinion that all who die before they are a hundred years old may be justly charged with self-murder; that Providence, having originally intended man to live a century, would allow him to do so if he did not kill himself by eating unwholesome food, allowing himself to be annoyed by trifles, giving license to passion and exposing himself to accident. The French savan, Flourin, advanced the theory that the duration of life is measured by the time of growth. When the bones' epiphysis are united, the body grows no more, and it is at twenty years that this union is effected in man. The natural termination of life is five removes from the several points. Man, being twenty years in growing, lives, or should, five times twenty years; the camel is eight years in growing, and lives five times eight years; the horse is five years in growing, and lives twenty-five years, and so on with other animals.

The Winnemucca foundry, Nevada, has just made a ton and a half of castings for the Humboldt reduction works.

Two of Tulloch's feeders have been put in the mill of the Humboldt mill and mining company.

The Lady Washington shaft will soon reach the 500-ft level.

The Oakville Quicksilver Mine.

Saturday last we paid a visit to this well known mine, and to the courtesy of Superintendent James McQuaid, are indebted for a pleasant call and much interesting information about the mine. The owners are an incorporation known as the "Bella Union quicksilver mining company," a San Francisco company, with 50,000 shares capital stock, par value $100 each; Chas. H. Simpkins, president; A. Halsey, secretary; the Pacific bank, treasurer, and James McQuaid, superintendent. It was formerly the Napa quicksilver mining company, owning the Oakville mine property, but it afterwards bought of Mrs. D. S. Rohlwing the Bella Union mine adjoining, paying her the sum of $15,000, and then incorporated under the new name of Bella Union. The company have 6,000 feet of mining ground, patented, and have plenty of room and rock for years to come. They have two furnaces of the "Luckhardt" pattern, of ten tons capacity each, so that their aggregate capacity is twenty tons per day. Their lode, or vein, is about thirty feet in thickness, and is penetrated by seven different tunnels, some of which enter for a distance of 500 feet. They have a large quantity of ore on hand, and that of a fine appearance. Like other mines, they make "adobes" of the fine ore, but will another season put up a furnace capable of burning this material in the raw, and thus save a cost of manufacture of probably $2,000 to $3,000 a year. The mine, as is well known, was long closed down from litigation with improvident or unfortunate owners, but last July, when everything had been straightened out, recommenced operations under the new owners. It run successfully for about three months, when in October last it was again shut down, and this time from a singular accident. A tunnel run at a long distance from the furnaces, most unexpectedly tapped the water supply of the latter and drew it all off, leaving them like a steamboat high and dry, without anything to run on. Water for a furnace has to be had, for making steam and cooling the condensers, and the result was when this accident happened, all reduction was suspended, and will remain so till the water is pumped back to the furnace, or the furnace removed to the water. This latter would be for a distance of 2,000 feet, and would cost about $10,000. The expense would not, however, be all "dead horse," for it was contemplated at some time or other to remove the furnace anyway, as they are not now in the most advantageous situation with regard to the lode, which further development has shown to lie in a different direction than was at first supposed. It will not, perhaps, be determined to remove the furnaces at once, but rather put in a hydraulic ram to force the water back, which will furnish water enough to supply at least one furnace. The number of men employed now is sixteen, and when engaged in the work of reduction from thirty to forty-five. The men employed now are all Chinamen except three. The mine while in operation was very successful, producing in its 104 days' run 273 flasks of quicksilver, nearly 21,000 pounds. Its product is shipped from Rutherford station to the Pacific bank, treasurer of the company. During the period of this run only one furnace was used; and part of the time inferior ore was run through. The company are getting out a fine stock of ore, and when operations are resumed will doubtless yield a fine return for its labors. The location of the mine is on the mountain side at the west side of Napa valley, about five miles below St. Helena, and at a sufficient elevation to command from its works one of the finest views to be obtained of the beautiful valley it overlooks.—*Register.*

Cleaning Goods By Naphtha.

Naphtha is being used as a cleansing agent for furniture, carpets, clothing, etc., at an establishment recently opened in this city. The process consists simply in placing the article to be cleaned in a bath of hydro-carbon and there leaving it for a couple of hours. Huge vats are used, capable of holding several barrels of naphtha at a time; and in these, sets of furniture or carpet are soaked so as to be entirely submerged in the liquid. No preparation of the goods is necessary, and the naphtha seems to exercise no deleterious effect upon varnish or gilding, upon glued joints, or upon the finest silk or satin fabrics. Dirt and grease are entirely eradicated, the latter sinking to the bottom of the vats, from which it is from time to time removed in the shape of a yellowish mass. Moths are of course totally destroyed.

Several fine sets of furniture were shown us, which had been treated by the naphtha process. They appeared like new so far as the fabrics were concerned, and there was no discernible smell of the fluid. The process is patented. The principal item of expense is the evaporation of the naphtha; but this being allowed for, the cost of cleansing is somewhat less than incurred in the ordinary method followed by clothes-scouring establishments. It may be added that naphtha does not act upon linen or cotton, and it is practically available only upon animal fibers.—*Scientific American.*

On the Glenn farm, in Colusa county, there will be in cultivation this year 37,000 acres, of which Isaac Baylis will have 8,000 acres, Geo. Hoag, 7,000; Pike Gupton, 9,000 and Dr. Glenn, 13,000 acres.

Belcher is expected to pay a $3 dividend in January.

Useful Information.

A New Use for Chicken Feathers.

"According to statistics very carefully compiled," says a writer in *La Nature*, "We throw away yearly a quantity of chicken feathers, the intrinsic value of which is equal to the money which we pay out for cotton." A startling statement, but the author considers it true; and he proceeds to explain how the feathers are prepared to make them valuable. The operation is to cut the plume portions of the feathers from the stem by means of ordinary hand scissors. The former are placed in quantities in a coarse bag, which, when full, is closed and subjected to a thorough kneading with the hands.

At the end of five minutes the feathers, it is stated, become disaggregated and felted together, forming a down perfectly homogeneous and of great lightness. It is even lighter than natural eider down, because the latter contains the ribs of the feathers, which give extra weight. The material thus prepared is worth, and readily sells in Paris, for about $2 a pound. About 1.6 Troy ounces of this down can be obtained from the feathers of an ordinary sized pullet; and this, on the above valuation, is worth about twenty cents.

It is suggested that, through the winter, children might collect all the feathers about a farm, and cut the ribs out, as we have stated. By the spring time a large quantity of down would be prepared, which could be disposed of to upholsterers or employed for domestic uses. Goose feathers may be treated in a similar manner, and thus two-thirds of the product of the bird utilized, instead of only about one-fifth, as is at present the case.

The chicken down is said to form a beautiful cloth when woven. For about a square yard of the material, a pound and a half of down is required. The fabric is said to be almost indestructible, as, in place of fraying out at folds it only seems to felt the tighter. It takes dye readily, and is thoroughly water-proof. There appears to be a good opportunity here for some ingenious person to invent machines to cut and treat the feathers.

Cracking of Paint.

The cracking of either paint or varnish is generally due to the application of a coat of paint or varnish over one not thoroughly hard. It is also caused, in certain cases, by the springing of that portion of the wood or iron, as on the drop-front of a phaeton-body, or on the rims of the wheels, the side-spars, springs, etc., and this cannot be avoided, for the best of painting, as shown on other parts of the job, is no safeguard against it. Another cause of cracking is the swelling of the wood, occasioned by repeated washings, exposure to storms, or by standing in a damp carriage house. This latter cause is entirely obviated by coating the body all over, inside and out, with permanent wood filling, and if the body is to have moldings nailed on, this coating should be done first, in order to have the wood well preserved under the moldings. A firm in New York, who have shipped a great many carriages for long sea voyages, were exceedingly annoyed and put to great expense by the action of sea dampness on their work, but after coating their bodies with this priming, they experienced no further trouble in this respect.

"Fire-checks" are a species of cracks, very small and running in every direction, forming squares, triangles, and circles, which are sometimes to be seen all over a panel, but which are not generally visible until a fine polish is made with the finishing coats. I proved to my satisfaction, not long ago, that these may be caused by a coat put over a surface not hardened; for in this instance, parts of the job which did not receive that "hurried coat" turned out splendidly. "Crawling" of paint, and, to be brief, almost all the "ills that *paint* is heir to," are caused by bad mixing; and as that point has, I think, been sufficiently explained, I will turn now to the devilries of varnish.—*The Hub.*

CHALK.—Most people looking at this substance would take it to be a sort of hardened white mud. Such is not the case, as the microscope shows that it is nothing but the agglomerations of creatures almost invisible. Bearing this in mind, one is astonished at the power of organic life, which can produce masses that form a rampart to the coast of England. Their minuteness is such that a single visiting card covered with a white layer of chalk contains about 100,000 shells. These are formed of carbonate of lime, and are so small that 10,000,000 are required to weigh a pound, and 150,000,000 to make a cubic foot of the same material.

PRESERVATION OF TIMBER.—A German chemist, Sigismund Beer, has found that by using borax as a solvent, the coagulation of sap was prevented, and that it could be effectually removed by boiling, without injury to the tissues. The wood is rendered thereby closer in grain, and is said to become impervious to decay. Wood so prepared is improved both in color and texture, and is free from the danger inherent to impregnation with creosote or other oils. By not washing out the borax the inflammability is said to be much decreased.

A PINT of mustard seed put in a barrel of cider will preserve it sweet for several months.

The Blow Pipe Flame.

The blow pipe flame consists of two distinct cones, the inner and the outer flames. The inner flame is in great need of oxygen, since the air supplied by the blast only affords sufficient to satisfy the demands of the hydrogen in the gas, or hydro carbon vapor; hence, if an oxide of a metal be placed in this cone it becomes heated to a high temperature, and is induced to part with its oxygen to the needy carbon in the flame; thus the metal becomes reduced. This property of the inner flame has procured for it the name of the reducing flame. In the outer flame the complete combustion of the carbon is determined, for much oxygen mingles with it from the surrounding air with which it is in contact. If a piece of metal be submitted to the action of this flame it is heated to a high temperature, and is thus in a condition to be readily oxidized, which is always effected, save in the case, of course, of the noble metals. This flame is therefore called an oxidizing flame. To illustrate the peculiarity of these two flames, place a particle of lead on a piece of well burnt charcoal; direct upon the metal the blow pipe flame, so that the point of the flame may play upon the metal. The lead will melt, then oxidize, and become a transparent liquid bead. Now move the charcoal further into the flame, so that the head may be enclosed in the inner cone. Here it will soon be deprived of its oxygen, and return to the metallic state. This may be perhaps even more strikingly illustrated by submitting a piece of flint glass to the action of the whole flame; that part of the glass which is heated by the outer cone will remain clear, but that in the reducing cone will become opaque, being covered with a dark metallic luster, the fact being that the lead oxide in the gas is reduced.—*Cassel's Popular Educator.*

NEW USE FOR GYPSUM.—It is said that gypsum, mixed with four per cent. of powdered marshmallow root, will harden in about an hour, and can be sawed or turned, and made into dominoes, dice, etc. With eight per cent. marshmallow the hardness is increased, and allows of its being rolled out into thin plates, and painted or polished.

IRON GUNPOWDER.—A composition sometimes called iron gunpowder is made as follows: A mixture of one part sulphur, two parts iron filings, and three parts niter, will ignite by a glowing taper and burn with brilliant light. After it is cold the residue will probably give a red color, due to the ferrate of potash produced by the oxidation of the iron.

Good Health.

A Plea For Late Suppers.

I discussed the question recently with an able physician, who said to me: "There is nothing more absurd than to pretend it is unhealthy to sleep immediately after the day's last meal. Is not man an animal? Do not animals, without exception, sleep immediately after eating? Do we not feel like sleeping after each day's last meal? and is it not by an effort that we shake off sleep? Evidently the body yearns for sleep. Exercise after every meal is pernicious. Rest is healthful. What rest can compare with sleep, which reposes the mind, the lungs, even the heart? See the peasants. No persons enjoy better health than they do. Supper is the best meal of the day. No sooner have they supped than they go to to bed. Look at the actors. There was Ruhini. He dined at three, went to his dressing room in the Italian opera house, and slept till the theater opened its doors. At midnight he supped heartily and straight to bed he went. He died of sheer old age.

You know Monsieur Thiers' habit? The moment dinner ends he stretches himself out to sleep, and sleeps an hour. The truth is, if you look around you, there will be found that this great majority of men go to sleep immediately after making their best meal, and you certainly never saw anywhere in the world healthier, stronger women than those of the great markets. What is the rule of life? Dinner and to bed. Take another, the very opposite class—astronomers. They keep late hours. Their best meal is taken when the stars say "Good-night." Then they go to sleep. Did you ever hear of an astronomer dying under a hundred? The majority of mechanics and servants go to sleep immediately after their best meal. They are right. They obey nature's voice, which always gives judicious advice.

CARE OF THE EAR.—In his treatise on Physiology, Hinton gives us to understand that the passage of the ear does not require cleaning by us; nature undertakes that task, and in the healthy state fulfils it perfectly. Her means for cleansing the ear is the wax, which dries up into thin scales and peels off and falls away imperceptibly. In health the passage of the ear is never dirty, but an attempt to clean it will infallibly make it so. Washing the ear out with soap and water is bad; it keeps the wax moist when it ought to become dry and scaly, and makes it absorb dust. But the most hurtful thing is the introduction of the corner of a towel screwed up and twisted around. This proceeding irritates the passage and presses down the wax and flakes of skin upon the membrane of the tympanum, producing pain, inflammation, and deafness. The washing should only extend to the outer surface, as far as the fingers can reach.

Treatment of Erysipelas.

A Berlin medical journal reports a new mode of treating erysipelas, since the introduction of which into several of the hospitals at Posen no fatal case has occurred. The affected parts of the skin are gently painted over every three hours with a mixture of one part of carbolic acid and three parts of oil of turpentine; and the same is rubbed somewhat more energetically into the adjacent parts. Compresses dipped in lead ointment are then applied, and lastly, according to the extent of the disease, either an ice-bag is laid upon the part, or the whole limb is wrapped around with cloths dipped in ice cold water, and these must be promptly changed for fresh ones as soon as they become all warm. When adynamic symptoms are present, Hungarian wine is given, and camphor mixture. The bowels should be kept open. The parts rubbed with the mixture become very red and even blistered; but the epidermis soon dries and the skin appears as if tanned. The progress of the disease is arrested in from twenty-four to thirty-six hours, and no relapse occurs.

The Cranberry Cure.

From time to time articles have gone the rounds of the press stating the value of the cranberry cure as applied in erysipelas, and so wonderful have the cures effected seemed, that many are disposed to take the stories with a grain of allowance. But now, says the Sacramento *Herald* of a late date, we have a case in this city, where a remarkable cure has been effected, and the patient is around and able to testify to the wonder of this simple remedy. Judge Cantwell, of the police court, about two weeks ago, was taken with an attack of erysipelas in the left leg and in a short time the disease increased to an alarming extent, running well up into the thigh. The usual poulticing with flax seed, etc., was resorted to, but no relief was had, and the sufferings of the patient increased. Last Thursday, however, a friend suggested to him that he try the cranberry cure, whereupon the Judge got the berries, had them well bruised and applied to the injured limb, and after the poultices had been on but a few hours he expressed himself as experiencing greater relief than at any previous time during his illness. The remedy was continued, and this afternoon the Judge had so far recovered as to be able to leave his room and take a carriage ride, and in a day or two he will be able to resume his official duties. Naturally he has now a strong faith in the curative properties of the cranberry and is loud in the praises thereof.

Blood Cure — Digestible Blood Powder.

The powder obtained by the evaporation of blood is nearly as insoluble in water as sand, and is quite indigestible. The preparations met with in commerce under the name of *extract of blood* are not quite so insoluble, but the absence of hæmoglobin in them (which forms 86 per cent. of the corpuscles) can be easily shown by the spectroscope. Having lately required a large quantity of blood for researches on this liquid, M. Le Bon sought to reduce it to powder without altering its composition and properties, and he believes he has succeeded in doing so by operating (with special apparatus) at low pressure and a temperature not above that of the body. He showed the French Academy a specimen kept eighteen months. You shake the powder in water a few minutes, then filter the solution, and thus obtain a beautiful red liquid having all the properties of defibrinated blood. In pepsine the powder is shown to be perfectly digestible. M. Le Bon points out that this soluble blood, which has parted with four-fifths of the water it contained, is a most nutritious aliment with small volume. It might be associated with farinaceous food, and thus a diet would be provided physiologically complete. Its richness in iron and its tonic properties render it also a valuable therapeutical agent.

HOW TO HAVE SOUND TEETH.—The *Science of Health* says: Mushes, gruels, puddings and soups may be made hygienically. But they should also be eaten hygienically. They must be chewed, not bolted. The nursing infant masticates its mother's milk, for which purpose it takes it slowly, drop by drop. Mastication is for the purpose of insalivation. Unless food is properly insalivated, it cannot be well digested. The teeth are the finest, densest structure of the body, and this means that they are intended for hard work. Eat solid food at every meal; and when you take semi-liquid, or very soft food of any kind, eat very slowly and take a bit of hard bread, crackers, a green apple, or something similar, with it. Then will your stomach please and be pleased, and your teeth, like your eyes and nose, and fingers and toes, will remain to bless and comfort you to the last. If all persons after being weaned, would only chew their food enough, we would hear very little of aching and rotting teeth, and dentists would be nowhere.

A CHOKING SENSATION.—A beggar entered Britton's saloon, No. 12 Greenwich street, New York, and asked for something to eat. A man named McCutcheon offered him a piece of meat, and as he was about to take it, withdrew it and put it in his own mouth, at the same time uttering an anathema against beggars. He had no sooner made the remark than he commenced to choke, and before assistance could be offered he died, having been choked to death by the piece of meat.

Domestic Economy.

Cooking.

There is no more important branch of "preventive medicine" than cooking. Bad cooking may cause a dwindling of the race, ruination of the temper, and deterioration of the morals. Good cooking, on the other hand, is accompanied by national prosperity and domestic bliss. So say the promoters of the national training school of cookery, who are undoubtedly right in the main, and are deserving of all imaginable success. Now, cooking is both an art and a science. For its progress as an art we are not greatly concerned, although our profession would undoubted suffer in pocket should fine art cookery go out of fashion. "Elegant" dishes are generally whited sepulchers, and the fore-runners of blue pills and other disagreeable correctives. The bulk of people live in big cities, and if we were asked to name the most predominating characteristic of our urban population, we should say "dyspepsia." Those who spend their days in dark offices, chambers, or consulting rooms, and keeping their noses everlastingly upon their respective grindstones, seldom know that digestion which should wait on appetite. Hitherto their dinners have not been so skillfully prepared as to demand the least possible effort from a jaded stomach; but let us hope that the national disgrace of indigestibility will no longer dim the brightness of our hospitality, and the number of patent medicines which are sold so largely in this country as aids to digestion will undergo a rapid diminution.—*Ex.*

RIGHT WAY TO BOIL EGGS.—There is an objection to the common way of boiling eggs which people do not understand. It is this: The white, under three minutes' rapid cooking, becomes tough and indigestible, while the yolk is left soft. When properly cooked eggs are done evenly through, like any other food. This result may be attained by putting the eggs into a dish with a cover, as a tin pail, and then pouring upon them boiling water, two quarts or more to a dozen eggs, and cover and set them away from the stove for fifteen minutes. The heat of the water cooks the eggs slowly and evenly and sufficiently, and to a jelly-like consistency, leaving the outer or yolk harder than the white, and the egg tastes as much richer and nicer as a fresh egg, and no person will want to eat them boiled after having tried this method once.

TO WASH SILK.—Among the many ways of washing silk the following will be found equal, perhaps, to the best: Half a pint of gin, four ounces of soft soap, and two ounces of honey, well shaken. Wet a sponge with this mixture, and rub the silk, which should be spread upon a table. Then wash it through two waters, in which put two or three spoonfuls of ox gall, which will brighten the colors and prevent them running. Do not wring the silk, but hang it up to dry, and while damp iron it. The lady who furnishes this recipe says she has washed a green silk dress by it, and it looks as good as new.

AN IMPROVED DUMPLING FOR CHICKEN, STEWS, ETC.—With one quart of sifted flour mix one teaspoonful of salt, two of cream of tartar and one of soda. Pour in sweet milk and stir until the mixture is just thick enough to form into biscuit. Place them upon the largest sized, round baking tin, and set the tin in a steamer over the kettle where the chicken is boiling. Steam about forty minutes. Thicken and season the broth, break the biscuit apart and drop them into the gravy, boil ten minutes and serve. These are said to retain their lightness, not falling as they become cool.

CRANBERRY MARMALADE.—Sweet and sipid apples, and those which are past their prime and need to be cut up on account of decay, made be very acceptable by stewing and mixing with stewed cranberries in the proportions say of one part cranberries to two parts apple. Not quite so much sugar will be required as for the cranberries alone, unless the apples are sour. Strain through a colander, mix evenly, and serve at any meal.

NEWFOAT FISH PUDDING.—Pick cold fish into small bits, removing all the bones. Thicken some boiling milk with flour, and stir the fish into it, season with butter, pepper, and salt. Put into a pudding dish, and spread cracker or bread crumbs thickly over the top, to prevent the milk from scorching. Bake only long enough to brown it nicely. A good breakfast dish, or a side dish for dinner.

STEAMED OYSTERS.—Wash the oysters thoroughly, and place them in a colander, covering with a lid; put enough water into the kettle to get up a good steam. The oysters will soon open, when they are done. I suppose any perforated pan fitting snugly on the kettle would answer in place of a colander. This is the best way to cook oysters.

TO KEEP LEMONS.—Housekeepers know how quickly lemons lose their freshness, and rot. A simple and inexpensive remedy is to place them in a jar filled with water, to be renewed every day or two. By this means the fruit can be kept fresh and sound for several weeks.

MINING AND SCIENTIFIC PRESS.

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, W. B. EWER, GEO. H. STRONG JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week.	1 month.	3 months.	1 year.
Per line..... .25	.80	$2.00	$5.00
One-half inch.....$1.00	3.00	7.50	24.00
One inch..... 1.60	4.00	12.00	40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, $4; six months, $2.26; three months, $1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary loaded matter.

San Francisco:
Saturday Morning, Dec. 25, 1875.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Device for Producing Blast or Vacuum in Laboratories, 401. "Iron King" Gang Plow and Single Plow Made by the Sacramento Plow Company, 406. Harrison's Grinding Mills, 408.

GENERAL EDITORIALS.—Apparatus for Producing a Blast or Vacuum in Laboratories; Academy of Sciences, 401. MINING AND SCIENTIFIC PRESS for 1876; Our Merry Christmas; Mechanics' Institute Fair, 408. The State Geological Survey; That Quicksilver Contract; Improved Grinding Mills; The Fryer Process; General News Items, 409.

SCIENTIFIC PROGRESS.—The Production of Phosphorus; New Method of Preparing Vermillion; Water as a Support of Animal Life; The Transit of Venus; A New Application of the Spectroscope; Electricity and Life; Gas from Cork, 403.

MECHANICAL PROGRESS.—Great Guns—The Old and New; Immense Wire Ropes; Reversing the Order; What May Not the Future Accomplish? Machinery Run Without Lubricant; Large Sheet of Plate Glass, 403.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 404.

MINING SUMMARY from various counties in California and Nevada, 405.

USEFUL INFORMATION.—A New Use for Chicken Feathers; Cracking of Paint; Chalk; Preservation of Timber; The Blow Pipe Flame; New Use for Gypsum; Iron Gunpowder, 407.

GOOD HEALTH.—A Plea for Late Suppers; Care of the Ear; Treatment of Erysipelas; Blood Cure—Digestible Blood Powder; How to Have Sound Teeth; A Choking Sensation, 407.

DOMESTIC ECONOMY.—Cooking; Right Way to Boil Eggs; To Wash Silk; An Improved Dumpling for Chicken, Stews, Etc.; Cranberry Marmalade; Newport Fish Pudding; Steamed Oysters; To Keep Lemons, 407.

MISCELLANEOUS.—McCloud River Salmon Fishery; Influence of Season on the Skin, 402. The Sacramento Plow Manufacturing Company; Premiums for Skilled Labor; Wild Animals in France; On the Recovery of Silver from Cast Iron Crucibles; No Time for Long Stories; A World of Suicides; The Oakville Quicksilver Mine; Cleaning Goods by Naphtha, 406.

Mechanics' Institute Fair.

A meeting of the managers of the Mechanics' Institute fair was held Saturday evening, as announced in our last issue, for the purpose of distributing the prizes awarded at the late fair. Those who were not present to obtain their certificates may obtain them from Mr. J. H. Culver, at the Institute. President Hallidie read a report of the receipts and disbursements as follows: Sale of tickets for the Tenth Industrial Exhibition, $84,515.75; sale of privileges, $5,254; sale of catalogues, $288.50. Total, $90,058.25.

Expenditures—Fitting and decorating, $10,241.38; running expenses, $28.702.13; horticultural garden, $6,706.31; contingent expenses, $10,578.14. Total, $56,227.96. Profit, $33,830.29.

From the report read by the President it appeared that the buildings and fixtures cost $106,330.60; running expenses of the Ninth Industrial Exhibition, $5,464; contingent expenses do, $2,193.46; receipts from Ninth Industrial Exhibition, $84,684.26, leaving a deficiency of $49,303.90. The ball given last year netted $2,797.47. In about thirty days a full report on the late exhibition, compiled by Mr. Culver, will be published.

ALEXANDER DEERING, judge for the Thirteenth judicial district of the State of California, died at Merced on the 18th inst.

MR. O. SEAWELL will please send his P. O. address to this office.

[PUBLISHERS' ANNOUNCEMENT.]

MINING AND SCIENTIFIC PRESS For 1876.

THIS PUBLICATION, SO VALUABLE FOR MINERS, MECHANICS AND MANUFACTURERS,

Will enter upon its THIRTY SECOND Semi-Annual Volume on Saturday, January 1st, 1876. It has ever been and will still continue to be the aim and object of the publishers to make the PRESS

A Practical and Interesting Journal.

To this end, we aim, through the constant watchfulness of our editors and correspondents, to seize upon everything new in the way of mining and the various processes connected with the saving and separating of the precious metals, and place the same before our readers at the earliest day. It has been well said that

A Newspaper is a Window

Through which men look out upon all that is going on in the world. Our window is a special one, so placed and arranged as to bring within the scope of its vision all that is going on

In the World of Mining, Mechanics and Science.

Without a paper of this kind, the miner or mechanic is shut up in a small room or shop and can know but little of what is going on in the world around him in relation to his particular calling. In this age of rapid progress books are necessarily slow and behind the times. It is only through papers devoted to the specialty which he has chosen that one can be easily apprised of the discoveries and improvements which are constantly being made by his fellow workers, and without a knowledge of which he soon becomes a laggard in the race.

The Value to the Community

Of such publications in disseminating important information, in checking useless and exploded experiments and in instigating important enterprises, can scarcely be overrated. Through them the readings and observations of thousands are collected and collated, and brought directly to the shop or table of the reader, without any effort of his own. For a mere trifle of cost he is regularly furnished with an encyclopedia of just the information he needs—an unbound book forever issuing but never finished.

Nowhere in the Wide World

Is such an aid more needed than by the miner of California. It is needed alike in the mill, in the mine and in the placer. We have here

The Largest Mining Field on the Globe,

Embracing a variety of minerals nowhere else found within the boundaries of a single field. We have here, also, men gathered from every quarter of the globe bringing with them the collective wisdom of the world,

Useful, Practical and Directly from the Field

Of labor. The mustiness of books has been brushed away, and their minds are stored not only with the experience of the past, but also with the practice of the present. It is to this fact that we are indebted for our present

Able List of Correspondents,

Through whom we are able to promise to our readers so much that cannot be collected in the mere routine of office work. By the aid of such help our editors will be able, during the coming year, to do more than ever in furnishing information which shall be

Fresh, Novel and Interesting,

And which shall comprise all that is known of the latest and best means for saving gold and silver, and for economizing labor and cost in that direction.

Our Illustration Department

Will still continue to form an important feature, and no effort will be spared to make it of the greatest possible local and general interest to our readers. The important matter of

Home Manufactures and Inventions

Will also largely occupy the attention of the publishers and editors, and will be constantly encouraged, as an important means of furnishing employment to those who are seeking our shores, and adding to the wealth of the Pacific coast.

The Large and Increasing Circulation

Of a journal thus devoted exclusively to useful and practical information, speaks more in our behalf than anything we could say of ourselves, and is an encouragement to its further increase, especially in these times of trifling and trashy journalism.

A Handy Map

Of California and the principal portion of Nevada will be furnished free to all subscribers who pay one year in advance, during the year 1876. The map is plain, printed on tinted paper, about 16x20 inches, showing townships in California, and the counties, railroads and principal towns in California and Nevada.

We Prepay the Postage

On all papers sent to subscribers in the United States.

The class of readers who are interested in such a publication as this, have no need to be anything more than merely reminded that such journals are necessarily more costly than those of a lighter class, such as are read by the "million" and thrown aside as soon as read. Considering the character and location of the MINING AND SCIENTIFIC PRESS, our rates are as favorable as can possibly be afforded and do justice to the great industries in aid of which we are laboring.

SUBSCRIPTION RATES, payable in advance: One year, $4. Sample copies free to those who will assist in obtaining subscribers.

DEWEY & CO., Publishers,
No. 224 Sansome street, S. F.

Our Merry Christmas.

When people go about proclaiming that "Christmas comes but once a year," it is not presumed that they suppose the rest of the world to be ignorant of the fact, but when their neighbors fully realize the fact that this,

The Greatest of all Holidays,

Occurs but once in the course of twelve months, it is expected that they will considerately make some allowances for the ebullitions of joyous feeling exhibited on this occasion.

Preparations are making for keeping this glorious holiday in a becoming manner. The growth of Christmas trees in the streets of San Francisco within the past week has been extremely rapid, and this novel feature of vegetation has undoubtedly exhibited the same marvelous growth in other cities and villages of California. We have much to thank our recent rains for, but they did not produce these green, fragrant Christmas trees. They had their growth in the hearts of the people. Sidewalks are obstructed with them in a way that would not be tolerated on any other occasion; but the policemen recognize a power behind the municipal throne, in the holiday feeling that produced these trees, and they only see them to admire and to be reminded that they were boys themselves a great many years ago.

These trees are of all dimensions and shapes, but are all the greenest of the green, and may all be known even without their fruits; but when on Christmas morning their generous harvests are offered to the grateful hearts of the rising generation, who can compute the value thereof! The variety of this fruit is as marvelous as its abundance. And then how unostentatious are all these Christmas offerings! The poor laboring man who makes a present of a cheap doll, a miniature wagon or some other substantial toy, would have the world remain forever as oblivious of the cost, as the favorite of fortune who hangs his rich gifts upon a tree that perhaps grew by the side of that to which his poorer neighbor fastens his cheap toys—which offerings were prompted by impulses having their growth in the same trait of human nature.

And another thing; we do not believe that the festivities of the season are any way dependent upon the magnitude of the snowbanks, upon the jingling of sleigh bells, or upon the freezing of fingers and toes, and, for our part, the supply of fresh strawberries and grapes which we have seen this week along Sansome street, shaded by the Christmas trees described above, did not lessen our anticipations of Christmas joys. And while we shall say nothing disparagingly of the pleasures which our friends at the East enjoy over their red hot stoves, still we cannot dispel the delusion that Christmas is just as merry where no fire is needed.

But this particular Christmas brings with it one coincidence over which we are especially merry. It is the fact that our paper bears the date of December twenty-fifth. There are, therefore, no anticipations, or no make believes of any kind, involved, when we wish our many friends

A Merry Christmas,

And that our intercourse may continue mutually pleasant and profitable. And though we have no right to expect that the Christmas trees of our readers will bear any fruit for our picking, we shall take the liberty on this occasion to assure our friends that for our part we shall continue to harbor the belief that we are bound by a closer tie than those that are created and maintained by mere selfishness.

THE North Pacific Coast railroad company are to construct a bridge for the new side track which is building on Paper Mill creek, tapping the Lagunitas canon. The bridge is to cost $5,000.

Legislative.

Our legislators seem to be pretty hard at work at Sacramento, judging from the number of bills introduced. Our space forbids our publishing many of the bills in full, although we shall keep our readers posted on such measures as effect general industrial interests. We note the following matters of general interest: A bill providing for a system of irrigation has been introduced, which is substantially the same as that brought up last year. Raymond, of the Senate, offered the following resolution:

WHEREAS, The policy of permitting the lands in this State to be monopolized in the hands of the few at the expense of the many, is subversive of the rights of the people and ruinous to the best interests of the State, therefore be it

Resolved, That the Judiciary Committee of the Senate be instructed to prepare and report to the Senate at an early day a bill to prevent the evils arising from land monopoly. Carried.

A bill has been introduced to regulate fare on street railroads in San Francisco.

Senator Tuttle's bill (63) to estsblish a State reformatory provides for a reformatory department at the State prison at Point San Quentin. Sec. 2 reads: "The Board of State Prison Directors shall proceed as soon as funds shall be appropriated by the Legislature for that purpose, to erect suitable buildings for the said State reformatory, having a capacity for not less than 400 inmates, and constructed if practicable with a view to the classification of prisoners; said building shall be erected outside of the present wall, and shall be enclosed by a suitable wall." On the completion of the buildings the Governor is to give notice thereof by proclamation, to be published once a week for six weeks in a newspaper in each judicial district. After said proclamation any person under twenty-five years of age convicted of felony, who has not been previously convicted of such a crime, shall be sent to the reformatory instead of the State prison for the same number of years for which the person so convicted would have been sentenced to the State prison. The amount appropriated under the bill is $75,000 for the erection of additional cells, and a similar amount for additional shop room, to be expended during the years 1876-77.

Senator Piersons has a bill to increase the State University library. The proposal is that on the institution of a civil suit, the plaintiff shall pay to the clerk of the court in which it is brought one dollar, to be applied to a fund to be known as the "University of California library fund."

The State Marine Board has been abolished.

The following resolution was passed:

WHEREAS, The candidates of the different political parties, at the last election held in San Francisco, pledged themselves, if elected, to use their best endeavors to reduce and make equitable the present exorbitant water rates in the city and county of San Francisco; therefore be it

Resolved, That a special committee of five be appointed by the House to act in conjunction with a similar committee of the Senate, for the purpose of collecting data as to the cost of getting water in San Francisco as compared with the cost of getting the same in other large cities, and that said committee be instructed to report on or before January 18th, 1876.

The following were appointed as the committee when the resolution passed, Donovan, Roach, McCoppin, Bartlett and Howe.

Mr. Ferral has introduced a resolution to discourage Chinese immigration.

Archer moved the adoption of the following:

Resolved, That the charges for fares and freights on railroads in California are subject to the control and should be regulated by an act of the Legislature, with a view to the protection of the people from injurious discriminations and unjust charges by railroad companies, but in a spirit of fairness to the owners thereof; that the said subject of fares and freights be referred to the Committee on Incorporations, with instructions to report a bill in relation thereto.

The resolution was adopted.

The following resolution has been referred to the Committee on Commerce and Navigation:

WHEREAS, Representations have been made to members of this House and the people of this State, through the public press, that there are a number of steamships sailing to and from the port of San Francisco, carrying passengers, that are rotten and unseaworthy; and

WHEREAS, A number of steamships sailing to and from San Francisco have been lost, together with a large number of lives, within the last few years, through unseaworthiness and without other cause; therefore

Resolved, That a committee of five be appointed by the Speaker, whose duty it shall be to proceed to the city of San Francisco with authority to examine into the facts and procure such evidence as is necessary in the case, and report the same back to this House for further action.

Lindsay has proposed a joint resolution asking Congress to restore to the public domain the Atlantic and Pacific railroad reserve lands.

Both Houses will adjourn over the holidays and meet again January 4th.

END OF VOLUME.—This issue of the MINING AND SCIENTIFIC PRESS concludes Volume XXXI, and we write the last lines in this only to begin with renewed efforts and encouraging prospects on the next. The copious index on the last page of this issue will give an account of our work, and we commend its perusal to those interested in industrial pursuits, so that they may see whether they can afford to be without a paper which has given such a variety of valuable reading matter in the last six months. The index itself is a matter of no little labor, but to those having bound volumes of the PRESS it is of course invaluable. We wish our readers all a "Merry Christmas," and trust that most of them will still be "our readers" at the end of the next volume as they are at the end of this.

The State Geological Survey.

The following memorial to the Legislature has been prepared by the California Academy of Sciences in relation to the resumption of the State Geological Survey:

To the Honorable the Senate and Assembly of the State of California:

The California Academy of Sciences would respectfully represent that the Geological Survey is a work of great practical importance, as well as scientific and educational value to the people of this State.

That by the action of the Legislature of 1873 and 1874, the accumulated and unpublished material of several years' work was placed for safe keeping in the custody of the Regents of the University, where for want of further provision the greater portion still lies unimproved.

That there has been already published four volumes of the Geological reports, viz: One of Geology, two of Paleontology and one of Ornithology, besides smaller pamphlets and several topographical maps, the beauty, accuracy and value of which are appreciated and acknowledged by all who have carefully examined them.

That of the unpublished matter already accumulated, there is the material for a second volume of Geology, for a volume of Botany nearly ready to be issued, and the greater portion of the material for a second volume of Ornithology, devoted to the aquatic birds.

That the map of Central California is so nearly finished that the active field work of one more season would complete it. This map embraces nearly one-half the area of the State, and extending from Lassen's peak on the north to Visalia on the south, includes all the more important mining districts within the limits of California. The work so far done upon it is unexceptionable, and when completed it will possess the highest practical value, will meet with a ready sale, and be the most important contribution to the geography of this coast that has ever been made.

That a general geological map of the whole State has been partially drawn and colored, and could be finished and published in such a way as to show the extent of present knowledge of the geology of the State (subject of course to such improvements in detail as may hereafter be developed by future work) at no great expense.

That the United States Coast Survey map of the peninsula of San Francisco has been geologically colored, in great detail, and only waits the means for its publication.

Finally, that these unpublished works are all greatly needed for the benefit of our public schools, as well as for all the higher educational interests of the State, and that when completed they would convey the most accurate information with regard to our coal fields, quicksilver mines, quartz veins and hydraulic washings, which cannot fail to exercise a most beneficial influence in aiding the further development of these important industries.

In view of the foregoing facts, the California Academy of Sciences would respectfully pray that your honorable bodies revive the State Geological Survey, and make a liberal appropriation for its continuance and completion.

HENRY EDWARDS, Vice-President. CHAS. G. YALE, Secretary.

That Quicksilver Contract.

An item has been going the rounds of the press to the effect that the Redington quicksilver company had a contract to supply Flood & O'Brien with 400 flasks of quicksilver per month at $1.50 per pound, the contract having a year and a half longer to run. If this were so the Redington company would have a pretty good thing supplying that quantity of quicksilver at double the market price. It happens, however, that the item is n't correct. The contract between these parties was that 400 flasks per month should be furnished at a price not over $1.50 per pound, no matter how high it went; but, of course, the market price only was to be charged.

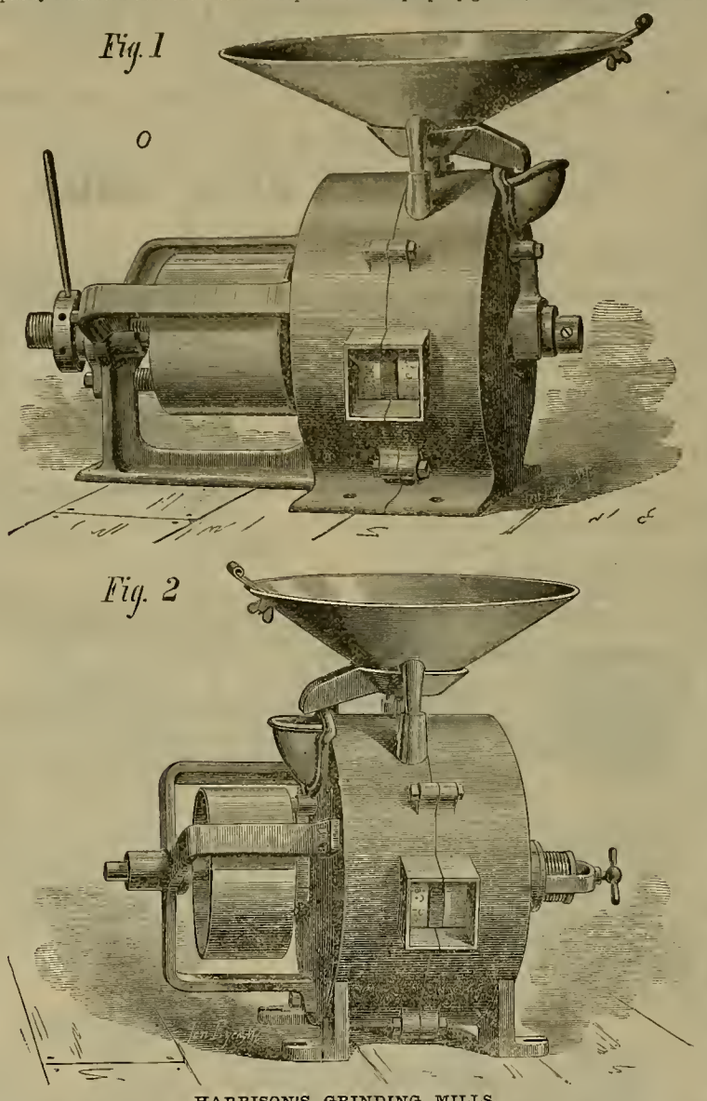
When the Redington company saw that quicksilver was going down they naturally desired to make a contract, so they made a contract for a large quantity at a low price. When it was really selling at $1, they agreed last March to sell it for seventy cents per pound, and furnish 400 flasks per month at that price, which is the market price now. Since then it has been lower and higher, so the contract was good enough for both parties. This contract expires in March. Flood & O'Brien had the quicksilver at the market price, and the Redington company could afford to hold the remainder of the product for a better price. Accordingly when it was selling at seventy cents they kept back the remainder of the product until the price came up again. So they made the most of the market.

The Redington is now turning out about 1,000 flasks of quicksilver per month and paying $50 dividends right along. There are only 1,260 shares in the mine, which are owned by three individuals, Redington, Livermore and Cornwall. It was considered a good joke on Flood & O'Brien to be caught in the $1.50 per pound contract, but it happens that such old birds in the business are not caught with chaff, and they have probably had their quicksilver cheaper than most other mines.

Improved Grinding Mills.

Geared mills with vertical spindles, save the inventor of the improved mills illustrated in the annexed engravings, are going out of use. Their toothed wheels or cogged gears are too rough in running and too expensive, while spindles in a vertical position do not run well, because they cannot be kept thoroughly oiled, and do not lie steadily against their bearings. Almost all the shafting used for driving machinery is now horizontal, with vertical pulleys, and therefore the driving pulleys of grinding mills should obviously also be vertical, in order to be as convenient as possible to set up and put in operation.

In constructing the mills represented, the horizontal shaft was the inventor's main object; but subsequent experiment showed him other and superior advantages attaching to the form. The machines became more quiet and light running, but ground more rapidly, while their simplicity evidenced that the extensive repairs required in the use of gearing would be avoided. As now made, the mills are compact and convenient to be driven from portable steam engines or horizontal shafting. The boxes for supporting the spindles are four times longer than are usually made, extending almost through the entire mill; and they carry the runner, which is solidly attached to the spindle, in a true plane with the face of the bedstone.



HARRISON'S GRINDING MILLS.

The runner stones are secured to the spindles by heavy iron connections, and if a suitable proportion of metal is used for this purpose the velocity at which they can be safely run is almost unlimited, and as speed is nearly the only limit to grinding in mills so constructed, it has been demonstrated a hundred times over that these burrs of only 20-inch diameter and 500 pounds weight, excel in working capacity the common four feet stones.

Millstones and the framework on which they are usually mounted are liable to be broken by hard substances passing through the mills, which in many cases have proved destructive to life and limb. To avoid such accident, the inventor constructs his mills so that they may be readily adjusted to any desired strain; and should nails, slugs, or bolts go through the stones, the latter immediately return to their places with such accuracy that no stoppage of the machine is required, but the working position is kept, and all delay avoided.

It is claimed that anything, however hard or ungrindable, which will pass through the eye of the stone will pass out without injury to the stones or mill. In order to accommodate different articles, which require more or less strain in grinding, and each needs a pressure peculiar to itself, the mills are provided with safety springs, which can be readily adjusted or changed to suit. These are also applicable to change of pressure, needed according to the quantity to be ground, as of course it takes more working pressure to grind fifty bushels than ten bushels of meal per hour. A common working speed for the 20-inch mill is 1,400 turns per minute, and 1,000 turns for the 30-inch mill.

The small portable burrstone mills grind fifty bushels of good meal per hour, as regular work, from day to day, and have averaged as high as eighty bushels. This, the inventor claims, is due to the peculiar mode of mounting and dressing the stones, their facility for receiving grain at the eye, and the ease with which the meal passes out of the new discharge spouts. It is due also to the vertical position of the stones, the extraordinary velocity at which they run, and to such an adaptation of speed to grinding surface that, when the meal is once properly ground, it is thrown out and does not clog the furrows and consume the driving power. The inventor has submitted written certificates as to the above mentioned capabilities of his mill. He further states that over 9,000 machines were sold up to the beginning of the present year.

The engravings show two different types of mill, the principal points of difference being the styles and sizes of frames for supporting the spindles and working parts and the number of bearings required, the construction and mode of adjusting the spring bearings by means of which the pressure of the stones is automatically controlled. The mills are adapted to all varieties of grinding and for every substance, whether wet or dry, hard or tough, heavy or light, brittle or fibrous. Several sizes of this machine are made.

The strength and durability necessary to enable these mills to be run safely at a very high velocity, is secured by the employment of the best materials, metal and stone only being employed in their construction. They are delivered to purchasers ready for use and in complete running order. For further information address the inventor and manufacturer, Mr. E. Harrison, New Haven, Conn.

THE Virginia *Chronicle* learns that a small gang of mining-claim jumpers are now preparing for a spring campaign in the business of jumping town lots and mining claims.

LUMBER is no longer a scarcity in Virginia City.

The Fryer Process.

Public interest in the Fryer process continues unabated, and has perhaps been more excited the past week, by some slight inklings as to the rationale of the process. Several gentlemen of Grass Valley, including the editors of the local papers, have been allowed to examine the works and see the details of the process, and they pronounce it a success, but do not explain the arrangements. The Nevada *Transcript* man describes the "chemicals" used in a facetious scientific manner, calling charcoal and air such names as not to be recognized by the uninitiated, and such other descriptions as have appeared throw no more light on the subject.

As Mr. Fryer has been in town this week we called upon him and were shown drawings of the furnace used and had the preliminary operations described to us, together with the working of the furnace. The furnace is peculiar in several points, and Mr. Fryer assures us that it will roast four tons of ore with one cord of wood, taking a charge every four hours; larger or smaller furnaces can of course be used. The principal points of the process are dependent upon the novel treatment of the rock after leaving the furnace; but this part is kept secret until the foreign patents are secured.

Mr. Fryer tells us that he can reduce the ore at Grass Valley for $3 per ton; and that it makes no difference to him what class of ore it is, refractory or free. He makes no pretence to metallurgical knowledge outside of his peculiar process, and says he did not know anything about quartz or quartz machinery before he came here. All the men about his works were green hands, no metallurgical expert being employed. He says that any one can try the tailings from his works to see whether he works close or not. With regard to use and loss of quicksilver he informs us that on his arrival at Grass Valley he bought ten pounds of quicksilver to experiment with. When the large works were up he bought a flask; since then several hundred tons of rock have been worked and on his return from the East he weighed the quicksilver, to see how much was lost. He had the whole flask left and eight and a half pounds of the original ten.

In the process we are informed that the pulverizer, amalgamating and concentrating machinery are all new, as is the furnace. No water is used until in the last stages. Further than this we are ignorant, as Mr. Fryer does not wish to make his secrets public until his patents are fully secured.

It would be useless to give any description of the furnace and part of the process without the whole thing. We have Mr. Fryer's authority, however, for saying that within a few weeks at most the whole process will be described in the MINING AND SCIENTIFIC PRESS, with detailed engravings of the machinery and furnace. We shall give a full account of the whole thing with Mr. Fryer's explanations, and until then any comments on the process, of the details of which we are ignorant, would be superfluous. We are told that the whole expense of an outfit for twenty tons per day will be about $15,000. The machinery will all be made in this city, although the headquarters of the company will be for the present in Grass Valley.

As soon as the engravings are prepared and the pending patents issued, the Fryer process will be fully described in this paper, due notice of which will be given.

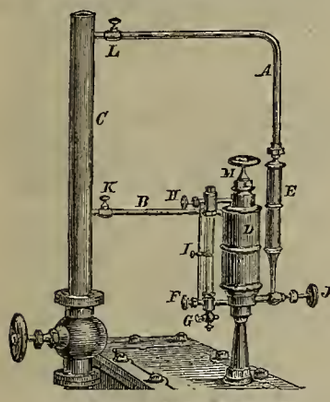
Machinery.

N. Seibert's Eureka Lubricators.

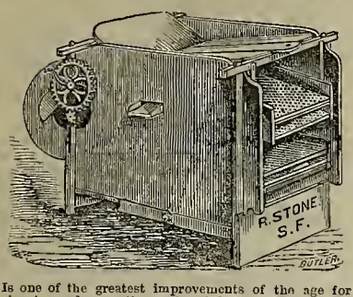


THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stopps; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Manufactured by California Brass Works, 125 First street, S. F. 24v23

THE PATENT
Novelty Mill and Grain Separator



Is one of the greatest improvements of the age for cleaning and separating grain, while it combines all the essential qualities of a first-class Fanning Mill. It also far excels anything that has been invented for the separation of grain. It has been thoroughly tested on all the different kinds of mixed grain. It takes out Mustard, Grass Seeds, Barley and Oats, and makes two distinct qualities of Wheat if desired. For further information, apply to

SAVE YOUR HORSE'S FEET!

NO MORE RASPING AND HAMMERING TO CLINCH HORSE-SHOE NAILS. TENDER FOOTED HORSES SHOD WITH EASE. EVERY TEAMSTER HIS OWN BLACKSMITH.

The new patent implement used is an attachment to an ordinary pair of pincers. A scoop-shaped graver, or chisel, and a flattened, roughened plate, (formed in one piece) are hinged and fastened on to the handle of the pincers. When the forceps are closed the graver projects from one side of the handle, and is retained in that position by allowing the end of the plate to enter a slot between another plate on the other handle, and the handle, thus holding the graver steadily, while the forceps are grasped by both hands, and the grooves cut in the hoof below the point where the nails come through. When the grooves are cut the handles are opened, and the roughened plate turned outward, thus carrying the graver into a slot in the socket, out of the way.

To clinch the nails after the grooves are cut, the handles are opened, and the roughened plate is put beneath the hoof. The edge of a steel plate on the handle of the forceps is then placed above the nail point, and by closing the handles the nail will be bent down into the groove already cut, where it lies nearly flush with the hoof. The plate can be adjusted for large or small hoofs. The groove cut by the graver is about one-eighth of an inch long and one-eighth of an inch wide. No hammering or rasping is necessary. The foot is not bruised or scarred. Any one can learn to use it in a few minutes. Tender-footed horses can be shod with no pain to them. Further information given, if desired, by CARLES R. DONNER, Inventor, or C. F. SUHL, Cor. Commercial & Drumm Sts., S. F. eowhp

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.

It is unequalled for cleansing Woolen Fabrics, Cutlery, Carpets or Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing.

It renders water soft, and imparts a delightful sense of coolness after washing.

DIRECTIONS.—For Laundry, use two to four tablespoonfuls to a washtub of water. For bathing, use one tablespoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterward. For stimulating the growth of plants, use a few drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.

Also, SULPHATE OF AMMONIA for chemical purpose, fertilizing, and the preparation of artificial manures. AMMONIACAL PREPARATION, for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing, and PURE LIQUOR and AQUA AMMONIA for chemical and pharmacentical purposes.

54 BUSHELS OF CORN AN HOUR.
HARRISON'S
LIGHT, VERTICAL BURR MILLS
BARBER & BACON, MILLERS AND LUMBER DEALERS, SOUTH VERNON, VT., write July 15th:
"We have been running two of your LIGHT VERTICAL CORN MILLS for the past 6 months with remarkable results, and have ground over 80,000 bushels of corn into No. 1 meal in that time, running the grist-mill nights only, as we run our saw mill in the day time. We have often ground in the 20-inch Mill (which weighs about 500 lbs.), 1,000 lbs. of corn in twenty minutes, or 54 bushels in one hour. Our usual night's work is about 24,300 lbs., or 434 bushels. To do this we have to run at a speed of 1,300 turns per minute, and use about a 20-horse power. You may refer parties to us for further information, and when we have tested your HEAVY VERTICAL MILL, we shall take great pleasure in giving the results."

At a Stated Term of the Circuit Court

of the United States of America of the Ninth Judicial Circuit in and for the District of California, held at the court room in the city and county of San Francisco, on Thursday, the 30th day of September, in the year of our Lord one thousand eight hundred and seventy-five. Present—The Honorable Lorenzo Sawyer, Judge.

Nicholas Selbert, complainant, vs. Wm. T. Garratt, defendant—In equity.

DECREE.

This cause came in to be heard at the February Term, A. D. 1875, of this Court and was argued by counsel and thereupon upon consideration thereof, it was ordered, adjudged and decreed, as follows, viz: That defendant, William T. Garratt, was not the first or original inventor, or discoverer of the improvement or discovery claimed by him, in and by those certain reissued letters patent of the United States, numbered five thousand three hundred and twenty-eight (No. 5328), for an alleged new and useful improvement in lubricators, issued to said defendant, William T. Garratt, on the 16th day of March, A. D. 1873, and is not entitled to a patent therefor, and that said reissued letters patent, number five thousand three hundred and twenty-eight (No. 5328) are declared void and the same are hereby vacated and set aside by reason of their interference with those certain letters patent of the United States, number one hundred and eleven thousand eight hundred and eighty-one (No. 111,881) for a new and useful improvement in lubricators, issued to complainant, Nicholas Seibert, on the fourteenth (14th) day of February, A. D. 1871.

It was also further ordered, adjudged and decreed that complainant do have and recover of and from defendant his costs and expenses to be taxed herein.

(Signed) LORENZO SAWYER,
Circuit Judge.

The above decree has reference to "Seibert's Eureka Lubricator" for oiling the valves and cylinders of steam engines.

It has a glass gauge and condensing pipe, or reservoir, with a regulating feed valve, and works as follows: As the water of condensation is admitted, under the oil, just so fast the oil passes out at the top through a pipe into the steam pipe to oil the valves and cylinder.

Parties who infringe or purchase the infringed lubricators, will be held strictly responsible.

N. SEIBERT, Patentee,
125 First Street, S. F.

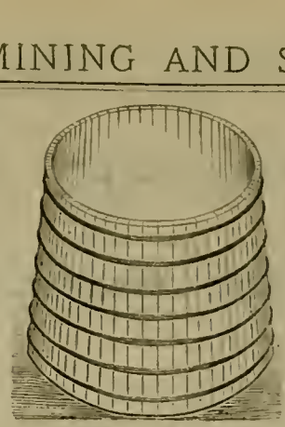
Mining Superintendent

Of fifteen years' experience in working the most rebellious ores on the continent, desires employment. The gentleman thoroughly understands the opening and development of mines, and the construction of all kinds of machinery and appliances for the reduction of ores, and especially those termed rebellious. Can be communicated with through this office.

MINING ENGINEER.

A Mining Engineer, with the best of best of references, thoroughly experienced in the opening and superintending of mines and mills, desires an engagement. Address, "MINING ENGINEER," MINING AND SCIENTIFIC PRESS Office, San Francisco.

GIVE YOUR FULL ADDRESS when you communicate on business to this office, especially in returning newspapers. The fact that your name is on our subscription list is of no assistance to us. Without sending your post office address we should have to look over thousands of names to find yours.



WATER TANKS of any capacity, made entirely by machinery. Material the best in use; construction not excelled. Attention, dispatch, satisfaction. Cost less than elsewhere.

WELLS, RUSSELL & CO.,
Mechanics' Mills, Cor. Mission & Fremont Streets.

Mining and Other Companies.

Lake Mining Company — Location of

principal place of business, San Francisco, California. Location of mine and works, Quicksilver Mining District, Napa County, California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 4) levied on the third day of November, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
J H Goodman	25	2	$40 00
J H Goodman	31	10	200 00
P Christiauson	35	10	200 00
James Lefferts	*unknown	8	160 00

*All the Company's records having been burned.

And in accordance with law, and an order of the Board of Directors, made on the third day of November, 1875, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the Company, No. 19 First street, San Francisco, Cal., on Monday, the twenty-seventh day of December, 1875, at the hour of 3 o'clock P. M. of said day, to pay the delinquent assessment thereon, together with cost of advertising and expenses of sale.

R. F. KNOX, Secretary.

Office, 19 and 21 First street, San Francisco, Cal.

Mariposa Land and Mining Company of

California. Location of principal place of business, San Francisco, Cal. Location of works, Mariposa County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the thirteenth day of November, 1875 an assessment, (No. 3) of one dollar per share was levied upon the capital stock of the corporation, payable immediately, in United States currency, to the Secretary, at the office of the company, room 33, Nevada Block, No. 309 Montgomery street, San Francisco, Cal., or to the Assistant Secretary, at the office, No. 9 Nassau street, New York City, N. Y.

Any stock upon which this assessment shall remain unpaid on the thirty-first day of December, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the first day of February, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

LEANDER LEAVITT, Secretary.

Office, Room 33, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

Owyhee Water and Gravel Mining Company.

Location of principal place of business, San Francisco, Cal. Location of mines, Elko County, Nev.

THE RISDON

Iron and Locomotive Works,

INCORPORATED.....APRIL 30, 1868.
CAPITAL.....$1,000,000.

LOCATION OF WORKS:

Corner of Beale and Howard Streets,

SAN FRANCISCO.

Manufacturers of Steam Engines, Quartz and Flour Mill Machinery, Steam Boilers (Marine, Locomotive and Stationary), Marine Engines (High and Low Pressure). All kinds of light and heavy Castings at lowest prices. Cams and Tappets, with chilled faces, guaranteed 40 per cent. more durable than ordinary iron.

Directors:

Joseph Moore, Jesse Holladay, C. E. McLane,
Wm. Norris, Wm. H. Taylor, J. B. Haggin,
James D. Walker.

Sold by all the principal hardware stores on the Pacific Coast. 18v25.1y

Important in regard to Pumps.

Aurora, Nevada, November 10, 1875.

H. P. Gregory & Co., San Francisco.

Gentlemen: I am exceedingly well pleased with the "SPECIAL PATTERN BLAKE MINING PUMP" and its workings; especially so with the "MORTON EJECTOR CONDENSER." Have both in position on 400 foot level. The condenser is doing all that is recommended, and is saving from one and one-half (1 1-2) to one and three-quarters (1 3-4) cords of wood per day, I consider it a very useful improvement.

Yours Respectfully,

Warren Rose, Supt. Juniata Cons. S. M. Co.

We are prepared to put in the "BLAKE IMPROVED STEAM PUMP" in connection with the "MORTON EJECTOR CONDENSER" and fully guarantee a saving of from thirty to forty per cent. over any other direct acting Steam Pump in use.

H. P. GREGORY & CO.,

14 and 16 FIRST STREET, SAN FRANCISCO.

Send for Catalogue and Descriptive Circulars.

PACIFIC MACHINERY DEPOT,

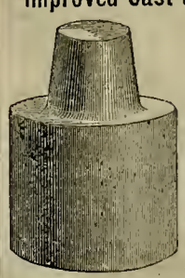
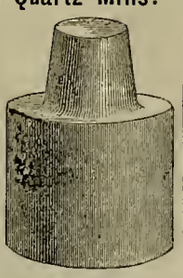
310 California Street, - - - - - San Francisco.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.





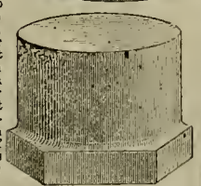
[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.



Address all orders, with dimensions, to W. R. Townsend, Secretary.

1y29-3m CAST STEEL SHOE & DIE CO., Room 4, Academy Building, S. F

SAVE $50! WHY PAY $85?

SEWING MACHINES.

REDUCED PRICE, $35.

HOME and HOME SHUTTLE SEWING MACHINES.

Reduced to Live and Let Live Prices.

These Machines are superior to any and all; nice sewers, straight needle, two threads, shuttle, lock-stitch, the simplest and cheapest, and the lightest running first-class Machines in the market. To see is to convince yourselves.

The Hall Treadle for Sewing Machines,

The most important improvement ever made. It saves labor and preserves health. No more diseases and deaths, side or back aches from using Sewing Machines. No teaching required. A child can run it. Always starts the right way. Never goes backwards and breaks things. Can be stopped instantly. With it on your Machine, you can do double the work you can without it. Fifty stitches can be made with one pressure of one foot. It can be applied to any Sewing Machine. Approved by Massachusetts State Board of Health (see Official Report 1872), Massachusetts Medical Society and Massachusetts Charitable Mechanics' Association. The HALL TREADLE is a part of all HOME MACHINES sold by us.

The Hall Treadle Grinding Machine

Must be seen to be appreciated. For a Farmer or Mechanic to see it, is to buy one. It is an indispensable article in every Farm-house, Shop or Hotel.

The Hall Treadle Jig Saw and Boring Machine

Is an accomplishment in every Workshop. The HALL TREADLE is applicable to all machinery requiring foot-power—Sewing Machines, Grindstones, Jig Saws, Turning Lathes, Jewelers' and Dentists' Lathes, etc Send for Circulars.
